Multiple sclerosis (*q.v.*) is a disease in which a number of limited areas or plaques of nerve fibre degeneration occur with consequent local scarring. Its exact etiology is unknown, but one view considers it a primary virus disease with secondary effects of an allergic nature in the nervous system. The disease attacks both brain and spinal cord, but there is a form that presents clinically as a purely spinal disease, causing mainly stiffness, weakness and in-co-ordination of limbs and trunk. The condition is then often benign and slowly progressive.

Motor neuron disease (*see* AMYOTROPHIC LATERAL SCLEROSIS) is essentially a degenerative condition, again of unknown cause, that affects the motor nerve cells or neurons, upper and lower, selectively. It may be present as cord disease because motor tracts in the cord, as well as the motor cells, are affected. The result is weakness and wasting of muscles, but with no sensory change. As the lower motor cells in the cord become diseased, a characteristic flickering (fasciculation) occurs in the muscles innervated by them.

Another degenerative disease, *syringomyelia*, causes cavitation in the centre of the cord. As this cavity enlarges, first the sensory fibres for pain and temperature are involved, then motor tracts and finally other sensory tracts. This sequence gives a characteristic picture at first of loss of pain and temperature sense dissociated from loss of other sensation.

Syphilis (*see* VENEREAL DISEASES: *Syphilis*) of the nervous system usually affects both brain and spinal cord. However, it may produce a mainly cord disease in which sensory tracts (posterior columns) are especially affected. The condition—*tabes dorsalis* (*q.v.*)—is characterized by widespread loss of proprioceptive sensation, with consequent interruption of the reflex arc subserving tendon jerks, which are abolished, and by variable areas of pain loss. A particular change in pupillary reactions by which the pupil is small and constricts to accommodation but not to light (the Argyll Robertson pupil) and some degree of optic atrophy usually accompany tabes dorsalis and aid the diagnosis. This, however, is most firmly established as in all forms of neurosyphilis by the serological reactions (Wassermann reaction, etc.) in blood and cerebrospinal fluid.

Finally a number of degenerative and often familial diseases occur in which various tracts in the cord are selectively diseased. Thus, differing combinations of losses of motor, reflex and sensory function and co-ordination causing ataxia result. The group is referred to as *Friedreich's ataxia* and its variants.

Brain Disease.—The brain may be generally diseased by such factors as inflammation, toxins or degeneration, or it may be locally affected, *e.g.*, by injury or tumour. In the first case there will always be some change in psychological function such as memory, concentration or emotional reactions. This is because the brain is the organ of adaptive behaviour; whatever the ultimate substrate of thought and emotion may be, in man they are not experienced in the absence of the brain. In local brain disease there may be little or no mental change, but local loss of neurologi-

cal function in some part of the body occurs and may indicate the exact site of the brain disease.

Acute *encephalitis* (*q.v.*)—inflammation of the brain—is usually caused by virus infections, less often by bacteria. It may be abrupt in onset or slowly ingravescent and results in delirium, stupor and coma. It involves most parts of the brain and there are rarely any local neurological abnormalities. As recovery occurs, however, and general changes in consciousness subside, local abnormalities may be revealed.

At the other end of the scale, a slow, generalized degeneration of brain cells may occur, causing increasing dementia and restriction of the normal range of behaviour. This so-called *presenile* dementia is probably genetically determined though its exact cause is unknown (*see* also DEMENTIA). A similar generalized loss of cerebral function may occur with arterial disease of the brain, with cerebral syphilis or with advanced and widespread disseminated sclerosis. When the brain is repeatedly injured, as by blows on the head, even though each individual injury is slight, a cumulative effect may again produce a general mental slowing and loss of cerebral function exemplified in the "punch-drunk" condition. Sometimes, in cerebral tumour, although the disease is quite localized, it produces a general rise in intracranial pressure, since the skull and brain membranes (meninges) form a relatively inexpansible container. Inflammation of the meninges may cause adhesions and loss of normal circulation of the cerebrospinal fluid filling the cerebral ventricles and bathing the surface of the brain, with consequent rise in pressure. Such adhesions may be a prominent feature of *tuberculous meningitis* (*see* MENINGITIS: *Nonsuppurative Meningitis*). In these cases again, symptoms of general cerebral dysfunction occur. When disease is strictly limited to certain regions in the brain stem, it may sometimes produce quite general symptoms by interfering with some alerting mechanism necessary for proper cerebral and especially mental function.

When local brain disease occurs, its exact site determines local symptoms. The cerebral cortex on each side of the brain contains areas representing motor and sensory function on the opposite side of the body, since sensory and motor fibres cross, some in the cord but most in the medulla oblongata. The most posterior, or occipital, part of the cortex is concerned with vision. More anteriorly, but still posterior to the great fissure of Rolando (central sulcus) of the cortex, various forms of common sensation are represented, while farther forward the pre-Rolandic area governs motor function. The two lateral halves of the cortex are not quite equipotential, for one half (the left half in right-handed people), often called the dominant hemisphere, is involved in understanding and execution of speech and writing. Lesions in limited areas of the frontal and posterior temporal regions of this hemisphere cause a variety of losses of organized speech called dysphasias, or aphasias (*see* also SPEECH DISORDERS: *Aphasia* [*Dysphasia*]). There are also areas of the cortex that control important but less clear-cut functions. Areas in the parietal lobes are linked with recognition of the significance and meaning of objects, orientation of the body in space and recognition of the constituent parts and positions of outside space. These functions are shared by the two hemispheres. The anterior or frontal poles of the cortex seem associated with general manifestations of emotion and personality, as do the medial parts of the temporal lobes. Local lesions in these areas will cause localized changes in the functions represented. The commonest cause for such local lesions is cerebral tumour. Injury, local vascular disease and abscess may also be responsible.

Apart from loss of function, however, the cortex may react to disease by producing sudden abnormal discharge of nerve cells, resulting in an *epileptic fit*. Focal fits take the form of a sudden involuntary sensory or motor change in part of the body or in the special senses—smell, taste, vision and hearing. In generalized fits consciousness is abruptly lost and the whole body is seized by *convulsions* (*q.v.*). Focal fits are a valuable indication of which part of the brain is diseased. Besides appearing as a local disease, epilepsy may occur (sometimes focal but more often generalized) as a special disease (*see* EPILEPSY). In this condition (idiopathic epilepsy) there is usually a genetic factor and a family history reveals other cases.

In disease of subcortical or basal parts of the brain, various abnormalities of movement occur: there may be slowing and loss of fine movement with tremor and rigidity as in *Parkinson's disease* (*see* PARKINSONISM); sudden involuntary jerks may interrupt normal smooth movement as in *chorea* (*q.v.*); or movement may become writhing or flail-like as in *athetosis* (*q.v.*). Such diseases are most commonly degenerative in origin, though a form of encephalitis (*encephalitis lethargica*), of which there was a pandemic in 1918, gave rise to a number of cases and *rheumatic encephalitis* may also be responsible for some.

Diseases of the cerebellum result in ataxia of movement—walking, limb movements, speech and eye movement may all be affected. This may be degenerative as in disseminated sclerosis but tumours of the cerebellum or of nearby structures causing cerebellar compression are also common.

In the brain stem, pons and medulla oblongata, where the various tracts to and from the brain are passing down to join the spinal cord, lesions tend to produce interruptions of these tracts with consequent loss of sensory and motor function below, together with loss of function of cranial nerves, which supply the special senses and sensation and movement to the face, head and neck. When such lesions are tumours, they are also liable to produce a general rise in intracranial pressure.

Diagnosis of Nervous System Disease.—Apart from the symptoms and signs shown by clinical examination and the history of how they developed, there are some special tests that are widely useful in neurological diagnosis. The electroencephalograph records the electrical activity of the brain through the intact skull and can detect localized or lateralized abnormalities from tumours, local atrophies, vascular changes, etc., as well as certain generalized changes from metabolic upsets, raised intracranial pressure or intrinsic abnormalities due to idiopathic epilepsy (*see* ELECTROENCEPHALOGRAPHY). X-rays of the skull and spine may reveal bony changes that are affecting underlying nervous tissue in brain, spinal cord or nerve roots. The cerebrospinal fluid may be withdrawn at lumbar puncture; changes in the pressure, constitution and cell content of the fluid may indicate the nature of the disease process. The fluid may also be withdrawn and replaced by a small amount of air, which will pass into the ventricles and parts of the space on the surface of the brain that are usually filled by the fluid. X-rays will then show an outline of the air-filled portions, since air is much less opaque to X-rays than is brain tissue or the fluid. The resulting picture (an air encephalogram) will reveal local distortions or general changes in ventricular and brain surface shape and size. Equally, lumbar fluid may be replaced by a few millilitres of an X-ray-opaque iodized oil and a series of X-ray pictures (myelograms) may be taken that will outline the shape and size of the spinal cord and reveal any obstruction to the fluid flow (*see* also RADIOLOGY: *Skull, Brain and Spinal Cord*). The rate of conduction of impulses in certain peripheral nerves can also be measured electrically (electromyography); local loss or reduction of conduction can determine the exact site of the lesion. Finally, the electromyogram can sample the electrical activity of muscles and sometimes determine whether weakness and wasting are due to disease of the nerves supplying them or to intrinsic muscle disease. *See* also DIAGNOSIS and references under "Nervous System, Disease of" in the Index.

NERVOUS SYSTEM, SURGERY OF. This article discusses the surgery of the human nervous system, taking up the major subdivisions of the subject in the following order: brain, spinal cord and sympathetic and peripheral nerves. For information about the anatomy of these structures, *see* BRAIN; SPINAL CORD; NERVE.

Brain.—Evidences of surgical operations on the skull have been found in the skeletons of prehistoric man and of peoples of many later eras. Such procedures cannot be considered brain surgery

since they rarely, if ever, were carried deeper than the cranial bones, for experience taught the ancient physicians that penetration of the tough sheath (dura mater) covering the brain was usually fatal because of infection by bacteria—a phenomenon not understood until a century ago. Only when operations were carried out under conditions that minimized the likelihood of bacterial invasion could brain surgery develop.

The early success of this type of surgery was hampered by a lack of knowledge of the localization of function within the brain and spinal cord. In order to know where to make an opening through the skull to expose diseased tissue, the surgeon had to be able to interpret properly the symptoms and signs of disease of the nervous system. In the first place, the fact that one side of the brain controlled the movements and sensation of the opposite side of the body had to be firmly established. Then, the principle that certain parts of the brain had to do with movement, others with common cutaneous sensation and still others with vision and audition had to be proved. Later the location of these areas in the cortex of the big brain, or cerebrum, was demonstrated. When the neurologist knew that a blindness in the right half of the visual field in both eyes was associated with derangement of the left occipital (back part of the brain) lobe, he could then decide if the condition might be relieved by an operation and could indicate precisely where the surgeon should make a hole in the skull to find the trouble.

Techniques for Detecting Abnormalities.—Other means soon became available, however, for detecting abnormal conditions in the brain. With these techniques the surgeon is able to locate the diseased places within the head and to plan his operation accurately.

Soon after the discovery of X-rays, photographs were made of the head with those rays. In these pictures the structure of the skull bones is seen and brain conditions that involve the cranium can be recognized. But since this technique shows changes in bone only, methods by which the brain itself could be visualized had to be devised. Within the cerebrum are cavities, or ventricles, containing a watery fluid (ventricular fluid); this fluid passes about the base of the brain and is absorbed by the veins on the surface of the hemispheres. Normally these cavities are symmetrical on the two sides and have a fairly constant shape. But in the presence of a tumour or other disease of the brain they may be distorted. If the fluid is removed from the cavities with a needle and is replaced by air, an X-ray photograph of the head will show the ventricles, for the X-rays pass more readily through air than brain and hence more rays reach the film through the ventricles and therefore fog their outline. This technique is termed ventriculography (or if the air is injected through the spinal canal, pneumoencephalography).

Another method of showing the contour of the brain utilizes an injection of a radiopaque dye (one that stops X-rays) in the neck (carotid) artery at the time that an X-ray photograph is made of the head. This outlines the arteries of the brain, which usually have a constant position, and will show any displacement of the vessels or any collection of abnormal blood channels within the brain. This technique is called cerebral angiography.

When it was found that normal brain activity is accompanied by changes of electrical potential that can be detected by leading wires from different places on the scalp, another means of demonstrating the location of brain disease became available. The changes in potential normally occur at constant and identical frequencies (8 to 11 per second) on the two sides of the head. Unusually slow, fast or sharp waves often indicate abnormalities in the brain; a disturbance in electrical activity localized in one area usually means that that part of the brain is diseased. This technique, called electroencephalography (*q.v.*), is particularly useful in studying the epilepsies. (*See* EPILEPSY.)

When radioactive isotopes were produced for use in medicine, another tool for determining the location of disease within the brain became available. Diagnostic use of the isotopes is based on the fact that tumours of the brain take up or accumulate greater amounts of certain radioactive substances than does normal brain tissue. Several hours after the irradiating isotopes of these substances (*e.g.*, iodine) are given to the patient, a detecting tube is passed over the head to determine the areas of maximum discharge of gamma rays from the isotope. The findings from this process, known as brain scanning, can be recorded on paper or photographic film over an outline of the head.

Exposing the Brain.—The purely mechanical procedure of uncovering the brain taxed the ingenuity of the first brain surgeons, for the control of bleeding from scalp arteries, which retracted when cut, and from skull bones was a serious matter. The early surgeons attempted to stop the bleeding from the scalp vessels by tying a tight band around the head just above the ears. Later, clamps were applied to the layer of fibrous tissue just beneath the blood vessels and turned back over the scalp to choke off the bleeding vessels, or clips were applied to squeeze the vessels between the scalp and fibrous layer. This fibrous layer is loosely attached to the underlying outer covering of the skull bone; it was in this plane that the American Indians scalped their victims.

To expose the hard coverings of the brain, the skull was perforated by a trephine—a tool similar to a carpenter's brace and bit—and the hole enlarged by rongeurs, an instrument similar to a pair of pliers but with cutting edges on the jaws so that the bone can be bitten away. However, this left a hole in the skull after recovery that sometimes caused headache and alarmed the patient for fear a fall or blow might damage the brain.

The hole technique has been replaced in recent years by a trap door in the skull (technically called a bone flap) that is made by boring holes about 4 cm. apart around the area to be exposed (fig. 1). Usually the base of the flap is at the margin of one of the muscles attached to the lower part of the skull. The bone between

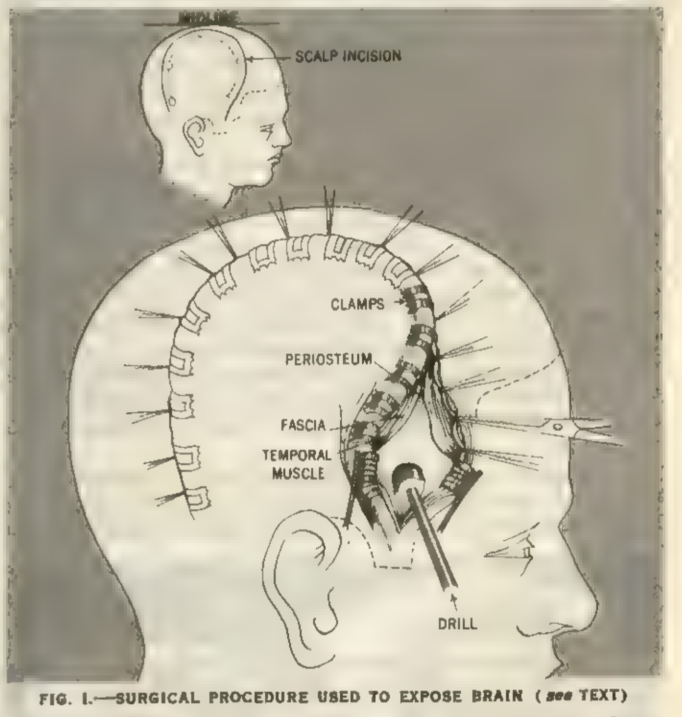

FIG. 1.—SURGICAL PROCEDURE USED TO EXPOSE BRAIN (*see* TEXT)

the holes away from this base is cut with a wire saw so that a horseshoe-shaped piece of bone is free except beneath the muscle. By prying up on the bone, the base of the flap is broken and the entire piece attached to muscle is then lifted up and turned away from the dura mater of the brain, using the muscle as a hinge. The edges of the cut bones are plugged with wax to stop their bleeding. Thus a large area of dura mater is uncovered, and the underlying brain can be easily exposed by cutting the dura mater with a scissors around most of the margin of the bony opening. The cortex, which is covered by the transparent pia arachnoid, or soft membrane, is thus brought into view (fig. 2).

After the operative procedures on the brain have been completed, the dura mater is usually sewed together to cover the brain (fig. 3). The bone flap is replaced and held by a wire suture that is passed through the adjacent outer and inner margins of skull bone. The cut margins of the muscle at the base of the flap are

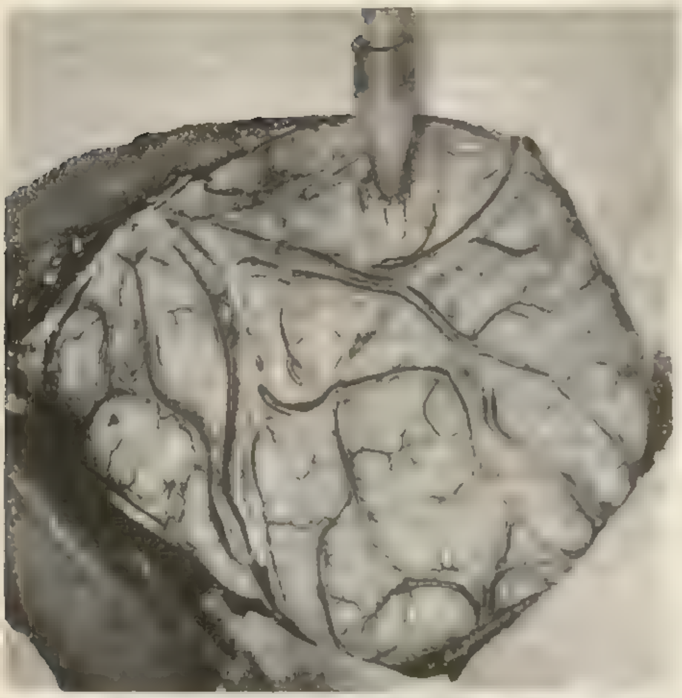

FIG. 2.—BRAIN AFTER OPENING OF DURA MATER

sewed together. Then the deep layer of fibrous tissue of the flap is stitched to the same layer of the scalp, usually with silk thread. Finally the superficial margins of the incision are brought together by sutures tied on the surface. Thus the scalp edges are held together in apposition so that they can heal. The cutaneous stitches may be removed in three to seven days.

Occasionally if a tumour cannot be taken out completely, pressure inside the head is relieved by (1) removing the lower portion of the bone flap under the muscle and the temple bone adjacent to the flap, and (2) incising the hard coverings of the brain in a radiating manner so as to leave a defect through which the brain can protrude and press against the temporal muscle. The remainder of the bone flap is then replaced and wired in place, and the muscles and scalp are closed as described above. The decompression left beneath the muscle will prevent too great an increase in pressure inside the head, and yet the muscle will tend to keep the protrusion on the side of the head from becoming too large and unsightly.

In certain operations when only a small hole in the skull is necessary and when the proposed opening is covered by muscle, the bone is perforated by a trephine and the opening enlarged to the

desired size by a rongeur. Such holes are usually made beneath the temporal muscle or the heavy neck muscles; consequently when the muscles are sewed together they cover (and protect) the defect so that it is barely, if at all, visible.

Excision Procedure.—The surgical procedures thus far discussed allow the surgeon to expose and inspect the brain. Depending upon the disease condition—a tumour, abscess, scar or other abnormal state—the surgeon then proceeds to explore the brain or excise the diseased area. First, the many extremely small vessels in the soft covering of the brain are usually shrunken and cut with a high-frequency electric current. The underlying brain tissue, which has the consistency of a soft cheese, may be cut through with a blunt instrument and a large piece of diseased tissue removed.

Usually it is not desirable to cut into the motor cortex, the area of the cortex that controls movements, because doing so may leave the patient paralyzed on one side and speechless.

The extent and type of the surgical procedure depends on the abnormality present in the brain. Some tumours do not invade the brain and may be removed completely. Some are invasive and only a portion of them can be excised to relieve the pressure within the skull. Abscesses usually may be removed without difficulty. Scars that cause epilepsy can often be removed completely; the abnormal tissue at the scar margins, which is responsible for the convulsions, can be mapped accurately by applying electrodes to the surface of the cortex and making a record of the brain activity during the operation (fig. 2).

Many other types of brain operations may be done; for example, the outpouchings (aneurysms) of blood vessels that sometimes rupture and cause serious hemorrhages into the brain may be clipped at their base, leaving the flow of blood in the parent vessel intact. Nerves at the base of the brain may be cut to relieve excruciating pain or bouts of dizziness. Needles can be inserted under X-ray control to destroy the deeper nuclei of the brain and thereby abolish the tremor or relieve the stiffness of a shaking palsy. Finally, the normal contour of the head may be restored by filling holes in the skull bones with pieces of bone from the patient's hip or rib or with sheets of tantalum or plates of molded plastic.

Spinal Cord.—As soon as aseptic techniques and anesthesia were developed, the surgeon cut through the bony coverings of the spinal cord—the spinous processes and laminae of the vertebrae—and removed them with the rongeurs to expose the hard membrane. A longitudinal incision in the spinal dura mater brings into view the transparent soft coverings and the cord. Tumours that do not invade the spinal cord usually are removed easily. Invasive tumours may be partially removed and the dura mater left unsutured to relieve pressure on the nerve tracts in the cord. At times, the surgeon cuts a part of the spinal cord (cordotomy) to relieve pain in the lower parts of the body. At other times the nerve roots entering or leaving the cord are cut to eliminate pain or muscle spasms. Spinal injuries that fracture the vertebrae may or may not damage the spinal cord and may cause varying degrees of paralysis. In most instances conservative measures such as a cast and the posturing extension of the spine are the only forms of treatment required. A decompressive laminectomy (excision of a lamina) is occasionally indicated if the spinal cord is compressed by blood clots or by bone fragments. Paraplegia that results from severe injuries requires a long period of rehabilitation and training but some patients make a remarkable adjustment to their disability and become economically self-supporting.

An important phase of neurosurgery is the treatment of sciatic and arm pain by the removal of the protruding cartilaginous material (disc) that normally acts as a cushion between each vertebral bone. When this disc is broken as result of injury or degeneration from chronic wear and tear, it may stick out at the side of the vertebra and press against a nerve root, causing pain in the leg if the protrusion is of a disc of the lower back or in the arm if it is of the neck. Such protrusions are easily exposed surgically by separating the muscles from one side of the spinous processes and laminae at the involved site. The removal of a small portion of the adjacent laminae allows the surgeon to see the com

pressed and displaced nerve root so that it may be retracted to one side and the protruding disc material underneath may then be removed.

At times the disc material degenerates and leaves the back unstable, that is, with unnatural and painful mobility. To relieve this condition the loose joint is fused by plugging it with pieces of bone or by firmly fastening strips of bone along the spinous processes and laminae of the vertebrae on either side of the diseased disc. When new bone forms between these vertebrae the joint becomes solid.

Improper or incomplete development of the spinal cord and its coverings occurs occasionally and produces a mass on the back that contains a watery fluid surrounding incompletely developed nerve roots or spinal cord. If the failure of growth has not been too severe the surgeon may make a new covering for the cord and nerve roots. Often, unfortunately, the defect is so great that the patient is paralyzed in the legs and has no control over the bladder or bowel. In such cases operation is futile.

Sympathetic and Peripheral Nerves.—A further part of the surgery of the nervous system concerns the sympathetic and peripheral nerves. The former control many of the activities of the abdominal organs, the blood vessels and skin—activities that are automatically modified by the brain in response to changes in the internal or external environment of the individual. Thus in a cold environment the blood vessels of the skin constrict and the hairs stand up to form "goose pimples"; both actions decrease the loss of heat from the skin and conserve it for the body. At times the sympathetic nerves may become excessively active so that the surgeon must remove a portion of them to increase the blood supply of an arm or leg or to prevent spasms of the blood vessels.

The peripheral nerves—those that supply muscles and skin—are subject to the same injuries and diseases as are other tissues of the arms and legs. They must be sutured together after being cut so that their nerve fibres can regenerate and innervate the muscles and skin.

Such operations are relatively simple compared with those of the brain and spinal cord but require a technical skill to obtain apposition of the nerve ends. Even with perfect suturing, severed nerve fibres rarely regenerate so completely that normal muscle function and skin sensation are regained.

NESBIT, EDITH (1858–1924), English writer of books about children whose characters are as clearly defined and true-to-life as is their middle-class home background, with its secure moral values, and whose adventures, whether brought about by family misfortunes or through the workings of magic, are described with a blend of imagination and practicality which carries immediate conviction. She was born in London on Aug. 15, 1858, and educated spasmodically in France, Germany and England. In 1880 she married the Fabian journalist Hubert Bland, and, as they had to live entirely by writing, she poured out novels, stories, poems and articles, including numerous verses and short tales for children, before she found her vocation in depicting the Bastables, one of the most memorable families in juvenile fiction, in the stories collected as *The Story of the Treasure Seekers* (1899), *The Would-be-Goods* (1901) and *New Treasure Seekers* (1904). She attained an even higher level with unconventional fairy tales and magical adventures in matter-of-fact, everyday settings. Collections such as *The Book of Dragons* (1900), *Nine Unlikely Tales* (1901) and *The Magic World* (1912) were surpassed by the trilogy of adventures with the wonder-working "Psammead"—a fat, furry sand-fairy: *Five Children—and It* (1902), *The Phoenix and the Carpet* (1904) and *The Story of the Amulet* (1906). Her most successful tale of magic is *The Enchanted Castle* (1907) and there is little falling-off in *The House of Arden* (1908), *Harding's Luck* (1909) and *The Magic City* (1910). Widowed in 1914, in 1917 she married Thomas Tucker. She died at New Romney, Kent, on May 4, 1924.

NESS, LOCH, Inverness-shire, Scot., the largest mass of fresh water in the United Kingdom (Loch Lomond has the largest area, 27½ sq.mi.), is 754 ft. deep and 22½ mi. long. It is only 52 ft. above sea level, lying in the Great Glen Fault, and is free of ice. The watershed extends to over 700 sq.mi., the loch being fed by several considerable rivers, all known for their salmon fishing. The sharp rise and fall of the level of the loch is one reason for the scanty flora of the waters, the other being the great depths reached near the shore line. The abyssal fauna is also sparse. In common with several other very deep lochs in Scotland and Scandinavia, Loch Ness is said to be inhabited by an aquatic monster, accounts of which have been much publicized. Loch Ness forms part of the system of waterways linked by Thomas Telford in 1824. The village of Fort Augustus lies at the head of the loch and the town of Inverness is within a few miles of its foot. (F. F. DG.)

NESSELRODE, KARL ROBERT, COUNT (1780–1862), Russian statesman, sole foreign minister for 34 years, was born on Dec. 13 (new style; 2, old style), 1780, in Lisbon, where his father, a member of a German family of counts of the Holy Roman empire (with their seat at Nesselrode, near Solingen, in the duchy of Berg) was serving as Russian ambassador to Portugal. Educated in Germany and a Protestant by religion, Nesselrode never quite mastered the Russian language, but at the age of 16 he entered the Russian navy, for which his father had signed him up at his birth. He became naval aide-de-camp to the emperor Paul I, but distinguished himself neither in the navy nor, later, in the army. Early renouncing military life, he entered the diplomatic service, in which he was to make his name.

Between 1801 and 1806 Nesselrode served at the embassies in Berlin and at The Hague; and in 1806 he traveled in southern Germany to report on French troops to the Russian emperor Alexander I. In Germany, meanwhile, he had become acquainted with Friedrich Gentz and with Metternich (*qq.v.*), whose influence made him a strong advocate of Russo-Austrian co-operation. He served as diplomatic secretary to generals M. F. Kamenski, F. W. von Buxhöwden and L. A. Bennigsen in the war of 1806–07 against Napoleonic France, was present at the battle of Eylau (Feb. 1807) and assisted at the peace of Tilsit. He then went to the embassy at Paris, where he acted as intermediary between Talleyrand and Alexander and renewed his association with Metternich. Disagreeing with Count N. P. Rumyantsev, the Russian foreign minister, who wanted to incite the Slavs within the Austrian empire to rebellion, Nesselrode was generally pro-Austrian and anti-French in outlook; but he sought to preserve balance and peace in Europe and, after the breach of diplomatic relations in 1811, tried to persuade Alexander to open negotiations with Napoleon. In the war that followed he served at Alexander's headquarters at Vilna (Vilnius) and was present at the battle of Leipzig. Accompanying the invading army to Paris, he signed the treaty of Chaumont in 1814. (*See* NAPOLEONIC WARS.)

At the congress of Vienna, Nesselrode influenced Alexander to favour the Bourbon restoration and to oppose a ruinous war indemnity on France. Though his prestige was shaken somewhat by the discovery of a secret agreement between France and Austria against Russia, he was appointed director of the college of foreign affairs (1816). On the other hand the actual conduct of foreign affairs was entrusted to Count I. A. Kapodistrias (*q.v.*). Conflicts between Nesselrode and Kapodistrias were reconciled by the emperor himself and Nesselrode accompanied Alexander to the congresses of Aix-la-Chapelle, Troppau, Laibach and Verona. Finally, in 1822, when Kapodistrias in the aftermath of the War of Greek Independence received indefinite leave, Nesselrode became sole minister of foreign affairs, a position in which he remained until 1856.

Under Nicholas I, who succeeded Alexander in 1825, Nesselrode was responsible for the change in policy after 1829 by which the traditional goal of conquering Constantinople was abandoned in favour of keeping Turkey a weak power dependent on Russia (*see* Eastern Question). The treaty of Unkiar Skelessi (1833) realized this change, but it aroused great alarm in Great Britain; and Nesselrode himself negotiated the shelving of that treaty and substituted the alliance between Russia and Great Britain which resulted in the Straits convention of 1841. In 1849 it was he who suggested the decisive Russian intervention in Hungary on Austria's behalf, though he had restrained Nicholas from making an active intervention in France after the revolution of 1848 (as he had likewise restrained him after that of 1830). During the international crisis of 1853, Nesselrode prolonged negotiations as long as he could in the hope of avoiding the Crimean War (*q.v.*). The last of his important political acts, the signing of the treaty of Paris in 1856, at the end of that war, undid the results of his patient efforts to establish Russian preponderance in the Balkan peninsula. Retiring from the foreign office, he retained the imperial chancellorship, which he had held since 1845.

Nesselrode died in St. Petersburg on March 23 (new style; 11, old style), 1862. A German translation of his autobiography (the original manuscript is in French) appeared in 1866; and 11 volumes of selections from his letters and papers (also in French) were published in 1904–12. (G. A. Ln.)

NEST. The practice of nest building (nidification), as the term is used in zoology, includes all preparations for the reception of eggs or newborn young and for their care. Common conceptions of nest making are derived from observations of birds; but mammals, reptiles, amphibians and fishes, as well as invertebrates, include species that make more or less elaborate preparation in advance for the reception of their young. The first stage in this sequence is the selection of a definite site for the nest, in or on which the eggs or young are to be deposited. Two chief factors governing this preparation are the conditions of the environment and the state of the young on emergence.

BIRDS

Not all birds make nests; some waterfowl and a few land birds lay eggs on bare rock or ground. For example, auks and murres deposit single eggs on bare ledges of rock projecting from the face of a cliff rising steeply from the sea. Species that haunt sandy wastes make little or no preparation by way of a nest. This receptacle seems originally to have been an adaptation for the purpose of keeping the incubating bird and the eggs from contact with cold, damp earth.

Much more elaborate are the nests of the smaller species. These, placed in hedgerows or bushes or even on the ground, are bowl-shaped structures made of fine grass interwoven with horsehair and cunningly masked by moss or lichen, as in the case of the European long-tailed titmouse. Some, like the thrush, use a foundation of clay and line the interior of the nest with a mixture of decayed wood and cow dung. Certain African weaverbirds and American Baltimore orioles or hangnests, suspend the nest (made of long grass stems and vegetable fibres) by a long fibrous strand or rope attached to the bough of a tree. Toward the end this rope is enlarged to form a spherical chamber, with an entrance at the top or side in the hangnests; and at the end of a further extension of the rope beneath the nest in the weavers. Some of the flowerpeckers of Australia build a nest of felted cotton down. A few species make a more or less extensive use of saliva as a cement for mud-built nests, as the swallow tribe, the South American ovenbird and the flamingo. The use of salivary glands in nest building reaches its maximum with the swifts which glue small twigs to the inside of a chimney to form a tiny basket or, as in the case of the Asiatic edible swifts, use saliva alone. Such nests are harvested early in the nest-building season and used by the Chinese in making bird's nest soup.

Hollows in trees are used by many birds, such as the parrots and the woodpeckers, the eggs being deposited on the rotten wood at the bottom of the hole. Others, like the bank swallow (sand martin) and the kingfisher, drive long tunnels into the face of a sandbank, enlarging the end of the tunnel to form a nest chamber. The greatness of this achievement is commonly overlooked, for it would be difficult to find birds so unsuited for such a task. The sand martin has very feeble feet and an extremely short beak, while the short legs, partly united toes and long pointed beak of the kingfisher seem less fitted for burrowing.

While there is general conformity of type characteristic of the nests of the different groups of birds, there are striking exceptions to the rule. The stork tribe, generally, is content with a simple platform of sticks; but the hammerhead stork (*Scopus umbretta*) builds a huge nest of mud and sticks, covered over by a roof that may be as much as six feet across and so substantial as to bear easily the weight of a man. The flamingos build a steep pedestal of mud, the top of which is scooped out to receive the eggs. Parrots nest in hollow trees, but the quaker-parrot (*Myopsittacus*) of South America builds a large domed nest of sticks.

The chickenlike or gallinaceous birds make little more than a shallow depression in the ground. The fowllike megapodes of Celebes, New Guinea and Australia, however, build a huge mound of decaying vegetable matter, lay their eggs deep down in the fermenting mass and leave them to hatch by the heat generated by decay.

One of the most remarkable cases of nest building among birds is furnished by the hornbills, whose eggs are laid at the bottom of a cavity in a tree. As soon as the female has started incubation the male closes the entrance hole with clay; he leaves open a space only wide enough for his mate to push her beak through to receive food from him. *See* also Bird.

OTHER NEST BUILDERS

Mammals.—Few other animals are as skilful as birds in weaving nests. The harvest mouse among the mammals is, however, the rival of most birds, and many squirrels build bulky structures in treetops or vines. The rabbit builds a nest in her burrow and lines it with the underfur plucked from her body in the same manner as ducks, geese and swans line the nest with down plucked from the breast. The only nest-building mammals that produce eggs are the echidna or spiny anteater *Tachyglossus* and the duck-billed platypus *Ornithorhynchus*. The nest is of the simplest character, a chamber lined with leaves and grass at the end of a long tunnel dug by the animal.

Reptiles.—Among the reptiles nest building, if practised, goes little further than digging a hole in the ground and depositing the eggs within it, leaving them to their fate. The European pond tortoise, however, takes a little more trouble. She prepares the ground by watering it from the bladder and from special anal water sacs. Then, boring a hole with the tail, as one would use a stick, the tortoise enlarges it with her feet. When the hole is about 5 in. deep the eggs are laid at the bottom, the soil is replaced and beaten down flat. The crocodile digs a hole in the sand about 2 ft. deep, lays her eggs in it and covers them. She returns periodically to sleep above the incubating eggs and is thus at hand to assist the young to escape at the time of hatching. She is warned of this by the noise they make in endeavouring to break through the shell, just as young birds announce their advent by cheeping before the shell is actually broken. When the baby crocodiles have all emerged the mother escorts them to the water. The alligator, on the other hand, builds a great mound of decaying vegetation in a marsh to a height of about 3 ft. and as much as 8 ft. in diameter. The white and hard-shelled eggs, 20 to 30 of them, are laid about 8 in. from the surface.

The python, among the snakes, like *Ichthyophis* among the Amphibia, coils her body around the eggs until they hatch and guards her young for some time after.

Amphibians.—Among amphibians, frogs of the genus *Phyllomedusa* build nests resembling those of the tailorbird. *Phyllomedusa hypochondria*, the *Wollenkukk* of the Paraguayan Chaco is a good example. The female carries the male upon her back while searching for a suitable leaf, which must be on a tree overhanging the water. This found, both seize it and hold the edges together with their hindfeet; the female pours her eggs into the

funnel thus formed while the male fertilizes them as they pass in. The gelatinous envelope of the eggs suffices to hold the leaf edges in position as they are brought together in the filling process, which goes on until about 100 eggs are laid.

Fishes.—Among the fishes the freshwater sticklebacks (*Gasterosteus*) and the marine 15-spine stickleback (*Spinachia*) build nests of weeds, the task being undertaken by the male, who uses a secretion produced by the kidneys as a binding material. He has sole charge of the eggs and young. The gourami (*Osphronemus*) of the Malay archipelago fashions a nest of air bubbles toughened by a kind of saliva, and mounts guard over both eggs and young. The perchlike fishes of the family Cichlidae, both of America and the old world, as well as some of the catfishes and their relatives (siluroid fishes), carry the young in the mouth; in some species both sexes do this, in others the male alone. The male pipefish and seahorse carries the eggs and young either in a pouch running along the belly or attached to his body. The aspredo, a catfish of the Guianas, carries her eggs attached to the under surface of the head, belly and paired fins. The skin assumes a spongy condition for their accommodation so that each lies within a depression, recalling the egg pits of the Surinam toad; in the case of aspredo, however, the pits are shallower and the larvae are not retained there.

Invertebrates.—Among the insects the elaborate care for the eggs and young displayed by the ants, bees and wasps is well known (*see* SOCIAL INSECTS). The scorpions and the wolf spiders carry their young on their backs until they can fend for themselves; some of the scorpions, again, like the wolf spiders, carry their eggs closely packed within a spherical silken bag.

Among the marine invertebrates an antarctic sea slug (*Cucumaria crocea*) carries the young on its back. One of the sea urchins (*Hemiaster philippi*) and a starfish (*Asterias spirabilis*) carry the young in brood pouches—on the back in the case of the sea urchin and around the mouth in the starfish. It would seem that only arctic and antarctic species behave in this manner. In all other cases the young leave the parent as minute, free-swimming larvae and undergo a complicated metamorphosis before they become fully grown.

In the invertebrates the care of the young must be regarded as an entirely impersonal, unconscious act, determined by the physical peculiarities of the external environment. This should be borne in mind in considering the origin and evolution of nest building in animals of all levels.

NESTOR (11th–12th century), Russian hagiographer and chronicler, was a monk of the Monastery of the Caves in Kiev. He was received into the monastery in or soon after 1074, and is thought to have been still alive in 1113. He wrote the lives of SS. Boris and Gleb, the sons of St. Vladimir of Russia, who were murdered in 1015, and the life of St. Theodosius, abbot of the Monastery of the Caves (d. 1074). A tradition first recorded in the 13th century ascribes to him the authorship of the *Povest Vremennykh Let* (*Russian Primary Chronicle*), the most important historical work of early medieval Russia. Modern scholarship, which regards the *Chronicle* as a composite work, written and revised in several stages, inclines to the view that Nestor, about 1113, compiled the basic, though not the final, version of this document. The *Chronicle*, extant in several medieval manuscripts, the earliest dated 1377, was compiled in Kiev. It relates in detail the earliest history of the Russian people down to the second decade of the 12th century. Emphasis is laid on the foundation of the Kievan state, ascribed to the advent of Varangians from Scandinavia in the second half of the 9th century, the subsequent wars and treaties between the Russians and Byzantium, the conversion of Russia to Christianity *c.* 988, the cultural achievements of the reign of Yaroslav of Kiev (1019–54) and the wars against the Turkic nomads of the steppe.

Written partly in Old Church Slavonic, partly in the Old Russian language based on the spoken vernacular, the *Chronicle* includes material from translated Byzantine chronicles, west and south Slavonic literary sources, official documents and oral sagas. This borrowed material is woven with considerable skill into the historical narrative, which is enlivened by the powers of vivid description, the humour and the sense of the dramatic displayed by the different compilers and is given added depth of perspective by their appreciation of the position occupied by the land of Russia within the Christian community of nations.

See edition of *Povest Vremennykh Let* with Russian trans. and notes by V. P. Adrianova-Peretts, 2 vol. (1950); Eng. trans. with notes by S. H. Cross and O. P. Sherbowitz-Wetzor (1953). (D. OB.)

NESTOR, in Greek legend, son of Neleus and Chloris, king of Pylos (Navarino) in Elis. When all his brothers were slain by Heracles, in consequence of the refusal of Neleus to purify him for the murder of Iphitus, Nestor alone escaped. In the *Iliad* he is about 70 years old, having seen two generations of men flower and die. Sage and pious, his role is largely to incite the warriors to battle and to tell stories of his early exploits, by contrast with which his auditors' warlike experiences are shown to be soft and easy. After the war Nestor returned easily to Greece, avoiding the troubles and wanderings which afflicted Agamemnon, Menelaus and Odysseus (*qq.v.*). In the *Odyssey*, whose dramatic date is ten years later than that of the *Iliad*, Nestor is still ruling in Pylos, where he is visited by Telemachus. Ovid parodied his antique garrulity, making him 200 years old and putting into his mouth a long and gruesome account of the famous battle between the Lapithae and the Centaurs (*Metamorphoses*, 12). (T. V. B.)

NESTORIANS, historically, were those Christians of Asia Minor and Syria who refused to accept the condemnation of Nestorius and his teachings by the Council of Ephesus (431). In modern times they are represented by the CHURCH OF THE EAST, usually referred to in the west as the Assyrian or Nestorian Church. Most of its members—numbering perhaps 100,000—live in Iraq, Syria and Iran. There are about 3,000 in the United States. The catholicos-patriarch, Mar Eshai Shimun XXI (b. 1909), who was exiled from Iraq in 1940, resides in San Francisco.

The liturgical language of the church is Syriac. There is a variety of rites. In the communion service three different anaphorae are used: of Addai and Mari, of Theodore of Mopsuestia, and of Nestorius.

Origins and Early History.—The condemnation of Nestorius (*q.v.*) and his teaching by the ecumenical Council of Ephesus was strongly resented in the churches of Asia Minor and Syria. Though these churches finally accepted the decision of the council, there remained a considerable minority unwilling to conform. The centre of resistance was the renowned theological school of Edessa (*q.v.*) in eastern Syria (modern Urfa, Turk.), a school rigorously adhering to the Antiochene tradition as represented by Nestorius. Theodore of Mopsuestia, "the Interpreter," was regarded there as the main authority in all matters of faith. As early as 457 some teachers were compelled to leave the school, moving across the border into Persia. The Edessa school was closed by imperial order in 489, and a small but vigorous Nestorian remnant migrated to Persia.

The Christian church in Persia was by that time a comparatively large body, but its connection with the churches in the west, within the limits of the Roman empire, had always been loose, although it was represented at the first ecumenical council (Nicaea, 325). The full independence of the church in Persia was formally proclaimed by local councils held at Seleucia in 410 and at Markabta in 424. The bishop of Seleucia-Ctesiphon (the capital of the Sassanid kingdom) was acknowledged as the supreme head of the church in the realm—"the great metropolitan and the head of all bishops." The primary reason for this declaration of independence seems to have been political: relations between Persia and the Roman empire were strained and inimical, and administrative links with the foreign churches would expose the church to suspicion on the part of the government. There was also a national motive: the church in Persia was Syriac-speaking, only slightly touched by Greek culture. On the other hand, it was theologically dependent upon the school of Edessa, commonly known as "the school of the Persians."

Under pressure from Barsauma (Barsumas), a refugee from

Edessa and bishop of Nisibis (Nisibin), the council of the Persian church at Beth Lapat (or Jundishapur), in 484, acknowledged Theodore (*q.v.*) of Mopsuestia as the guardian of right faith. Accordingly, the teaching of the Western churches was censured as erroneous. After several years of internal struggle, the allegiance to Theodore was reconfirmed once more under the patriarch Babai (497–502). Since that time the Christian church in Persia has been Nestorian. This name of course was never officially used—it was a discriminatory label, invented by enemies (probably the Monophysites). The official name, still retained, is simply "the Church of the East."

Christians have always been a minority in Persia, and the church went through a period of troubles and persecutions. But finally it was recognized as a kind of national minority and, as such, obtained legal status. By the end of the 5th century there were seven metropolitan provinces in Persia proper and several bishoprics abroad—in Arabia (especially in the state of Hira) and in India. The church's intellectual centre was the new school in Nisibin, which carried on the venerable traditions of Edessa. It was at once a school and a community under rigid discipline; its statutes (496) are preserved. The program was restricted to the study of theology, primarily of the Bible. Theodore was regarded as the chief authority, and his exegetical writings were closely followed. Greek learning was disavowed, though Aristotelian logic was admitted; indeed the main logical treatises of Aristotle, together with Porphyry's famous "Introduction," had been translated into Syriac at Edessa, by Bishop Ibas. It was primarily through Syriac translations that the Arabs became acquainted with Greek thought. In the course of time, other schools of the same type were established in the country.

The church was greatly strengthened by the wise leadership of the patriarch Mar Aba I (in office 540–552), a convert from Zoroastrianism, an able scholar and efficient ruler, and also by the renewal of monasticism, on the Egyptian pattern, guided by Abraham of Kaskar (491/2–586), the founder or restorer of the monastery on Mt. Izala, near Nisibin. Another great leader was Mar Babai the Great (569–628), a monk of Mt. Izala, who was in charge of the vacant patriarchate in the troubled years of the reign of Khosrau II and his struggle with Byzantium.

Babai was a scholar, and his treatise on Christology, *The Book of Union*, is still regarded as an authoritative exposition of doctrine in the Church of the East. On the whole, the doctrine was gradually stiffened, in opposition to the growing spread of Monophysitism and, indeed, in response to the formal condemnation of Theodore and Ibas by the fifth ecumenical council (553) (*see* COUNCIL: *Second Council of Constantinople* [553]). Moreover, there was defection within the church itself. Hanana, head of the Nisibin school in 572–610, advocated the acceptance of the Council of Chalcedon and actually replaced Theodore with St. John Chrysostom in the field of exegesis. Though he was strongly censured he continued in the school till his death.

From the Arab Conquest to the Mongol Invasion.—The Arab conquest of Persia, completed by 651, did not change the legal status of the church there. In spite of certain restrictions, the church in the caliphate was recognized as a separate national group and was granted legal protection. Nestorian scholars played a prominent role in the formation of Arab culture, and the patriarchs occasionally gained influence with the rulers. After the foundation of the new capital, Baghdad (762), under the Abbasid dynasty, the residence of the patriarch was transferred there.

For more than three centuries the Church of the East prospered under the caliphate, and some modern scholars have suggested that this very prosperity was the main reason for its ultimate decline. The church became worldly and its standards were lowered. It lost leadership in the cultural life. Externally, however, it expanded greatly. By the end of the 10th century there were 15 metropolitan provinces in the caliphate itself and 5 beyond the border, including those as far away as India and China. Nestorians spread also to Egypt, where Christianity was under Monophysite control. Nestorian missions were an important move, but they represented rather a spreading, with the shift and migration of population, than an organized propagation of faith. In many places Christian communities retained their foreign character and were not integrated into the native life. In many cases Christianization was superficial. Western travelers of the 13th century speak of the ignorance and superstition of Nestorian clergy in the Mongol empire. In China there was a considerable Nestorian Christian community in the 8th century, but it did not survive the fall of the T'ang dynasty in the early 10th. The spread of Christianity in central Asia was of another character. Certain Tatar tribes were almost entirely converted to Nestorian Christianity, Christian expansion reaching almost to Lake Baikal.

The Mongol invasion of Asia did not destroy the church. Prior to their conversion to Islam, the Mongols were tolerant in religion, and western travelers to the Mongol realm found Christians well established there, even at the court of the Great Khan. The conquest of Baghdad (1258) by Hulagu did not affect the Church of the East. It is uncertain whether Hulagu himself was a baptized Christian, but his wife certainly was, and the Mongol dynasty of the Il-khans in Persia was closely allied with the Christian kingdoms of Armenia and Georgia. Kublai Khan was favourably disposed toward Christians.

But the situation was ambiguous. The Mongol attitude was controlled by political calculations: they had to choose between Islam and the Christian west. The victory of Islam and the collapse of the crusades by the end of the 13th century led finally to their adoption of Islam, and the fate of Christianity in the east was decided. The Church of the East was reduced in size and numbers, and during the 14th century its defeat was sealed by the raids of Tamerlane. Nestorian communities lingered on in a few towns of Mesopotamia, but were concentrated mainly in Kurdistan, in the area between the Tigris and Lakes Van and Urmia, partly in Turkey and partly in Persia.

Modern Times.—The church was split in 1551, and one group went over to Rome. Since that time the Nestorian group has been denoted as Assyrian, while the Uniate group is commonly described as Chaldean (*see* ROMAN CATHOLIC CHURCH: *Organization: The Catholic Eastern Rites*). The Nestorian church in India allied itself with Rome (1599), then split, half its membership transferring allegiance to the Syrian Orthodox (Monophysite) patriarch of Antioch (1653) (*see* MALABAR CHRISTIANS).

In the 19th century the tiny Nestorian remnant in Kurdistan was rediscovered by western Protestants, who were eager to counteract the influence of the Roman Catholic missions in the area and also to raise the cultural level of the neglected Christian group. It seemed that this was the oldest church in Christendom still using the original language of the Gospels (Syriac = Aramaic). Both British and American societies were at work. The "Archbishop of Canterbury's Assyrian Mission" began its activities in 1881, the purpose being to reform or to renew the church from within. The question of formal intercommunion with the Anglican Church was raised in 1912. The work of the Presbyterian mission of the United States led to the formation of the Syrian Evangelical Church in Iran, now called the Evangelical Church of Iran. A considerable group of Nestorians in northern Iran, led by bishop Mar Yonan (Jonas) of Supurghan and Urmia, was reunited with the Orthodox Church in Russia (1898), and a Russian missionary centre was established in Urmia.

The Assyrians suffered heavy losses during World War I through massacre, disease and exposure. It is estimated that up to one-third of the nation perished at that period. A considerable group migrated to Mesopotamia and others left for the United States. There is still a group resident in Iran. For political reasons the patriarch of the Assyrians was compelled to leave for England and later for the United States.

(G. V. F.)

NESTORIUS (d. *c.* 451), patriarch of Constantinople and heresiarch, was born (exact date unknown) and spent his early years at Germanicia in Syria Euphratensis (present-day Maras in southern Turkey). He studied at Antioch, probably as the pupil of Theodore of Mopsuestia, and imbibed the principles of the famous theological school there. He became a monk at the nearby Euprepius monastery and, after being ordained priest, acquired a great reputation for asceticism, orthodoxy and eloquence. Mainly because of this Theodosius II nominated him to the see of Constantinople in 428. His debut was a stormy one, for he immediately set to work extirpating heretics of every sort, showing leniency only to Pelagians. A crisis, however, developed when his chaplain, Anastasius, denounced the practice of giving the Blessed Virgin the title *Theotokos* ("God-bearer"), and Nestorius, who had already expressed doubts on the subject, rushed to his support. Orthodox theologians had long used the title, which the growing cult of the Virgin made highly popular; but Nestorius considered that, unless carefully qualified, it compromised Christ's full humanity.

In the controversy which flared up Nestorius' opponents found an ally in Cyril of Alexandria, who, much more alive to the political issues, was only too eager to make capital for his own see (*see* CYRIL, SAINT). Both sides appealed to Pope Celestine I, whom Nestorius' tactlessness had already alienated, and in Aug. 430 a Roman synod decided that correct Christology required the use of *Theotokos* and requested Nestorius to disown his errors. When Cyril, who had been charged to execute the sentence, produced a string of provocative anathemas for him to subscribe, Nestorius and his Antiochene-minded friends took alarm, and he persuaded the emperor to convene a general council. When it met, however, at Ephesus in June 431, he found himself hopelessly outmaneuvered by Cyril (*see* COUNCIL: *Council of Ephesus* [*431*]). His teaching was condemned and he himself deposed from his see. Theodosius was induced to ratify these decisions, and Nestorius after languishing in his old monastery near Antioch was exiled in 436 to Upper Egypt, where he died, protesting his orthodoxy, *c.* 451. Apart from his apologetic *Book of Heracleides*, a Syriac version of which came to light *c.* 1895, only fragments of his sermons and letters survive. A Syriac anaphora bearing his name is probably inauthentic.

Nestorianism.—Nestorius is reckoned one of the principal heretics in Christology, and the heresy traditionally linked with his name, Nestorianism, was formally condemned at the Councils of Ephesus (431) and Chalcedon (451). Whereas orthodox Christology holds that Christ incarnate has two natures, divine and human, ineffably united in one person or hypostasis (the "hypostatic union"), Nestorianism so stresses their independence as to suggest that they are in effect two persons or hypostases loosely joined by a moral union. It envisages the divine Word as having associated with himself at the incarnation a complete, independently existing man, and thus approximates to adoptionism (*q.v.*). From the orthodox point of view it therefore denies the reality of the incarnation, representing Christ as a God-inspired man rather than as God-made-man. Hence Cyril (*Anathema* iii, viii) could condemn anyone who "divides the hypostases after the union . . . connecting them by a mere association in dignity or authority or rule, and not rather by a conjunction of real union," or who asserts that "the man assumed" (*i.e.*, the human nature) is to be co-worshiped along with God the Word, instead of the Word-made-flesh being adored with a single, indivisible worship; while the Chalcedonian definition outlawed "those who presume to rend the mystery of the incarnation into a duality of Sons." Since the 5th century all the principal branches of the Christian church have united in condemning Nestorianism as thus defined, affirming that Christ is a single person, at once wholly human and wholly divine. Even the so-called Nestorian church (*see* NESTORIANS) is not Nestorian in the strict sense, although it venerates Nestorius' name and refuses to accept the title *Theotokos*.

Nestorius' Own Teaching.—It is questionable whether Nestorius himself ever taught, or intended to teach, the heresy named after him. Admittedly he gave colour to his opponents' accusations by his habit of speaking of Christ's natures as "the God" and "the man" or "him who assumed" and "him who was assumed" respectively, by insisting on a loose, voluntary union between them defined as *synapheia* ("conjunction") rather than *henosis* ("union"), and by his suspicious attitude, illustrated by his critique of the *Theotokos*, toward the *communicatio idiomatum*, *i.e.*, the convention by which, in view of the absolute oneness of Christ's person, the attributes, experiences, etc., of each of his natures could properly be predicated of the other. The fact remains, however, that he was convinced of, and repeatedly affirmed, the perfect unity of the incarnate Lord, repudiated any suggestion of there being two persons or two Sons existing side by side in his being, and scornfully rejected the charge of being virtually an adoptionist.

His authentic teaching, it would seem, though expounded in crudely provocative terms, showed little difference from, or advance on, that of his great predecessors in the Antiochene school, Diodore of Tarsus and Theodore of Mopsuestia, who had been admired as orthodox in their lifetime. Like theirs, his Christology was of the "Word-man" type rather than the "Word-flesh" type accepted in the Alexandrian school and sponsored in particular by Cyril. Whereas the latter started with the idea of the eternal Word who at the incarnation became "enfleshed," the former tended to hold the divine and human natures apart, emphasizing their completeness and independence, and thus was faced with the difficult problem of explaining their union. The motive for this distinctive approach was twofold: to safeguard the impassibility of the Word, and to ensure in the interests of sound soteriology that Christ should have lived a genuinely human life of growth, temptation and suffering. In particular the Antiochenes rejected the Alexandrian view that the Lord's humanity was vivified by its union with the Word, with the result that in the field of eucharistic doctrine Nestorius was unfairly charged by Cyril with teaching cannibalism, since the sacramental body consumed by the faithful was according to him the body of a mere man.

Nestorius' own original contribution was the suggestion that, each nature subsisting in its own *prosopon* (*i.e.*, external, undivided presentation), there was at the incarnation a mutual exchange of *prosopa* resulting in the emergence of a common *prosopon*. Thus "*prosopon* of union," by which he in effect understood the historical figure of the Gospels, was identical with neither the *prosopon* of the Word nor the *prosopon* of the humanity but resulted from the coming together of the two.

Modern estimates of Nestorius' teaching differ widely, some applauding its honest attempt to do justice to the reality of Christ's humanity and incarnate life, others condemning it either for its internal difficulties or, more radically, for failing to recognize that the subject of the God-man must be the divine Word and for thus opening a door to Nestorianism proper. There can be no doubt, however, that it was far removed from the latter in intention at any rate. Nestorius was the victim at once of his own intolerant temperament and of the rivalries between great sees which was a feature of the times. It was ironical that very

soon after his condemnation several important elements in his doctrine, such as the conception of two natures itself, came to be recognized as indispensable to sound Christology and were incorporated in the Chalcedonian definition.

NESTROY, JOHANN NEPOMUK EDUARD AMBROSIUS (1801–1862), Austria's greatest comic dramatist and a brilliant character actor who dominated the Viennese popular stage in the mid-19th century, was born at Vienna on Dec. 7, 1801. He made his debut as an opera singer in Vienna in 1822 and from 1823 to 1831 had engagements in Amsterdam, Brünn, Graz and Pressburg, gradually abandoning operatic for dramatic roles. In 1831 he returned to Vienna and became the leading character actor and comic dramatist of his day. From 1854 until his retirement in 1860 he managed the Carl-Theater. He died at Graz on May 25, 1862.

Nestroy represents the last phase of the Viennese popular drama which originated in the 17th century. In his comedies the pathos and humour of his contemporary F. Raimund are replaced by satire, irony and parody (C. F. Hebbel and Richard Wagner were among his victims) and by a realistic portrayal of Viennese types and manners. His plays abound in memorable aphorisms. *Der böse Geist Lumpazivagabundus* (1833), *Die beiden Nachtwandler* (1836), *Das Mädl aus der Vorstadt* (1841) and *Einen Jux will er sich machen* (1842) are typical examples of his work.

Fischer, "J. Nestroy," in *Sinn und Form*, xiv, 3 (1962). (C. P. Mag.)

NET, a fabric of thread, cord or wire, the intersections of which are looped or knotted so as to form a mesh. Netting, intimately related to weaving, knitting, plaiting and lacemaking, is one of the most ancient and universal of arts.

Primitive Nets.—Widespread distribution among primitive peoples of the main types of net supports the belief that netting was one of man's first inventions. The early stages in the manufacture and use of nets are difficult to trace because materials were perishable and tools simple; but there is strong evidence that nets were employed in southern Europe from upper Paleolithic times to answer the needs of a hunting, fishing and food-gathering economy. The oldest known piece of netting in Europe was found near Korpilahti, Finland, in 1914. It was part of a knotted seine net (*see* below) made from twined threads of plant bast and used by Mesolithic fishermen. An example of the oldest basic form of knotless net, consisting of simple loops, was discovered at a Neolithic site in Schötz, Switz., and a more complex loop-and-twist net of the same period was recovered from the bog of Ordrup, Denmark. In Australia the geographical distribution of net types among the aborigines suggests that knotted nets may have come before knotless. But netting appears to have remained completely unknown in southwest Australia and in Tasmania.

Primitive netting was fabricated with thread or cord made from a wide range of vegetable fibres (*e.g.*, bark, bast, cotton, coconut, leaves, roots, stems) and animal tissues (*e.g.*, hide, sinew, hair, intestine, baleen). Needles and mesh gauges for netmaking were of wood, bone, ivory, antler and shell.

Many specialized forms of netting were developed for articles such as hammocks and snowshoe lacings; but, apart from carrying nets, the most important nets are those for hunting and fishing. Lines of land nets were early adopted to capture animals driven into them by beaters. Primitive fishermen evolved numerous varieties of nets suited to the conditions of river, estuary, shore or open sea. These varieties may be described as self-acting, *i.e.*, stationary nets fixed so as to entangle fish in their meshes or trap them in chambers; and manipulated, *i.e.*, nets handled by one or more persons. This second group embraces framed or unframed hand nets, seine nets with floats and sinkers, weighted cast nets and trawl nets. (D. M. Bo.)

Modern Nets are made both from vegetable fibres (*e.g.*, cotton, hemp, flax, manila, sisal) and from man-made fibres (*e.g.*, nylon, polyester, polypropylene and polyethylene). The man-made fibres are inherently rotproof whereas the vegetable fibres have to be treated against rot with substances such as tar. Three types of net, all with diamond-shaped mesh, are used for fishing: gill nets, seine nets and trap nets.

Gill nets, sometimes called drift nets, entrap fish by their gills. A variant, the trammel net, composed of two outer panels of large-mesh netting enclosing an inner panel of smaller mesh netting, entangles the fish in pockets formed by the passing of the inner net through the mesh of the outer net or "wall." The size of the fish trapped depends on the coarseness or fineness of the meshing. Gill nets can be used at the surface, at mid-water or at the bottom of the water (salt or fresh) according to the adjustment of floats at the top and of lead sinkers at the bottom of the net.

Seine nets are large nets used for enclosing schools of fish and are sufficiently fine meshed not to entangle them by the gills. Some, called beach seines, can be hauled onto the beach with their contents; others, called purse seines, are operated from boats in deep water far from shore. The two ends of the net are hauled aboard the boat and the catch is secured by closing the bottom of the net with a rope called a purse-seine line. Seine nets are always operated at the surface and are fitted with floats at their upper edge to ensure buoyancy and with leads or chain at the bottom so that they hang in the water to maximum depth. They catch sardines, herring, pilchards, salmon, tuna, etc., and can enclose at one time schools of fish weighing up to 100,000 lb. They are called ring nets in Scotland and are there sometimes operated by two boats. Variants of the seine are the trawl net, the Danish seine and the wing or vinge trawl. These are dragged along the seabed, from which they scoop up, for example, cod, haddock, plaice and sole.

Trap nets, staked to the shore or in estuaries, form a labyrinth-like chamber into which fish swim. The mesh must be fine enough to prevent the escape of fish of marketable size and coarse enough to allow unmarketable fish to swim through

Salmon, trout and eels are their principal catch. A floating trap net, used especially in North America, has buoys and anchors instead of stakes. Eel traps and lobster traps, consisting of a framework covered with netting, are also forms of trap net.

Nets used for purposes other than fishing are made of the same materials but are often square meshed, especially those used for sports, *e.g.*, tennis nets, cricket practice nets and goal nets. Netting is used in horticulture for supporting peas and beans, for protecting crops from birds and frost and for the bags in which produce is marketed; in industry as safety netting for workers; in transport for securing loads on vehicles, hoisting cargoes aboard ship and for parcel racks on trains and aircraft. Netting made from wire differs from netting made from fibres in that the wires are twisted at the intersections and not knotted.

Manufacture.—Net is still made (in small quantities) by the ancient method of forked needle and mesh pin, but most commercial production is machine manufactured. A netting machine was patented in England in 1778 by William Horton, William Ross, Thomas Davies and John Golby. An early 19th-century incomplete French model by Joseph Jacquard is in the Conservatoire des Arts et Métiers, Paris. The first machine efficient enough to commence a new netmaking industry was designed by James Paterson of Musselburgh, Scot., who established a net factory there about 1820, but his early form of machine was imperfect, the knots it formed slipped readily and, there being much prejudice against machine nets, the demand for his products was small. In 1835 Walter Ritchie, also a native of Musselburgh, patented a machine involving a method of forming the ordinary hand knot; and this became the foundation of an extensive and flourishing industry. Another form of net loom was invented and patented in France by Onésiphore Pecqueur in 1840; and again in France and in Great Britain in 1849. This was subsequently often improved, principally by Baudouin and Jouannin. In the United States a manufacturer of cotton yarns at Canton, Mass., initiated net manufacture for the fisheries about 1844; and the success of his experiments in cotton twine resulted in the first netting machine in the United States starting production in 1858 and the later development of improved models for handling heavy twines. Modern netting machines are manufactured in the United States, the United Kingdom, Finland, France and Japan. Improvements make it possible to manufacture nets with double knots as well as with single knots; double knotting is often desirable because of the slipperiness of man-made fibres.

NETBALL, a popular game in English girls' schools, is similar to girls' basketball in the U.S. (*see* BASKETBALL: *Women's Basketball*). It is played on a hard-surfaced rectangular outdoor court measuring 100 ft. by 50 ft. with half circles 16 ft. in radius marked at either end for shooting. The goal posts stand 10 ft. high with circular rings, or baskets, and nets at the top for the ball to pass through. The ball is usually of leather, about 27 in. in circumference and weighs 14 to 16 oz.

The game is played between two teams of seven players each—three centre players, two attacks and two defenses. The ball must be passed hand to hand from player to player and no one may run with it. The centre players try to pass the ball up the court into the circle for the attackers to shoot. The defenders, by guarding their opponents and by intercepting, try to prevent goals from being scored.

The game is played for 15 or 20 min. each way with a 5-min. break at half-time. (C. T. E.)

The game called netball in the United States is similar to volleyball (*q.v.*) except that the ball is thrown and caught instead of being batted. The player may not walk with the ball, which must be thrown from the place where it is caught. The penalty is loss of serve if the foul is committed by the serving side or one point to the serving side if committed by the receiving side. As in volleyball, a game may be played on a time instead of a point basis. (M. D. HA.)

NETHERLANDIC LANGUAGE. Netherlandic is the national language of Holland (kingdom of the Netherlands) and one of the two national languages (besides French) of Belgium. Popular English usage applies the term "Dutch" to the Netherlandic of Holland and "Flemish" to the Netherlandic of Belgium, but in actual fact they are the same language. In its various forms, standard and dialectal, Netherlandic is the indigenous language of most of Holland (all but the Frisian-speaking province of Friesland), of northern Belgium and of a small part of France immediately to the west of Belgium. Netherlandic is also used as the language of administration in the colonies of Holland, and a derivative of it (with slightly different sounds, simplified grammar, but similar vocabulary) is the Afrikaans spoken besides English in the Republic of South Africa.

As a written language, Netherlandic is quite uniform; it differs in Holland and Belgium no more than written English does in the United States and Great Britain. As a spoken language, however, it exists in far more varieties than does the English of North America. At one extreme is Standard Netherlandic (*Algemeen Beschaafd Nederlands* "General Cultured Netherlandic"), which is used for public and official purposes and is the language of instruction in schools and universities. It is everywhere quite uniform, except that speakers usually show by their accent the general area from which they come. At the other extreme are the local dialects, used among family and friends and with others from the same village. Some dialects are very similar to the standard language, while others are markedly different from it.

Sounds and Spelling.—Netherlandic has three classes of vowels and diphthongs: (1) six checked vowels, which are short and occur only before consonants; (2) thirteen free vowels, most of them long, which can occur in all positions (though three are found only in foreign words); and (3) a vowel that occurs only in unstressed position.

Usual spelling						Phonetic value					
			ie	uu	oe				i	y	u
i	u	o	ee	eu	oo	e	ø	o	e:	ø:	o:
			ij,ei	ui	ou				ei	œy	ɔu
e		o				ɛ		ɔ			
			(e	eu	o)				(ɛ:	œ:	ɔ:)
a				aa		ɑ				a:	
Unstressed: e						Unstressed: ə					

Examples of the checked vowels: *bit* "bit," *put* "well," *bot* [bot] "flounder," *bed* "bed," *bod* [bɔt] "offer," *bad* "bath." Many speakers have no contrast between [o] and [ɔ], but generally use [o] before nasals (*bom* "bomb"), [ɔ] elsewhere (*bot, bod*). The free vowels spelled *ie, uu, oe* are long only before *r: bier* "beer," *buur* "neighbour," *boer* "farmer"; short otherwise: *biet* "beet," *buut* "goal," *boet* "mends." The other free vowels and diphthongs are long: *beet* "bite," *beuk* "birch," *boot* "boat," *bijt* "bites," *buit* "booty," *bout* "bolt," *baat* "benefit"; and, in foreign words, *scène* "scene," *freule* "young lady of noble birth," *zone* "zone." When the free vowels *uu, ee, oo, aa* occur in an open syllable (before a single consonant plus another vowel), they are written singly: *buur, beet, boot, baat* (as above), but plural *buren, beten, boten, baten.* When the checked vowels occur in an open syllable, the following consonant letter is doubled: *bit, put, bot* (as above), but plural *bitten, putten, botten.*

Standard Netherlandic has the following system of consonants:

stops	p		b	t		d		k			*other:*	l	r
spirants	f		v	s		z	ch		g	h		w	j
nasals		m			n			ng					

p, t, k are unaspirated; *ch, g, ng* are phonetically [x], [ɣ], [ŋ]; *r* is uvular with some speakers, apical with others. After vowels *w* is a bilabial semivowel, but initially or after consonants it is a fully voiced labiodental spirant; it contrasts with the weakly voiced labiodental *v*. *j* is like English *y*.

Of the stops and spirants, *p, t, f, s, ch* are fortis and voiceless, while *b, d, v, z, g* are lenis and weakly voiced. *k* is usually fortis and *h* usually lenis; but *see* below. The contrast between lenis and fortis is suspended before pause, where only fortis stops and spirants occur. The spelling shows this in the case of *v* and *z: geven, lezen* "give, read," but *ik geef, ik lees* "I give, I read"; it does not show it in the case of *b, d, g: hebben, redden, leggen* "have, save, lay," but *ik heb, ik red, ik leg* "I have, I save, I lay," pronounced *hep, ret, lech*. In normal transition, fortis stops and spirants become lenis before a following *b* or *d: dat boek* "that book," pronounced *dad boek; vijf dagen* "five days," pronounced *vijv dagen; poetsdoek* "polishing cloth," pronounced *poedzdoek;* and similarly, *ik ben* "I am," with lenis *k*. On the other hand, lenis spirants become fortis after any preceding fortis stop or spirant: *het vuur* "the fire," pronounced *het fuur; op zee* "at sea," pronounced *op see; vijf ganzen* "five geese," pronounced *vijf chanzen;* and similarly, *vijf honden* "five dogs," with fortis *h*. When these assimilations would give long consonants, they are simplified: *dat ding* "that thing," pronounced *dading; vijf vingers* "five fingers," pronounced *vijfingers; zes zakken* "six sacks," pronounced *zesakken*.

History.—Together with English, Frisian and German, Netherlandic belongs to the West Germanic group of languages. (*See* GERMANIC LANGUAGES.) It is descended primarily from the speech of the Franks who entered this area in the 4th and 5th centuries; in historical studies it is therefore often called Low Frankish. At the same time, it shows a few non-Frankish features ("Inguaeonisms"), which were probably borrowed from the former Germanic inhabitants of the coast. Documents written in Netherlandic do not begin to appear until the end of the 12th century. From the immediately preceding period there are only a few glosses, the names and occasional words that appear in Latin documents, and the single sentence *hebban olla uogala nestas bigunnan hinase hi[c] enda thu* "all birds have begun [their] nests save I and thou."

The development of Standard Netherlandic is closely tied to the political and economic history of the area. During the 13th and 14th centuries Flanders (in western Belgium) was culturally predominant, and Bruges the leading city. Toward the end of the 14th century the cultural centre began to shift eastward to Brabant, with Antwerp as the leading city. By the middle of the 16th century the speech of this region was well on its way to becoming standard for the whole area. Then came the revolt against Spain, in which the northern province of Holland played the leading role. Holland's cultural importance was greatly increased by the fact that many of the most influential southern families fled to the north, above all to Amsterdam, especially after the fall of Antwerp (1585).

The political split between the United Netherlands in the north and the Spanish Netherlands in the south had far-reaching linguistic effects. In the prosperous and vigorous north a standard language rapidly developed, based on the speech of the big cities of the province of Holland (especially Amsterdam) but also showing the influence of the culturally important refugees from Brabant. This has continued to develop as the standard language, down to the present. In the south, French came more and more to prevail among the upper classes. The less privileged classes continued to use dialectal Netherlandic, but no supradialectal standard was developed.

The cultural predominance of French increased during the period of French rule (1795–1814), abated somewhat during the years when Belgium and Holland were united independently (1815–30), but rose again after the founding of the kingdom of Belgium in 1830. At this time French was the only official language, used exclusively in government, courts and schools. Then there began a long struggle to give Netherlandic equal status with French, ending with the Language act of 1938, which made it the only official language of the northern part of Belgium. During these years of struggle there were attempts to set up a standard Flemish, different from that of the north; but in the end the standard Netherlandic that had become established in Holland was accepted for northern Belgium as well.

The close relationship of Netherlandic with English is most obvious in the consonants of the two languages: *plug* "plug," *tong* "tongue," *kan* "can," *bloed* "blood," *doen* "do," *gras* "grass," *hand* "hand," *man* "man," *naam* "name," *lip* "lip," *recht* "right," *winter* "winter," *jaar* "year." Former *f-* and *s-* are now *v-* and *z-*: *vinger* "finger," *zingen* "sing"; former *th* and *d* have coalesced as *d: dief* "thief," *diep* "deep"; former *al, ol* before *d, t* have changed to *ou*: *koud* "cold," *bout* "bolt"; former *ft* has changed to *cht: zacht* "soft." Former *sk* (English *sh*) gives *sch* initially: *schip* "ship," but *ss* or *s* elsewhere: *vis* "fish," plural *vissen;* former *hs* (English *x*) has also given *ss* or *s: vos* "fox," plural *vossen*.

Dialects.—At the border separating Holland or Belgium from Germany, the use of the standard language changes abruptly: Netherlandic is used to the west, German to the east. In the local speech, however, there is no such change: from the point of view of village dialects, the entire Netherlandic-German territory from the North sea to the Alps is a single dialect area with only gradual transitions from one village to the next.

In an area bounded roughly by Amsterdam, The Hague and Rotterdam, the local dialects are relatively uniform and do not differ greatly from the standard language. But north, east or south of this area, the local dialects diverge more and more from the standard language, until finally the two become mutually unintelligible. By tradition, dialects are named after the provinces in which they are spoken: Gronings in Groningen, Limburgs in Limburg, etc. In actual fact there are no sharp boundaries between dialects, but only more or less gradual transitions; and the relatively sharp transitions do not necessarily occur at provincial borders.

The use of dialect varies markedly. In the area Amsterdam-The Hague-Rotterdam, most rural inhabitants are puzzled at the suggestion that they speak a "dialect." Their speech is so similar to the standard language that they are not aware of any real differences. Even a few miles from this area, however, the differences become so great that everyone is fully aware of them. The result is that, throughout most of Holland, the vast majority of people in effect speak two closely related but distinct languages: Standard Netherlandic and local dialect, in varying degrees of proficiency.

In Netherlandic Belgium the use of Standard Netherlandic is much more limited, and that of local dialect is much more extensive. Some of the better educated speak the standard language fluently and use it regularly, while others prefer French. The less well educated use dialect almost exclusively, and are often able to handle the standard language only with difficulty.

NETHERLANDS, THE (NEDERLAND; officially KONINKRIJK DER NEDERLANDEN, popularly HOLLAND), a constitutional monarchy of northwestern Europe, bounded on the east by the Federal Republic of Germany, on the south by Belgium and on the west and north by the North sea. Its maximum length from north to south is 190 mi. and its greatest breadth is 160 mi. The coastline including estuaries is about 429 mi., which length is increased to 1,076 mi. if the coasts of close-lying islands are included. The Belgian municipality of Baarle-Hertog forms an enclave within the Dutch territory.

The area of the country has shown a continual variation. It has been decreased by coastal erosion and flooding by sea; on the other hand, these losses have been overcompensated by extensive silting and by artificial land reclamation, especially in the IJsselmeer area. The total land area of the Netherlands was estimated to be 13,96[illegible] sq.mi. by 1963. Approximately two-fifths of the country lies be-

I. PHYSICAL GEOGRAPHY

1. Geology and Structure.—The geology of the Netherlands is relatively simple, as most natural physical features date from the Quaternary stages (Pleistocene and Holocene periods), and their deposits cover most of the country in considerable depth. Tertiary sediments and earlier Mesozoic rocks are only met in borings on the east and south of the country or in rare outcrops in south Limburg and in the eastern part of the country. Carboniferous strata in which Coal Measures occur approach the surface in the northeastern part of south Limburg and, less closely, in De Peel region (between North Brabant and Limburg). In Limburg near Kerkrade these measures, lying close to the surface, have been worked since the middle of the 13th century. The Limburg mines work Coal Measures at a depth of 300 to more than 1,000 ft., while De Peel region coal lies at depths between 2,000 and 3,000 ft.

Permian and Triassic rocks underlie a great part of the country at considerable depths. They contain beds and domes of salt, which are exploited at Hengelo in Overijssel and near Winschoten in Groningen, and considerable quantities of oil and gas, chiefly at Schoonebeek (Drenthe) and near The Hague.

During the Pliocene period, the forerunners of the Rhine, Meuse (Maas) and Scheldt rivers deposited huge quantities of sediment, mostly sand, over the area. In the succeeding Pleistocene period ice spread over the northern part during the third (Riss) glaciation, depositing, in the provinces of Drenthe, Friesland and Groningen, large areas of boulder clay. Another legacy are the glacial ridges (*stuwwallen*) of Gelderland, Utrecht and Overijssel, which are the result of the folding up of the western slopes of the preglacial river valleys by the advancing ice sheet. Another element of the glaciated landscape is the broad depressions by which the melting water of the regressing ice sheet flowed off to the sea. Equally, the alluvial plain of the Rhine and Meuse rivers served this function. The glaciated regions, as well as the provinces of North Brabant and Limburg, that were not reached by the ice were later partly covered by aeolian deposits (*dekzanden*) during a dry part of the glacial period.

The postglacial period saw the return of sea level to approximately its present position. Then followed the initiation and subsequent development of an offshore bar, which was breached by the estuaries of the Scheldt, Meuse and Rhine but swept unbroken from the Hook of Holland to Den Helder and then continued in what are now the Frisian Islands. In time this bar was covered with sand dunes. The large lagoon behind the bar was partly filled up by a delta of river clay, built up by the Rhine and Meuse; partly, too, extensive peat areas developed in it, which were in some places covered by marine clay, where for a time the sea had breached the bar.

According to its geological history the Netherlands can be roughly divided into the following four areas:

The Southern Limburg Plateau.—This small plateau, thrusting for about 20 mi. between Belgium and Germany, and to the north reaching to about the town of Sittard, forms the oldest and most mountainous part of the country. Except for the valley of the Meuse, it consists of Cretaceous rocks, generally rising to more than 300 ft. and at some places in the south to more than 1,000 ft. The plateau is dissected by deep valleys with swift streams. Its surface is covered with a fine aeolian soil (loess) that is suited to wheat and sugar beet; the valleys are used for meadowland. Underlying Carboniferous deposits, a continuation of those in Belgium, have led to coal mining.

The Sand Areas of the South and East.—There at least three subareas may be distinguished: the most extensive of these is the nonglaciated region of North Brabant and northern Limburg, sloping gradually from southeast to northwest, with altitudes that rarely exceed 150 ft. The broad alluvial valleys of various streams and patches of peat bog, of which many are now reclaimed, form the most characteristic elements of this subarea. In the central part of the country there is a sandy region with alternating glacial ridges and broad valleys. The most westerly of these is the narrow belt of moraine hills of Gooiland and Utrecht, running from the Zuider Zee to the (Lower Rhine) Neder Rijn. The region is strongly wooded and the northern part is an extensive residential district. The ridge sinks to the east into the Geldersche valley, a region consisting mostly of sands. Between this plain and the broad valley of the IJssel lies the Veluwe plateau, consisting of a complex of glacial ridges that rise at some places to more than 300 ft. For its greater part it is still covered by heaths and woods and it serves to a high degree as a residential and recreational district. The valley of the IJssel consists of a rather narrow belt of river clay along the river, on both sides accompanied by a broader belt of low-lying sands. Across the valley of the IJssel the sandy regions of eastern Gelderland and Overijssel equally contain a number of glacial ridges, separated by broad alluvial plains. Formerly these plains were often marshy but, now drained, they are mostly used for meadows.

To the north of this latter region is the boulder clay plateau of Drenthe and the eastern half of Friesland. Formerly an area of extensive heaths, notably in Drenthe, it is now mostly reclaimed for agriculture. A series of depressions through which the melting water of the ice sheet was carried off border the plateau east and south. The sandy soil of these depressions was formerly covered by peat bogs as a result of insufficient natural drainage and the high level of the ground water. The peat has now been removed, giving rise to a special style of agriculture.

The Alluvial Plain of the Rhine and the Meuse.—The broad alluvial plain that stretches out through the central Netherlands is in fact a delta of the Rhine and its divergent distributaries. The Rhine itself divides soon after entering Dutch territory into the Waal and a more northerly stream, the Lower Rhine, later called Lek. At Arnhem the Rhine throws off an important distributary, the IJssel, which flows northward into the Zuider Zee. A third great river, the Meuse (Maas), flowing first north through Limburg, turns westward just below Nijmegen and winds several miles south of the Waal. The rivers are slow moving and meandering and deposit much silt. They are diked along considerable stretches, usually at some distance from their summer beds. The villages and their arable land are mostly situated on sandy levees along the river. The interior parts of this area lie at a lower

MODERN PROVINCES, MAJOR CITIES AND DRAINAGE OF THE NETHERLANDS

level and often show a marshy character (*komgronden*). The delta of the Rhine and the Meuse consists of fluvial clay that continues into the peat and marine clay of the coastal belt, with which it finally merges.

The Coastal Belt.—This can be divided into several zones. Stretching northeast from the Belgian frontier it is deeply indented by the wide estuaries of the West and East Schelde (Scheldt) and by those of the Rhine-Meuse, such as the Grevelingen and the Haringvliet. These estuaries themselves divide about the large islands of Walcheren, South and North Beveland, Schouwen-Duiveland, Tholen and Goeree-Overflakkee. Most of this area (including the islands), which is protected by dikes or sand dunes, is impoldered. Land reclamation has been in progress there for many centuries; the soil, a fertile marine clay, is suitable for arable farming. From the Hook of Holland a coast of sand dunes runs northward in a continuous sweep to Den Helder at the northern tip of the mainland. All its hinterland is below sea level; it is mostly protected by dikes and includes much polder land. Much of the surface area is peat or clay (on the bottom of the reclaimed lakes) and is suitable for various types of agriculture.

Stretching from the tip of North Holland in a northeasterly curve are the Frisian Islands (*q.v.*). They comprise, from southwest to northeast, Texel, Vlieland, Terschelling, Ameland, Schiermonikoog and Rottumeroog. The first three enclose a shallow stretch of tidal sea, the Wadden Zee, which led formerly into the Zuider Zee but was separated from it in 1932 by the Afsluitdijk (enclosing dike). The dam that connects North Holland with Friesland is 18½ mi. long and carries a motor road. The northeastern coastal belt of Friesland and Groningen to the German frontier is also extensively diked. Land reclamation is made in the more suitable places and the entire zone is poldered. The area consists largely of heavy clays and less extensive districts of peat.

2. Dikes and Polders.—To a great extent the physiogeographical structure of the country also decided the pattern of human occupation. The southern parts of Brabant and Limburg and the boulder clay plateau of Drenthe (with many megalithic monuments) form the oldest inhabited parts of the country. The lower and more marshy sand regions of the eastern sections of the country were occupied at a somewhat later stage, as was the inner side of the belt of the dunes. From these sandy areas settlement radiated first to the river clay delta and finally to the coastal belt of peat and marine clay. In the extreme north, in Friesland and Groningen, the earliest inhabitants settled on the unprotected marsh, but about the 1st century A.D. marine transgressions compelled them to build extensive mounds. Perhaps even as early as the 8th and 9th century attempts were made to secure greater protection by building dikes, and about the end of the 13th century different regions of the coastal belt were enclosed by dikes as protection against either the sea or the rivers. Later other dikes were built, sometimes as a consequence of flooding after the bursting of a dike, by which many villages often were devastated or even whole areas disappeared. In this manner the area southeast of Rotterdam was profoundly changed after floodings in the 14th and the first half of the 15th century. Most later dikes form part of successive reclamations, as for example the greater part of the isle of South Beveland, the whole isle of Overflakkee and extensive parts of Groningen and the southern part of South Holland. The most extensive undertaking by mid-20th century was the reclamation of a large part of the Zuider Zee (*q.v.*). Under a reclamation law (June 14, 1918) this was begun in the early 1920s with the creation of various polders; viz., the Wieringer meer, the Northeast Polder and East Flevoland. The reclamation of a fourth polder (South Flevoland) was begun in 1960. After the catastrophe of Feb. 1953, created by storm tides, in which 1,835 persons were drowned and 450,000 ac. of land flooded, a Delta commission was established to explore the possibilities of sealing off the Schelde and Rhine estuaries in South Holland and Zeeland. The Delta project, scheduled for completion in 1978, was accepted in 1957 and it was planned to dam

the estuaries and to shorten the southern coast line; dike building would eventually close the mouths of the Haringvliet, Grevelingen and East Schelde.

The problem that first arose from the embankment of the various parts of the coastal belt in the 12th and 13th centuries was the artificial removal of the superfluous precipitation. Since the beginning of the 13th century a complicated organization of the landholders has gradually developed to deal with this problem, by which the smallest units (polders) directly or indirectly (by the way of storage basins) have their superfluous water removed to the sea or the rivers. Formerly numerous windmills lifted the water from the land. Another form of reclamation consists of the breakup of the wasteland in the sand areas.

A most spectacular piece of reclamation in this field was that of the extensive peat bog in the northeastern part of the country, which was already started at the beginning of the 17th century. After the peat was dug off, the sterile sandy subsoil has been changed into arable land by means of manure and artificial fertilizers. In this way an extensive district of arable land was added to the Netherlands. (*See* LAND RECLAMATION.)

3. **Climate.**—The climate is rather uniform throughout the Netherlands, although in general the northern provinces are colder than the central and southern parts of the country. The prevailing winds are westerly and southwesterly, with a late spring period of cool northerly winds. High winds are fairly frequent in coastal areas. The mean winter temperature is around freezing and mean summer temperature about 21° C. (70° F.). Mean average rainfall varies between 22 and 32 in.; the wettest parts are the regions behind the dunes, the sandy areas in the middle of the country and southern Limburg. Marsh mists and sea fogs are common, particularly in winter. (H. J. KE.)

4. **Vegetation.**—Coniferous plantations cover 7% of the country and occupy 70% of the total woodland area. Deciduous woods are of three main kinds: oak-birch on poor sandy soils; oak-birch-beech on richer soils; mixed woods of oak, ash, hornbeam, cherry, etc., on the rich loam and chalk soils in the east and south. In the wetter places ash, alder, elm and willow trees are conspicuous. The extensive coastal dunes carry a varied flora: in the north, where the soil is poor in lime, their lichen carpet has been colonized by heaths, while the southern dunes, rich in lime, support scrub with common and sea buckthorn, privet, rose and spindle. Inland there are dry (*Calluna*) and wet (*Erica*) heaths, with crowberry in the north, and fens, swamps and sphagnum bogs. The salt marshes may be occupied mainly by *Salicornia*, salt-marsh grass, mud rush, or *Artemisia*, together with the cord-grass *Spartina townsendii*. Characteristic Atlantic species are bellflower, bell heather, myrtle and bog asphodel. (V. W.)

5. **Animal Life.**—The fauna of the Netherlands is characteristically western European. It shows a greater variety on the higher land than in the lower wetter areas. Fox, pine marten and tree frog are found only in the south and east. The southern part of Limburg, where there is limestone, has a fauna of its own with dormouse, midwife toad and wall lizard. In the national parks and nature reserves rare plants and animals are protected; *e.g.*, red deer in the forests and heathlands of the Hoge Veluwe National park (23 sq.mi.); bearded tit, purple heron, Savi's warbler and other marsh and water birds in the Naardermeer nature reserve (one of the most important bird sanctuaries in Europe); spoonbill on Texel Island (its most northerly breeding place); halophytes (salt-loving plants) and marsh and water birds on the Bosplaat sands of Terschelling Island. The change in the IJselmeer from salt to fresh water, following the closing of the Zuider Zee by a dike in 1932, has brought about interesting changes in the flora and fauna of that body of water. (X.)

II. THE PEOPLE

The modern Dutch people are descended from a few German tribes, chiefly the Frisians in the north of the Netherlands, the Saxons in the east and the Franks, who were of more southern origin, in the south. The Frisians arrived before the Christian era; the others came with the barbarian invasions in the 4th century A.D. In the course of many centuries these elements have become somewhat intermingled, especially in the western part of the country, which has been highly urbanized since the end of the middle ages. In the 17th century began a small and gradual influx into the towns of Jews (at first Portuguese, later German), of French Huguenots and of Malays and Eurasians from the (former) Netherlands East Indies.

Throughout history dwellers in the inland areas of the Netherlands have confined themselves largely to self-sufficient agriculture and to small industries; the spread of industry in the eastern and southern sandy regions is due to the availability of cheap labour.

In most aspects of their life the people are divided along confessional lines. According to 1959 estimates they were 44.5% Protestant, of whom about three-quarters (including the royal family) belonged to the Netherland Reformed Church (Nederlanse Hervormde Kerk) and the rest to a smaller Reformed body and such smaller groups as Mennonites and Lutherans. The Roman Catholic Church claimed 38% of adherents; and 17% of the population subscribed to no denomination. The proportion of Roman Catholics is slowly increasing because their higher birth rate coincides with the higher Protestant emigration rate. Political parties are divided along confessional and ideological lines. Religion and ideology exert influence also on schools, trade unions, occupational and recreational societies and even the national broadcasting and television systems, which are divided into several denominational branches in more or less sharp competition.

The Dutch people are also characterized by a strong family life and therefore greatly prefer one-family houses to flats, which have only begun to be built fairly extensively since World War II. The Dutch set much store by privacy and private initiative; they appreciate the moral value of autonomy and responsibility. Nevertheless, lack of space has obliged them to accept a high degree of material and social organization. Their rights are safeguarded by their strong democratic spirit, manifested in a long history of municipal government, water-defense corporations and, among the Protestants, by the Calvinistic church order which has penetrated all their denominations.

In general the Dutch are tolerant, sturdy and somewhat phlegmatic. Their artistic awareness is more visual than auditive—which, added to the fact that their language is not widely spoken, may account for the superiority of their painting and architecture over their literature. The average cultural standard is high; illiteracy is almost unknown and over 60% of young people receive secondary education.

There are many regional variations in Dutch life which play an important part in culture. These have, naturally, maintained themselves best in the rural areas and among the fishing population.

III. ARCHAEOLOGY

Paleolithic Remains.—The oldest remains of human industry in the Low Countries are Clactonian and Acheulean flints from gravels in the Mons (Hainaut) region of Belgium dating from the third (Riss) glaciation. Middle Paleolithic Mousterian industry is very well represented in Belgian alluvial and cave deposits (Hainaut, Liège and Brabant). Human (Neanderthal) fossils have also been found, especially in the cave at Spy. The Upper Paleolithic inhabitants (*homo sapiens*) of the northern provinces of the Netherlands were reindeer hunters, fishermen and food gatherers, who appeared in the final phase of the last glaciation (*c.* 10000 B.C.). They left flint implements closely related to the Hamburgian industry of northwest Germany. The Upper Paleolithic cultures in Belgium represent the northwesternmost limit of the classic Aurignacian, Perigordian and Magdalenian industries as known in France, Spain, Switzerland and southern Germany. The Low Countries have no Upper Paleolithic cave art; but some objects are decorated in typical French style.

During the final Paleolithic phase (Alleröd oscillation and younger Dryas, *c.* 9000–8000 B.C.) there were three cultures in the Low Countries, of which two appeared both in the Netherlands and

in Belgium, viz., the Tjonger group (so called from the Tjonger river in Frisia [Friesland]), related to the British Cheddar and Creswellian cultures; the Ahrensburgian, which derives from the Hamburgian; and, in southern Belgium only, the epi-Magdalenian.

Mesolithic Food Gatherers.—During Mesolithic times (8000–c. 4000 B.C.), which include the preboreal, the boreal and part of the Atlantic period, three groups of cultures are found. The first, the Maglemosian people, lived near lakes and rivers in the Netherlands, Flanders and most of the north European plain. Their remains consist largely of bone and antler points and harpoons. A fire-hollowed canoe of about 6000 B.C. discovered near Pesse, Drenthe, in 1955 probably belongs to this culture. The second group, the Tardenoisians, lived on high plateaus and in sandy regions throughout the Low Countries. They were hunters of small game and their remains consist of arrowheads and parts of composite implements made of geometrical microliths. Lastly there were the people who lived in the forests, whose characteristic remains are heavy tools suitable for woodworking, such as axes and adzes. These are found in Frisia (northern Netherlands) and around Liège (Belgium).

Danubian Farmers.—Farming people from central Europe settled in the Dutch province of Limburg and in the Hesbaye district (Belgium) at the end of the 5th millennium B.C. They brought the Neolithic way of life, based on agriculture and stockbreeding. Excavation has shown that their village consisted of large, wooden long houses, stables and barns. They cultivated cereals on loess soil cleared of forest by the slash-and-burn method and bred pigs, sheep and cattle. Among their most typical remains are shards of pottery decorated with wavy and angular incised lines and adzes made of polished hard or volcanic rock.

Spread of Neolithic Life.—After a few centuries the Danubians departed and were replaced by a second wave of Central European immigrants whose arrival originated two civilizations: the Funnel-Beaker culture in the Netherlands and the Michelsberg in Belgium. Both date from the third millennium B.C. The Belgian Michelsberg culture is much the same as the German, but it has also some affinities with the Windmill Hill culture of Great Britain. Among its most important remains are the flint mines of the Mons region (Spiennes), the products of which were used over a wide area. Its most characteristic feature is its pottery, with tulip beakers and flat baking disks. The remains of the Funnel-Beaker culture in the Netherlands are found mainly in the eastern provinces, especially Drenthe. There are numerous large megalithic passage graves, and pottery remains consist of funnel beakers, collared flasks, buckets and bowls decorated with deep horizontal and vertical grooves forming geometrical patterns. Excavations along the North sea coasts have revealed a series of farmers' and fishermen's settlements. These seem, however, to belong to an autochthonous Mesolithic population which had adopted the Neolithic way of life; their remains show strong Funnel-Beaker and western Neolithic influences.

Late Neolithic Migrations.—The end of the Neolithic period in the Netherlands is marked by a series of invasions and migrations. Warlike herdsmen arrived in the Netherlands from the east about 2200 B.C. Avoiding the Funnel-Beaker area, they settled in the Veluwe (Guelders) and at the western limit of the northern sandy areas. They buried their dead in single graves under barrows and left battle-axes of hard stone and cord-impressed beakers. About 2000 B.C. groups of prospectors of the Bell-Beaker civilization arrived, settling along the Belgian and Dutch coasts and in the provinces of Gelderland (Guelders) and Drenthe in the eastern Netherlands. They introduced the first metal objects. Some of them traveled on to the British Isles.

The Bronze Age (1600–600 B.C.) was a quiet period for the Low Countries as they lay outside the main trade routes. The period is chiefly memorable for its complicated timber-structured grave barrows. At the end of the Early Bronze age, people came from the British Isles to settle in the northern provinces of Belgium and the Netherlands. They cremated their dead and put the bones into urns which they placed under barrows. Typical of their rough funerary urns are those of Hilversum and Drakenstein.

Late Bronze Age: Urn Field Invasions.—During the Late Bronze Age, bronze weapons and implements began to be imported into the Low Countries from many parts of central and northern Europe, including the British Isles. Urn field people (probably Celtic), so called from their custom of putting the cremated bones of their dead into urns, came from Switzerland and the Rhineland to settle in northern Belgium and the southern Netherlands; *i.e.*, south of the Maas, Waal and Rijn rivers. Their equipment and grave goods were poor. In Flanders and central Belgium the genuine urn field tradition of flat graves was kept; while toward the north, barrows were adopted from the autochthonous population. North of the rivers came a large Germanic Urn field immigration originating from northwest Germany.

The Iron Age.—This period (600 B.C. to the Roman conquest, 12 B.C. onward) was very quiet north of the three rivers; the population of agriculturists and herdsmen continued the traditions of urn field times. About the beginning of the 3rd century B.C. the lower coastal stretch of Frisia was inhabited for the first time, by a population of cattle breeders. In order to protect themselves and their cattle from the high tidal floods, these new people built their villages on artificial mounds or *terpen*. The systematically excavated *terp* of Ezinge has yielded much information about their life. The area south of the rivers, however, presents a different picture. In the 7th century B.C. a group of Celtic (Hallstatt) warriors, probably from Bavaria, conquered central Belgium and established their rule over the autochthonous population. The Hallstatt influence was also felt in northern Belgium and the southern Netherlands; here there are a number of graves of chieftains, containing rich grave goods, including golden trinkets, mostly imported from the Mediterranean. During the La Tène period there were three cultural groups south of the great rivers. In the northernmost, the urn field traditions were still carried on, but the pottery was strongly influenced by the French Marne civilization. The strongest La Tène influence shows in the pottery, metal objects and gold ornaments of Hainaut. The Ardennes formed part of the Eifel-Hunsrück civilization. These last people built numerous hill forts (*oppida*) surrounded by stone and earthen walls.

The prehistoric period in the Low Countries ended with the conquest by Nero Claudius Drusus of the regions north of the Rhine (12 B.C. onward). (S. J. DE L.)

IV. HISTORY

For historical purposes, the name Netherlands, or Low Countries, is generally understood to include not only the territory of the Kingdom of the Netherlands, with which the nonhistorical sections of this article are concerned, but also what is now Belgium (*q.v.*) as well as parts of northeastern France and Luxembourg. Belgium, however, though it was not constituted as an independent kingdom till 1831, had a distinct history of its own from 1579, when the southern provinces of the Low Countries began to be separated from the northern. Here, therefore, the history of the Low Countries will be surveyed as a whole down to 1579; thenceforward the article will be concerned with the history of the northern area.

A. Early History, to 1384

Roman Occupation.—In 57 B.C. the Romans entered the northern borderlands of Gaul. There they found Celtic tribes: the Morini and the Menapii in the coastal belt west of the Scheldt, the Nervii in Hainaut and in Brabant east of the Scheldt and the Aduatuci in Namur. The Eburones, who were probably Germanic and who lived in the rest of Belgium and along the Rhine, were annihilated in war against the Romans. Their territory was then occupied, with the permission of the Romans, by other Germanic tribes, about the beginning of the Christian era: the Tungri in Limburg, the Toxandri in northern Brabant, the Cugerni and the Ubii in the Rhineland. In the region of the Rhine delta and to the north of that area the Romans encountered mainly the Batavi and the Frisians (*q.v.*), who were subjugated by Nero Claudius Drusus in A.D. 12. The Low Countries thus became part of the Roman empire for more than 400 years: revolts such as those of the Frisians (A.D. 28 and 47) and of the Batavi under

Gaius Julius Civilis (A.D. 69) did not permanently break Roman dominance.

Roman rule left clear and lasting traces and exercised a strong influence on the material civilization. The original centres of this Gallo-Roman civilization were the military camps, which in many cases were also centres of government. The network of roads and waterways connecting these camps remained important in later centuries. Such centres were founded along the Rhine border —at Trajectum ad Rhenum (Utrecht) and at Noviomagus (Nijmegen)—and also in the interior—at Aduatuca Tungrorum (Tongres), at Trajectum ad Mosam (Maastricht) and at Turnacum (Tournai). There were also numerous nonmilitary settlements and landed estates (*villae*), especially along the middle Meuse and in Limburg. Stimulated by commerce, industries developed; *e.g.*, iron mining, stone quarrying, pottery glazing and metalwork. One of the most important industrial regions was the Meuse valley.

The Franks.—In the first half of the 5th century A.D. the Romans evacuated the Low Countries. The Salian Franks (*q.v.*), who since the 4th century had been established as *dediticii*, or protected subjects of the Romans, in Toxandria (northern Brabant), used this opportunity to make themselves masters; they advanced in a southwesterly direction, settled in the area of Tournai and penetrated into Gaul. There, in the latter years of the 5th century, Clovis, at the head of the united Salian Franks, created the Frankish realm of the Merovingians, which thus had its centre outside the Low Countries. The Belgian territories, which in this way became borderlands of the Frankish dominion, stayed under Frankish rule, but they were very thinly populated. The Frisians meanwhile penetrated into the Rhine delta, and the coastal area was still very scantily peopled. This situation continued into the 7th century but was reversed toward the end of it: when Austrasia (*q.v.*) emerged as the most important part of the *regnum Francorum*, eastern Belgium (the middle Meuse area and the Ardennes) became one of its centres. Thereafter the Frisians were forced back behind the Rhine, and Utrecht was incorporated in the Frankish realm, at first provisionally but later definitely by Charles Martel, the mayor of the palace.

In the 8th century, when the Austrasian Carolingians came to power, Frankish rule was extended over the whole of Frisia. Thus the Low Countries—except for a Saxon area in the east—were absorbed into the Frankish empire. The form of government and administration which had been inaugurated under the Merovingians, and was continued under the Carolingians, provided the foundation for later institutions.

Subsistence was mainly from agriculture, though there were a few industries (metal on the middle Meuse and pottery in Hainaut and Namur) and some commerce (at Quentovic and at Dorestad), which was directed partly toward England, Scandinavia and northern France. Some municipal centres of Roman times continued to exist (Arras, Tournai, Maastricht, Utrecht).

Outside the centres of military and civil government there had been few traces of Christianity in Roman days. With the establishment of the Frankish realm and the conversion of Clovis, Christianity began to penetrate into the interior of the Low Countries, and a few dioceses (Thérouanne, Tournai, Tongres) were established in Belgium. The lasting Christianization of the southern Netherlands, however, was not achieved till the 7th century, largely thanks to missionaries belonging to the regular clergy (St. Amandus, St. Omer). In the river deltas and in Frisia, the Anglo-Saxon St. Willibrord (*q.v.*) began to preach the Gospel c. 690, choosing Utrecht and later also Echternach as his bases. In the north, evangelization was possible only with the support of the Frankish conquerors of Frisia. St. Willibrord's work was carried farther by St. Boniface (*q.v.*).

Christianization in the Low Countries was accompanied by monastic foundations, especially in the south (Elnone, Echternach, St. Vaast, St. Wandru, etc.); in the north, only the *monasterium* of Utrecht was of importance. A beginning was also made with the building of churches, mainly endowed by great landowners. While the south was evangelized by the Frankish mission and the north by the Anglo-Saxon, a third group of missionaries, the Irish-Scottish, was also of importance to the Low Countries in general because of its influence over Franks and Anglo-Saxons alike.

In the latter part of the 8th century, only the region east of the river IJssel (the modern province of Overijssel and the eastern part of Gelderland) remained outside the Frankish empire. St. Lebuinus tried in vain to propagate Christianity in this Saxon area, which was converted only after Charlemagne (*q.v.*) had finally subdued the Saxons at the end of the century. St. Liudger, of Frisian origin, then preached in the neighbouring Westphalia, where the diocese of Münster was established, and became its bishop. Pacification, Christianization and the development of the Frankish governmental and juridical institutions (feudalism, tribal laws, administrative organization) were, for the Low Countries, the most important results of Charlemagne's rule (768–814). When he was not at Aachen, Charlemagne resided frequently at Herstal on the Meuse north of Liège or at other places in the southern Netherlands, less often at Nijmegen.

The accession of the Austrasian Carolingians to power, the conquest of Frisia and the subjection of Saxony gave to the Low Countries south of the Rhine delta a central position in the Frankish empire, which they retained under the emperor Louis I the Pious. In his reign (814–840), however, peace was more and more disturbed by the devastating incursions of the Vikings, or Northmen; and toward the end of the 9th century these raids were penetrating ever deeper into the interior. Not until the beginning of the 10th century did peace return.

The disputes among the sons and successors of Louis the Pious and the resulting divisions of the Frankish realm likewise had a disturbing effect on the Low Countries. The treaty of Verdun (843), which assigned the West Frankish kingdom (Francia Occidentalis, or France) to Charles II the Bald and the East Frankish (Francia Orientalis, or Germany) to Louis the German, gave the so-called Middle kingdom (Francia Media) to the emperor Lothair I. This Middle kingdom included the Low Countries except the regions west of the Scheldt (the later counties of Artois and Flanders), which went to Charles the Bald; but after Lothair I's death (855) the Middle kingdom was once more divided. The northern part, which included the Low Countries, again with the exception of Artois and Flanders, went to the second Lothair (a younger son of Lothair I), after whom it came to be known as *Lotharii regnum*, or Lotharingia (*see* LORRAINE). Lotharingia was in turn partitioned between West and East Franks (870), attached in its entirety to the East Frankish kingdom (880), restored as an independent kingdom for the East Frankish king Arnulf's illegitimate son Zwentibold (895), attached again to the East Frankish kingdom (900) and even transferred by the local nobility to the West Frankish king Charles III the Simple (911). In 925, however, the Low Countries, once more with the exception of Artois and Flanders, were definitely attached to the East Frankish or German kingdom under the Saxon dynasty.

Territorial Independence and the Rise of the Towns.—In the course of the middle ages the Low Countries, linked as they were politically and ecclesiastically both with Germany and with France and economically and culturally with England, were able to exploit their position to make themselves gradually more independent. They also began to make an important contribution to the material and spiritual civilization of Europe.

In the movement toward greater independence the southern Netherlands took the lead. The merging of the numerous Carolingian administrative districts, or *pagi*, from the 10th century onward, brought larger political units into being. The feudal link between the kings and their greater vassals grew weaker (*see* FEUDALISM), and in the 12th and 13th centuries the counts, who had originally been officials of the kings, transformed their fiefs into practically independent lordships. The county of Flanders, the duchy of Brabant, the duchy of Limburg and the counties of Hainaut and of Namur (*qq.v.*) exemplified this in the south.

In the 11th and 12th centuries larger territorial units emerged likewise in the northern Netherlands, with the emergence of the county of Holland (*q.v.*) and the county of Gelder (*see* GELDERLAND), though Friesland remained in immediate dependence on the emperor.

Beside these secular territories two great episcopal territories had earlier come into being as a result of Otto I's ecclesiastical policy: Liège (*q.v.*) in the south and Utrecht (*q.v.*) in the north—the latter including also Drenthe and Overijssel. Until the concordat of Worms at the end of the Investiture controversy (1122; *see* GERMANY: *History*) the bishops strongly supported the authority of the empire and maintained close relations with the German kings. Of the northern territories, well into the 13th century, the principal centre was Utrecht, where the German kings frequently resided. Holland was next in importance, with its interests directed rather toward the south, while Gelder was more closely connected with the Rhineland and with Westphalia.

In the south, Flanders and Brabant, which both politically and economically developed earlier and more vigorously than any of the northern provinces, became pre-eminent. Their political institutions advanced under French influence, their towns grew up and their commerce and industry expanded. The towns of Bruges, Ghent, Ypres, Antwerp, Mechelen and Brussels owed their prosperity mainly to trade; and in the 14th century Flanders, with its cloth industry, became one of the commercial centres of Europe, while the count of Flanders was one of the most powerful rulers of the Low Countries. For the towns' emancipation from the control of the territorial lords *see* COMMUNE (MEDIEVAL).

In the north, towns and industries were of later origin: only in the 13th and 14th centuries did Middelburg, Dordrecht, Delft, Leiden, Haarlem, Arnhem, Nijmegen, Zutphen, Deventer and Kampen obtain municipal privileges, and in the 14th century they were still behind the towns of Flanders and Brabant.

The rise of the towns was accompanied by their struggle for political influence in their respective territories, in which they co-operated with the nobility and the clergy. This led to the growth of representative assemblies which were to become essential political institutions (*see* ESTATES-GENERAL).

In European affairs of the 13th–14th centuries, the Low Countries played a particularly notable role in the war between Otto IV of Brunswick and Frederick II for the German kingship, during which the Flemings, on Otto's side, took part in the campaign which ended in a victory for Frederick's ally, Philip II of France, at the battle of Bouvines (1214); in the troubles after the papal deposition of Frederick II, during which William, count of Holland, was proclaimed German king (1247); and at the outbreak of the Hundred Years' War, when both the English and the French sought allies in the Low Countries.

Meanwhile the principles of hereditary succession (through females in default of males), sometimes enforced by military action, had brought about dynastic unions between some of the great secular states of the Low Countries. Hainaut, after being temporarily linked with Flanders from 1067 to 1070 and from 1191 to 1280, was from 1299 linked with distant Holland, to which in turn Zeeland was attached from 1323. Brabant and Limburg were united under a single duke from 1288. The county of Artois, on the other hand, which had passed from Flanders to the royal house of France in 1191, was from 1329 linked dynastically with the county of Burgundy (*see* FRANCHE-COMTÉ). In 1382, however, Louis II de Male, the last count of Flanders of the house of Dammartin, inherited the counties of Burgundy and Artois from his mother, Margaret of France. Two years later Louis died, leaving his daughter Margaret as heiress, who in 1369 had been married to Philip the Bold, duke of Burgundy. (W. J. AL.)

B. BURGUNDIAN AND HABSBURG PERIODS, TO 1579

Burgundian Period.—The entry of Burgundian rule into the Low Countries proved decisive in their history. The Burgundian dukes of the house of Valois and the Habsburgs to whom their possessions in this area passed (*see* BURGUNDY) were bent on enlarging their patrimony and were successful, in the course of 160 years, in uniting the greater part of what came to be known as the Netherlands. The outcome was the birth of a Netherlands nation, but this was split into two parts before it could achieve maturity.

On Jan. 30, 1384, Philip the Bold (*q.v.*), duke of Burgundy, succeeded by right of his wife, Margaret de Male, to the counties of Flanders and Artois in the Low Countries, together with the county of Burgundy or Franche-Comté on the eastern frontier of his duchy, the county of Nevers on the western and the county of Rethel to the north of Champagne. Furthermore, Margaret's maternal aunt Joan, duchess of Brabant, in 1385 promised to leave Limburg and Brabant to the Burgundian couple and its descendants. She substantiated this promise in later transactions and as early as 1396 ceded Limburg (mortgaged to Philip from 1387). Philip meanwhile, to consolidate his position in the north, made full use of the opportunities offered by the virtual regency that he exercised in France during the minority and then during the madness of King Charles VI. After Philip's death (April 27, 1404), however, a partition of his dominions took place: the eldest son, John the Fearless (*q.v.*), received the duchy of Burgundy, to which Flanders, Artois and Franche-Comté were to be added on Margaret de Male's death (1405); the second son, Anthony (d. 1415), received Limburg and the administration of Brabant pending the duchess Joan's death, which took place in 1406; and a third son, Philip (also d. 1415), received Nevers and Rethel.

The energies of John the Fearless were chiefly absorbed in his struggle for supremacy in France till he was killed there (Sept. 10, 1419). His only legitimate son and successor, Philip the Good (*q.v.*), was able in a few years to triple his dominions in the Netherlands. Heir presumptive to his cousin Jacoba (*q.v.*), countess of Hainaut, Holland and Zeeland, Philip compelled her to surrender to him the government of her territories in 1428 and the titles also in 1433. With Holland went a claim to the Frisian lands, and so a perspective of expansion northeastward was opened. In 1429, moreover, the county of Namur came into Philip's possession in consequence of a purchase agreement of 1421. Then, in 1430, by the opportune death of his cousin Philip, Anthony's younger son, the collateral line ruling over Brabant and Limburg became extinct, so that these duchies also fell to Philip the Good. These important acquisitions made the house of Burgundy a power in its own right and loosened its bonds with France. By the peace of Arras (Sept. 21, 1435), Philip retired from the Hundred Years' War with substantial profits, including territorial gains in Picardy. His alliance with England had previously suffered from a clash of interests over Holland and Hainaut.

Nor was this all. From his uncle Anthony's widow, Elizabeth of Görlitz (d. 1451), Philip acquired the duchy of Luxembourg and county of Chiny (east of Sedan) through a series of transactions in the 1440s. By procuring the bishopric of Cambrai (Cambrésis) for his half-brother John (1439), that of Utrecht for his bastard son David (1456) and that of Liège for his nephew Louis of Bourbon (1456) he brought the territories of these sees under his protectorate. Other relatives ruled the duchies of Cleves and Gelder, and a number of petty dynasts in adjacent parts of Germany moved into the Burgundian orbit. Since, moreover, the German kings or Holy Roman emperors had by this time long ceased to exert any authority over Philip's new dominions, it was no mere flight of fancy when in 1447 it was proposed to raise them to the status of an independent kingdom, to which the suzerainty over a number of the peripheral principalities should be transferred.

Philip the Good never obtained a royal title, but he was in fact the equal of kings. He had united under his sway some of the richest and most populous regions of Europe, duchies and counties on both sides of the historical boundary between the kingdom of France and the empire—lands with different traditions, institutions and languages (though the linguistic and the political frontiers coincided hardly anywhere). A consequence of this personal union was the introduction of a certain uniformity into the administration of the various countries and the slow growth of a central government under the direction of the chancellor of Burgundy, from 1422 the able Nicolas Rolin (d. 1462). The unequaled splendour of the Burgundian court enhanced the prestige of the duke, who created a new vassalage by instituting (1430–32) the Order of the Golden Fleece, which strictly bound the most influential members of the nobility to their overlord. The foundation of a university at Louvain in 1425–32 introduced yet another unifying element. In Philip's last years deputies of the "estates" of all the Burgundian

dian Netherlands were called together for a common session—for the first time at Bruges, in Jan. 1464: thus emerged the estates-general, or states-general as they are generally called in connection with the Netherlands, later to become a factor of paramount importance.

The arrival of Burgundian rule encountered opposition in some territories, particularly in Holland and Zeeland; but everywhere the partisans of a strong government able to maintain law and order favoured the duke. In Holland these were to be found mainly among the burghers of the larger towns. In Flanders, however, the great cities, Ghent in the first place, strove to defend their position as virtually autonomous republics dominating the surrounding country. Their declining prosperity made them all the more intractable. The rebellions of Bruges (1437–38) and of Ghent (1451–53) were suppressed—that of Ghent only through a regular war culminating in the battle of Gavre (July 23, 1453)—and the more obnoxious of their privileges were revoked.

The decline of Flemish economy was caused partly by England's growing export of cloth, which had severe repercussions on the woolen industry of Ghent and Ypres; partly by the rising textile industries of Brabant and Holland; and partly by the gradual shifting of trade from Bruges to Antwerp. On the other hand, Brabant and, to a lesser degree, Holland profited from the relative tranquillity that prevailed under Philip's rule. Shipping from Holland and Zeeland expanded and penetrated into the preserve of the Hanseatic league, challenging its claim to a monopoly in the northern seas (naval war, 1438–41).

The vast complex of territories that Philip the Good had assembled passed undivided at his death (June 15, 1467) to his only surviving legitimate son, Charles the Bold (*q.v.*). Charles proceeded to augment and consolidate it. The gap between Brabant and Namur on the one side and Limburg and Luxembourg on the other was closed in 1468, when the episcopal principality of Liège was forcibly annexed, in all but name, to the duke's dominions; the duchy of Gelder was acquired in 1473; and for a short time a junction was achieved between the two Burgundies in the south and the Netherlands in the north by the overrunning of Lorraine in 1475. Other plans for territorial expansion—on the upper Rhine, on the lower Rhine, in Champagne and in Friesland—miscarried or failed to materialize. In the autumn of 1473, at a conference in Trier with the emperor Frederick III, Charles demanded to be elected king of the Romans or successor designate to the empire. Having been denied this, he seems to have fallen back on his father's project of 1447: a sovereign kingdom comprising his possessions within the empire, together with a number of dependencies, among them the duchies of Lorraine (as yet not conquered) and Savoy. Likewise, in this treaty of July 25, 1474, with his brother-in-law Edward IV of England against Louis XI of France, he stipulated for complete sovereign rights over his French fiefs.

Meanwhile, Charles reorganized the central government of the Burgundian Netherlands after the French example. Already, under Philip the Good, the specialized judicial and financial sections of the ducal or grand council had tended to become autonomous. A parliament was then created as a supreme court of justice, its seat being fixed at Mechelen. At the same time two boards of finance were set up, likewise at Mechelen, as was also a single chamber of accounts (ordinances of Thionville, Dec. 1473). These measures were partly due to the need for exploiting to the utmost the resources of the Burgundian "state" in view of Charles's incessant wars. Yet his harsh and exacting regime was far from popular and most of his reforms were swept away by the reaction that followed his death on the battlefield of Nancy (Jan. 5, 1477).

The catastrophe of Nancy put an end to the expansion of Burgundy. Lorraine was lost again. Louis XI of France claimed the reversion of the French fiefs, and his troops invaded Burgundy and Picardy. At the same time insurrection was rife in the Netherlands, where Charles's sole heiress, the duchess Mary (*q.v.*), had to face a strong particularistic, though not antidynastic, movement led by Ghent and encouraged by the French king. The states-general, which under Charles the Bold had been reduced to a machine for voting supplies of money, then came into their own. Meeting at Ghent, they forced the duchess to grant the "Great Privilege" (Feb. 11, 1477), which was supplemented by similar charters for the individual countries, strengthening local liberties and weakening central authority. The states-general moreover pressed at first for negotiations with France, but they gave Mary full support when they saw the true nature of French aims: particularism notwithstanding, a common loyalty prevailed. They also heartily approved her marriage, contracted by proxy in April and solemnized at Ghent in Aug. 1477, to the Austrian archduke Maximilian, son of the Holy Roman emperor Frederick III, of the Habsburg dynasty (*see* MAXIMILIAN I, Holy Roman emperor).

The First Habsburgs: Maximilian, Philip and Charles V.—When Mary of Burgundy died at the age of 25 (March 27, 1482), Maximilian became regent (1482–94) for their only son, the archduke Philip the Handsome, who was Mary's heir. Maximilian was compelled by the states-general (once again Ghent was the driving force) to conclude with France the second peace of Arras (Dec. 23, 1482). This confirmed the loss of the duchy of Burgundy and Picardy and also ceded Artois, Franche-Comté and other possessions in the south as the dowry of Philip's sister Margaret, who was promised in marriage to the dauphin, later Charles VIII of France. The states-general did not care much for these outlying districts, already occupied by the French king. After these amputations the Burgundian "state" could be identified with the Netherlands dominions, themselves then rather shrunken. Not only had Artois been lost, but Liège had regained its freedom, while Gelder and Utrecht had risen in rebellion. The peace, disastrous as it was for Burgundian dynastic interests, at least freed Maximilian to deal with the widespread insurrections and civil wars. It took him ten years to master them. A long conflict with Ghent after 1488 developed into something like national resistance when part of the higher nobility, led by Philip of Cleves-Ravenstein (a grandson of Philip the Good's sister Mary), joined the opposition against the unpopular foreign regent. But in 1492 internal peace was restored, though Gelder had to be given up. The war with France, which had been resumed in 1483, also came to an end. At the peace of Senlis (May 23, 1493), Franche-Comté and Artois returned into the Habsburg-Burgundian fold, as the proposed marriage of Margaret of Austria with Charles of France had fallen through. So Maximilian, then king of the Romans, could hand over to his son in 1494 a country that was reasonably tranquil and secure, and in which central government was functioning again.

More than any of his predecessors Philip the Handsome was a national ruler. He and his councilors kept up good relations not only with England (in Feb. 1496 a commercial treaty, the *Intercursus Magnus* or "Great Intercourse," was concluded with Henry VII) but also with France. Apart from a war, spasmodically waged, with Gelder, all was quiet, and the Netherlands began to recover from the years of turbulence. In 1504 the parliament of Charles the Bold was re-established under the name of grand council of Mechelen, while the former grand council continued to function through its more or less specialized departments. But not for long did Philip remain solely the ruler of the Netherlands. In 1496 he was married to Joan, daughter of Ferdinand II of Aragon and Isabella I of Castile; and a series of deaths in her family made him heir apparent to the Spanish kingdoms in 1500 and king of Castile in 1504. When he unexpectedly died at Burgos on Sept. 25, 1506, his Burgundian and Spanish lands passed to his eldest son Charles, born in Ghent in 1500 (*see* CHARLES V, Holy Roman emperor).

Maximilian, who became regent once more (1506–15), in 1507 appointed his daughter Margaret, then the widow of Philibert of Savoy, as governor general (*see* MARGARET of Austria). This office she held till 1515, when, at the instance of the states-general, the 15-year-old Charles was declared of age. Born and brought up in the Netherlands, he was popular there. These lands, however, had become connected with an empire with which they had few interests in common. At the age of 20 Charles was also king of Castile and Aragon (with their Italian and American possessions), head of the house of Austria and Holy Roman emperor as Charles V. So he had again to leave the Low Countries to the care of his aunt Margaret (from 1519 to 1530) and, after

her death, to his sister Mary, the widow of Louis II of Hungary (from 1531 to 1555). He had to make large financial demands on these rich provinces for purposes that did not concern them. Once more Ghent rebelled. The emperor dealt sternly with his native town: he revoked its privileges and gave it a new constitution (April 30, 1540). The rapid growth of Protestantism was another source of troubles for the government. Severe edicts against heresy were issued and enforced, and the papal Inquisition was introduced (1522) to supplement the activities of the bishops. On the whole, however, the rule of Charles and the "governesses" was moderate and successful. They extended the Burgundian dominions considerably in a northeasterly direction. The purchase and subjugation of Friesland (1515–24) was followed by the annexation of the bishop of Utrecht's lands (1528) and of Groningen and Drenthe (1536) and by the final recovery of Gelder (1543)—while control was also strengthened over smaller territories not formally incorporated (Cambrai and its environs; *i.e.*, Cambrésis) or only feudally annexed to one of the provinces (Tournai, *i.e.*, Tournésis). By 1543 Charles ruled over the so-called "17 Netherlands," a number perhaps not to be taken too literally, by which may have been meant Brabant, Limburg, Luxembourg, Gelder with Zutphen, Flanders proper, Artois, Hainaut, Holland, Zeeland, Namur, Walloon Flanders (Lille, Douai and Orchies), Tournai, Mechelen, Friesland, Utrecht, Overijssel with Drenthe, and Groningen—though sometimes Walloon Flanders and Tournai are not counted separately, while Zutphen and also Antwerp are.

By the middle of the 16th century the Burgundian Netherlands may have had a population of nearly 2,000,000, of which probably one-quarter was domiciled in Brabant, one-quarter in Flanders and one-sixth in Holland. This population was urbanized to an exceptional degree: more than one-third lived in Brabant, perhaps the same proportion in Flanders and more than half in Holland. Antwerp, the great commercial and financial metropolis, was by far the largest city: it had about 50,000 inhabitants in 1526 and more than 100,000 in 1566. The population of Ghent was steadily declining, from nearly 60,000 in the middle of the 14th century to 30,000 at the end of the 16th. Amsterdam was rapidly rising: it had perhaps 13,500 inhabitants in 1514, but already 30,000 by 1550; and it was to reach 100,000 early in the next century.

Charles V applied himself to welding these provinces together with constitutional links. He made the rules of hereditary succession the same for all of them, so that they should never be divided among different heirs (1549). He formalized the connection of his Burgundian lands with the Holy Roman empire by re-creating the "Burgundian circle" (nominally existing from 1512) in 1548 as one of the "imperial circles" or *Reichskreise*. In this circle, moreover, Flanders and Artois, previously fiefs of the French crown, were included, since Francis I of France had renounced French suzerainty over them in the treaty of Madrid, signed during his captivity in Spain (Jan. 13, 1526). Charles also developed the governmental machinery taken over from his predecessors. On Oct. 1, 1531, the chancellorship was abolished, and the grand council (*i.e.*, the nonjudicial sections) was divided along departmental lines into three councils collateral to the governor general: the executive privy council, the council of state and the council of finance. At the same time the seat of government was transferred from Mechelen to Brussels. The different principalities, which had gradually become provinces, retained their own particular councils with administrative and judicial competencies, under their stadholders (governors), who were high noblemen appointed as representatives of the sovereign.

THE NETHERLANDS AFTER THEIR CONSOLIDATION UNDER CHARLES V IN 1543

Philip II of Spain and the Revolt.—On Oct. 25, 1555, at a meeting of the states-general in Brussels, Charles V abdicated the sovereignty of the Netherlands in favour of his son, who next year likewise became king of Spain as Philip II (*q.v.*). The new ruler aimed at the further unification of the Netherlands under a strong monarchy—a policy less acceptable to his northern subjects because he was a Spaniard in his sympathies and views. In 1559 the peace of Câteau-Cambrésis, which terminated the French-Spanish war, opened the gate for Calvinist preachers from France who soon made many converts in

the Netherlands. Philip was determined to crush heresy, now growing into a formidable force. Therefore, but chiefly in order to adapt the ecclesiastical organization of the Netherlands (Luxembourg excepted) to the political structure, he began in 1559, with papal approbation, to divide the Low Countries into smaller dioceses with a more efficient and subservient episcopate: 18 in all were set up (including 3 archiepiscopal sees), 14 of which were entirely new. This measure was resented in many quarters, especially in Brabant and in the northeastern provinces, not only by the Protestants but also by the higher nobility and clergy and by all who opposed monarchical absolutism and ecclesiastical rigorism.

At first, religious questions were not foremost among the causes of discontent, but gradually they became of increasing significance. The encroachments on cherished liberties and traditional rights and the subordination of the Burgundian lands to Spain were the primary, and remained the most general, grievances. In the face of the hesitation of the authorities, however, during the governorship of Philip's half sister Margaret of Austria, duchess of Parma, whom he appointed on his departure to Spain in 1559, the opposition grew more radical in successive stages as the leadership of it passed from the great nobles to the gentry and then from the gentry to the Calvinist ministers and burghers. The league of the magnates, headed by William I the Silent (*q.v.*), prince of Orange, by Lamoral, count of Egmond (*q.v.*), and by Phillip de Montmorency, count of Horn, obtained in 1564 the retirement from the Netherlands of the cardinal archbishop of Mechelen, Antoine Perrenot de Granvelle (*q.v.*), who had been made to bear most of the blame for the grievances; but soon there emerged a league of the lesser nobility, at the head of which were William's brother Louis of Nassau and Hendrik, lord of Brederode (*q.v.*). This league on April 5, 1566, forcefully presented to the government a "request" for the withdrawal of the Inquisition and of the most rigorous edicts against heresy; and at a subsequent banquet Brederode's friends bound themselves together in the confederacy of the Gueux (*q.v.*). Thereafter extreme Calvinists and fanatics of all sects redoubled their activity. Field preaching spread like wildfire; social discontent, caused by inflation and by the slump in the textile trade, was rife. In Aug. 1566 many places, especially Antwerp, were alarmed by iconoclastic riots. The Calvinist burghers and gentry (as yet a small minority) were forming armies. The general confusion, however, caused most of the great nobles, many of the gentry and orderly people in general to rally to the government. William, by attempting to mediate, lost the confidence of both sides. Margaret raised a considerable force of German mercenaries, which destroyed the ill-organized Calvinists in West Flanders and before Antwerp. She now had the situation well in hand, but in Aug. 1567 a veteran Spanish general, the duque de Alba (Fernando Alvarez de Toledo) arrived from Italy at the head of an army.

Alba, whom King Philip soon appointed to Margaret's place as governor (1567–73), at once inaugurated a reign of terror. A special tribunal, the Council of Troubles, nicknamed the Council of Blood, was set up; there were wholesale executions, the most famous victims being Egmond and Horn (June 5, 1568). William was outlawed (Jan. 1568) and his attempts to invade the Netherlands from Germany were defeated. By the end of 1568 Alba was the undisputed master of the country.

In 1572 events took a new turn. The Gueux captured the port of Brielle (Brill) on April 1 and Flushing a week later. Henceforth the rebels, who recognized William as their chief, had a foothold of their own in the Netherlands. Thanks to their naval superiority they could maintain themselves in the "sea provinces" (Holland and Zeeland), which became a refuge for Protestants from the south. In the south, however, as also in the eastern provinces, almost simultaneous movements of rebellion were overpowered: Louis of Nassau took Mons in May, but had to surrender it in September when William's army from Germany failed to relieve him. Even so, by pinning the Spanish field force down in the south, Louis and William had given the insurgents in Holland their chance: three months after the capture of Brielle, Amsterdam was the only town in Holland in the hands of the government. In July the estates of Holland re-appointed William as their stadholder and on Oct. 21 he himself arrived to take command. Meanwhile Alba's son, Don Fadrique de Toledo, and his army moved northward, committing abominable atrocities at Mechelen, Zutphen and Naarden. Yet Haarlem heroically held out from Dec. 11, 1572, till July 13, 1573, and the eventual slaughter of its garrison did not paralyze further resistance. Finally, at Alkmaar, victory passed to the side of the rebels: the dikes were cut and Don Fadrique withdrew his troops before the advancing floods (Oct. 8, 1573). Three days later Alba's fleet was defeated on the Zuider Zee. His soldiery was unpaid and mutinous. He had lost the confidence of the king, and in Dec. 1573 he left Brussels forever.

By the time of Alba's departure his successor, the more conciliatory Luís de Zúñiga y Requesens, had already arrived. Hampered by lack of money and by the stiffening resistance of the provinces still under Spanish rule, he sought for a compromise. On the religious issue, however, the views of the king and those of the rebels were irreconcilable; so fighting went on. In 1574 the defeat of a Spanish fleet on the Scheldt (Jan. 29) led to the surrender of Middelburg to the Gueux (Feb. 18); then a great victory over the Orangists on the Mookerheide or Mook heath near Nijmegen, where William's brothers Louis and Henry were both killed (April 14), enabled the Spaniards to resume their siege of Leiden; but the final relief of Leiden by the Gueux (Oct. 3) was a triumph which the estates of Holland and Zeeland commemorated by the foundation of a university there. A new Spanish offensive against Holland met with some success in 1575, and another offensive against northern Zeeland culminated in the capture of Zieriksee on June 30, 1576. By then, however, Requesens had died (March 5, 1576) and the council of state had taken over the government. All the money had run out, and in July the unpaid troops in Zeeland mutinied (as other Spanish forces did elsewhere) and marched off to Brabant and Flanders.

The Pacification and the Unions.—At the sudden collapse of Spanish power the smouldering discontent in the south burst into flame. The estates of Brabant, Flanders and Hainaut clamoured for peace and pressed the council of state to convene the states-general, which then entered into negotiations with William. A peace conference was opened at Ghent on Oct. 19, 1576, between representatives of William, Holland, and Zeeland on the one hand and of the states-general in Brussels on the other. The Pacification of Ghent was signed on Nov. 8. Meanwhile, on Nov. 4, the mutineers had fallen upon Antwerp and sacked the city with a barbarous ferocity long remembered as "the Spanish fury."

By the Pacification of Ghent the unity of the "common fatherland" was restored, and it was agreed that Spanish troops should be expelled from the Netherlands. The religious question, however, was left undecided. On Jan. 9, 1577, a formal union, concluded at Brussels, strengthened the bond between the provinces, though its religious provisions did not satisfy the Protestants. William then prevailed on the states-general to make its recognition of the new regent, Philip II's half brother Don John of Austria, conditional on his acceptance of the Pacification. Don John accepted it unwillingly, by the "Perpetual edict" (Feb. 12), on the understanding that Catholicism was to be maintained everywhere. The Spanish troops were paid and they left the country.

Hitherto the great majority of the population had been neither adherents of the Counter-Reformation nor downright Calvinists, but gradually the religious issue became more clearly defined, with the beginning of a rift between Catholic and Protestant provinces. As the Union of Brussels and the Perpetual edict gave them insufficient guarantees, the estates of Holland and Zeeland withdrew their deputies from the states-general. The difference was temporarily overcome by the action of Don John, who suddenly took the citadel of Namur (July 1577) and defied the states-general. William then became the leader of the Union, though his position was not undisputed. To counter his ascendancy, some southern nobles invited the archduke Matthias (later Holy Roman emperor), a nephew of Philip II, to come to Brussels; and the states-general in Jan. 1578 put Matthias at the head of a national government, but with William as his lieutenant general. Shortly

before (Dec. 10, 1577), a new Union of Brussels had insisted on the duty of mutual assistance by adherents of both religions.

Unity and union were short-lived. Once again the revolution slid toward religious and political extremism. William was compromised by his alliance with the turbulent democrats and Calvinists in Brabant and in Flanders, such as Jan van Hembyze; and the violent introduction of Calvinism in a number of towns, together with the excesses of the Reformed and radical factions, were strongly resented by the Catholics. A religious peace, proclaimed at William's instigation by the states-general on July 12, 1578, availed little.

In the meantime Philip II had sent a new Spanish army under Alessandro Farnese (*q.v.*), Margaret's son and the heir to the duchy of Parma, to help Don John. After defeating the national troops at Gembloux (Jan. 31, 1578), Don John had then conquered a number of towns. He also won some adherents in the Walloon, or French-speaking, provinces and among the nobility; and this gravitating of alarmed traditionalists toward the king's legal representative continued when the duc d'Anjou (François Hercule; *see* ALENÇON, DUCS D'), chosen regardless of Matthias by the states-general as "defender of the liberties of the Netherlands" in Aug. 1578, failed to establish himself promptly. When Don John died (Oct. 1) and was succeeded by the able Farnese, the general union of the Netherlands provinces was already breaking up.

On Jan. 7, 1579, Hainaut, Artois and Douai inaugurated a league of their own, the Union of Arras for the defense of the Pacification and of the Catholic religion. Thereupon another league, the Union of Utrecht, based on the Pacification and the religious peace, was concluded on Jan. 23 between Holland, Zeeland, Utrecht, the nobility of Gelderland and rural Groningen (the Ommelanden), soon to be joined by Ghent, Bruges, Ypres, West Flanders, Antwerp and other towns of Brabant, the towns of Gelderland, Drenthe and parts of Friesland and also by William. This Union of Utrecht did not yet create a separate republic of the northern Netherlands: the general union was broken only when the Union of Arras withdrew from the Union of Brussels and submitted to the king (May–June 1579). It was left to the fortunes of war to decide the future dividing line between the two Netherlands. (A. G. J.)

C. THE UNITED PROVINCES

Spanish Reconquest of the South.—Under Alessandro Farnese the Spaniards and their adherents in the Netherlands made such progress against the forces of the Union of Utrecht that in less than seven years from 1579 the whole of the south was reconquered from it. Already in 1579 Maastricht fell to Farnese and 's Hertogenbosch opened its gates to the Spaniards; and in 1580 the stadholder of Groningen went over to the Spanish side. Philip II then felt strong enough to outlaw William I the Silent, leader of the Orangists, again, but William continued to seek foreign help and finally succeeded in persuading the duc d'Anjou to accept the sovereignty of the Netherlands. Anjou's expected arrival forced the states-general, meeting at The Hague, at last to repudiate the sovereignty of Philip II. The document (the so-called *Verlatinge*) to which they assented on July 26, 1581, enumerated all the tyrannical acts whereby Philip was held to have forfeited his right to rule the Netherlands. Yet though Anjou was subsequently installed as sovereign in some provinces, these provinces made conditions severely restricting his powers, while Holland and Zeeland refused to receive him at all. In any case, Anjou proved not only useless as a general against Farnese but also inept as a statesman. Irritated by the restraints on his power, he tried to subjugate Antwerp by a *coup d'état*, the so-called "French fury," in Jan. 1583. When this failed, he retired, completely discredited, to France, where he died on June 10, 1584. William, who remained organizing resistance from his refuge in Delft, was about to accept the offer of Holland and Zeeland to appoint him as their count when he was assassinated on July 10, 1584, by a fanatical young Catholic, Balthazar Gerard.

With the Spaniards steadily overrunning Flanders and Brabant, the Dutch in their desperate plight offered the sovereignty of the Netherlands to Anjou's surviving elder brother, Henry III of France, but in March 1585 Henry declined the offer. The states-general then addressed themselves to Elizabeth I of England. These negotiations were still proceeding when Farnese, after a long siege, took Antwerp (Aug. 1585), thus completing his reconquest of the southern Netherlands. The representatives of the southern provinces then withdrew from the states-general.

English Intervention.—Elizabeth of England declined the sovereignty of the Netherlands, but the news of the fall of Antwerp made her decide to come to the rescue of the Dutch. By a treaty of Aug. 20 (new style; 10, old style), 1585, she agreed to send 6,000 men under her favourite, Robert Dudley, earl of Leicester, while the Dutch were to guarantee payment of the English expenses and to surrender the towns of Flushing and Brielle and the fort of Rammekens as security (only in 1616, when the Dutch debt was settled, did the English leave these places). In Dec. 1585 Leicester arrived in Holland. Meanwhile Holland and Zeeland had in Nov. 1585 appointed as stadholder the 17-year-old Maurice (*q.v.*), William the Silent's second son (his elder half brother Philip William was in the hands of the Spaniards). A new council of state was established in order to improve the working of the government of the union; but meanwhile Johan van Oldenbarnevelt (*q.v.*), advocate of Holland from March 1586, acquired great influence. There was at first great willingness among all the Dutch statesmen to co-operate closely with Leicester, and the states-general appointed him governor general—an office which, against his queen's orders, he accepted. After the first few months, however, deep misunderstandings between Leicester and the Dutch ruling classes became apparent. He tried to transform the loose federation of provinces into a more united state, but lost Holland's support by disregarding the fact that Holland was by far the strongest of the provinces and the real centre of the union (he himself resided at Utrecht). He wanted moreover, to accentuate the strictly Calvinistic character of the state and thereby alienated the most influential latitudinarian groups in the various towns and estates. His attempt, finally to forbid trade with Spain was disastrous, as this trade provided the Dutch with the means to carry on the war against the Spaniards. Leicester was also incompetent as a general. Farnese, then duke of Parma, proved his superiority by taking Grave and Venlo in 1586 and Sluis in Aug. 1587 (after Deventer and the siegeworks before Zutphen had both been betrayed to the Spaniards by the English Catholic commanders appointed by Leicester). Made still more unpopular by a peace move which Elizabeth compelled him to undertake, Leicester attempted a *coup d'état* but failed. In Dec. 1587 he left Holland; and in April 1588 the states-general accepted his resignation.

Emergence of the Republic.—After Leicester's departure it became clear that the state for which the United Provinces were fighting would probably not be a monarchy, and no more approaches to foreign princes were made. The government of the union, however, which was kept as Leicester had left it, without fundamental alterations, was essentially that of a truncated monarchy. Because the seven provinces which eventually came to form the Dutch republic—namely, Gelderland, Holland, Zeeland, Utrecht, Friesland, Overijssel and Groningen (Drenthe was only a "territory" and sent no delegation to the states-general)—never concluded a new treaty among themselves, the Union of Utrecht of 1579, to which in fact not all of them had subscribed, remained the only formal link which could be regarded as a constitution for the United Provinces as a whole. Yet its only purpose had been to make possible some measure of collaboration between the provinces after the collapse of the Habsburg central authority and it had done nothing to determine the form of government for the union. Thus the Dutch republic emerged as a loose federation in which sovereignty resided not with the states-general but with the estates of the seven provinces. Each of these had one vote in the states-general, whose decisions were, in principle, taken unanimously. The various estates also acquired the right to appoint the stadholders of the provinces, but in practice Holland and Zeeland never appointed anyone other than the prince of Orange and Friesland and Groningen usually appointed the count of Nassau, while most of the other provinces generally followed the ex-

ample of Holland and Zeeland. From 1625, moreover, the stadholder of Holland and Zeeland was nominated as captain- and admiral-general of the union by the states-general; and though the states-general acted as the official representative of the union it was generally the prince of Orange or the pensionary (*q.v.*) of Holland who determined foreign policy. In the years following 1588 the European powers gradually recognized the existence of the new republic of the United Provinces.

"The Ten Years" (1588–98) and the Truce of 1609.—The old Burgundian territories north of the Rhine and Meuse rivers which the Union of Utrecht had lost between 1579 and 1588 were recovered by the Dutch in the following decade, thanks chiefly to the diversion of the Spanish military effort to other fields. First Parma's strength suffered from the defeat of the Armada (1588) and then he was ordered by Philip II to intervene in the French civil wars. Also, his immediate successors, after his death in 1592, were less able soldiers and statesmen. Meanwhile Maurice, stadholder and also captain general of Holland and Zeeland from 1585, of Utrecht and Overijssel from 1590 and of Gelderland from 1591, reorganized the army in close collaboration with his cousin William Louis, stadholder and captain general of Friesland from 1584. Inspired by Roman military science and mathematical studies, Maurice and William Louis designed a new strategy and created a small but efficient fighting force, strictly disciplined and well-equipped: it soon became a model and a training school for Europe. Maurice captured Breda, Crèvecoeur and Steenbergen in 1590, Zutphen, Deventer, Delfzijl, Hulst and Nijmegen in 1591, Steenwijk and Coevorden in 1592, Geertruidenberg in 1593 and Groningen in 1594. Thus most of the territory north of the Rhine and the Meuse was firmly in Dutch hands; and in 1595 the states-general laid garrisons in the German towns of Emden and Leerort. The year 1596 brought the *de facto* recognition of Dutch independence by France and England, which concluded a triple alliance with the new republic. In Jan. 1597 Maurice's cavalry defeated a superior Spanish force at Turnhout; and later in the year he drove the remaining Spanish troops out of the eastern parts of Gelderland and Overijssel. Thereafter Maurice was unable to make further conquests, except Sluis in 1604. The great consolidating period called "the Ten Years" (1588–98) was terminated.

In 1598 Henry IV of France, considering the support that England was providing to be insufficient, made the peace of Vervins with Spain, promising however to continue to help the Dutch with money. But Spain, weakened by unsuccessful maritime expeditions and financially exhausted, did not profit by this peace. Philip II tried to bring about a reconciliation between the northern and the southern Netherlands: just before his death he arranged the marriage of his daughter Isabella to the cardinal archduke Albert of Austria, granting them as dowry the sovereignty of the Netherlands—in theory of the whole country, in practice of course only of the southern provinces (1598). The Dutch, however, declined Albert's offers of reconciliation, as neither party could make concessions in the religious sphere. Yet the Dutch resigned themselves to the south remaining Catholic and gave up their hope of winning it. This attitude was to some extent determined by economic reasons. The closing of the estuary of the Scheldt, by which the states-general had reacted to the Spanish occupation of Antwerp, proved a boon to the commerce of Amsterdam; and it was clear that the unparalleled economic development of the republic, which began in this period and was demonstrated by Dutch ventures in the East Indies (*see* DUTCH EAST INDIA COMPANY), would be hampered if the southern Netherlands were to acquire free access to the sea. The war on land became subordinate to the maritime conflict.

Maurice's famous march through Flanders, ending with his fruitless victory at Nieuwpoort (1600), was aimed at the Dunkerque privateers. The Spaniards succeeded in taking Ostend from the Dutch after a three-year siege (1604). The formidable general and statesman Ambrogio di Spinola, who was the leading personality in the government of the southern Netherlands, then started attacking the eastern frontiers of the republic and took Oldenzaal and Lingen in 1605 and Grol and Reinberg in 1606. Since James I of England had made peace with Spain in 1604, Oldenbarnevelt, the political leader of the republic, then became convinced of the necessity to end the war and accepted the archduke Albert's long-standing offer to start negotiations. Partly thanks to French mediation, a 12 years' truce was at last concluded on April 9, 1609; for the duration of the truce, the *status quo* was to be preserved in Europe as well as in the East and West Indies. This great success of Oldenbarnevelt's diplomacy was, however, contrary both to the mercantile interests of Amsterdam, which wished to carry on the war against Spain in the West Indies, and to the political aims of Maurice; it was therefore one of the causes of the domestic conflicts which filled the period of the truce.

Arminians and Gomarists.—A conflict within the Reformed or Calvinist Church (which represented as yet only a minority of the Dutch population) led to a political conflict of long-lasting effect. In an effort to define the Calvinistic dogma of predestination the Leiden professor Franciscus Gomarus (*q.v.*) challenged the views of his older colleague Jacobus Arminius (*q.v.*). Gradually the whole church was compelled to take sides. The estates of Holland, many of whose members did not belong to the Reformed Church at all, tried at first to mediate; then, when mediation failed, most of them—with the notable exception of Amsterdam—supported the Arminians because they were a minority in danger of being driven out of the church by their opponents and because their views, being less strict and exclusive, were less likely to estrange outsiders. In 1610 the Arminians addressed a "remonstrance" to the estates of Holland, asking for help, after which they were called Remonstrants; it was answered by a counter-remonstrance of the Gomarists, then called Counter-Remonstrants. In 1614 the majority of the estates of Holland forbade the ministers of the church to meddle in the dispute; the Gomarists who refused to submit to this order were driven out of those towns where the municipal administrations were in favour of the Arminians. In July 1617 Maurice, although not interested in the doctrinal problem, openly declared his support for the Gomarists, and the majority of the states-general followed him. The conflict became one between Maurice, the majority of the states-general, Amsterdam and the Gomarists on the one hand and Oldenbarnevelt, the majority of the estates of Holland and the Arminians on the other. In Aug. 1617 Oldenbarnevelt attempted to strengthen the municipalities of Holland by means of the so-called "Sharp Resolution," whereby the estates authorized them to engage troops of their own for the preservation of order, thus undermining the authority of the captain-general. After a year of tension, Maurice, backed by the majority of the states-general, had the leaders of the opposition, including Oldenbarnevelt himself and the great jurist Hugo Grotius, arrested (Aug. 1618). A special tribunal sentenced Oldenbarnevelt to death (he was executed on May 13, 1619) and some of his followers, among them Grotius, to life imprisonment. A national synod was convened at Dordrecht (Dort) and, as expected, condemned Arminian doctrine (Nov. 13, 1618–May 9, 1619). The leading Remonstrants left the country and found refuge in Antwerp.

Maurice then wielded nearly unlimited power. But he failed to use it for improving the constitution or for breaking the power of the urban oligarchies in Holland. The only important political decision taken by him after 1619 was his refusal to allow an extension of the 12 years' truce of 1609 in 1621—when, moreover, the archduke Albert's death without issue had brought the southern Netherlands back under Spanish rule. Thus war was resumed and public attention was once more diverted from internal strife to the struggle with Spain. The international situation, however, became complicated by the course of the Thirty Years' War (*q.v.*), which had begun with Bohemia's revolt against the Austrian Habsburgs in 1618. Maurice was not equal to the new circumstances, and the few years left to him were years of frustration. He died on April 23, 1625.

Frederick Henry and the Thirty Years' War.—Maurice was succeeded by his younger half brother Frederick Henry (*q.v.*) as stadholder of five provinces and as captain- and admiral-general of the union. An abler politician than Maurice and a competent soldier, he resumed in many respects the ideals of his father, Wil-

liam I the Silent. He was religiously tolerant and allowed the Remonstrants to return and to preach their doctrine openly: they acquired much influence among the patricians of the municipalities and the intellectuals. Also, the political power that Maurice had won for the stadholdership but had left unused then became effective. Frederick Henry could assume a semimonarchical status which enabled him to determine foreign as well as domestic policies. No longer did the advocate of Holland—called the grand pensionary (*raadpensionaris*, or salaried councilor)—dominate the republic as in Oldenbarnevelt's days. Only men prepared to follow the prince's directives were appointed to the standing committee of the states-general, which from 1630 onward administered foreign affairs. Frederick Henry moreover maintained a fashionable court at The Hague and was interested in painting and architecture. His court however did not become the centre of that Dutch civilization which, retaining its essentially bourgeois character, in this period reached its greatest achievements in all fields. At the same time Dutch economy developed at an astonishing pace into unchallenged European supremacy. Dutch settlements were established in the East and West Indies and in South and North America, including New Amsterdam, which later became New York city (*see* DUTCH EAST INDIA COMPANY; DUTCH WEST INDIA COMPANY). All this makes Frederick Henry's time of office one of the most brilliant periods in the history of the republic.

When the war with Spain had been resumed in 1621, the Dutch had at first been unable to halt Spanish raids in the eastern and northern provinces; and in June 1625 they had lost the important town of Breda. After 1625, however, they were fairly successful in defending their small territory. The stadholder of Friesland, Ernest Casimir of Nassau-Dietz, took Oldenzaal in 1626, and Frederick Henry captured Grol in 1627. Then the capture of the Mexican silver fleet from the Spaniards by Piet Hein in 1628 provided the Dutch with the money that they so badly needed; and in 1629 Frederick Henry was able to besiege and take 's Hertogenbosch, thus carrying the war south of the big rivers and opening the possibility of reconquering the southern Netherlands. This prospect met with some encouragement in the southern Netherlands themselves, but the Dutch campaign of 1632, which was intended to strengthen the southerners' opposition to Spain, petered out after some initial successes, the most notable of which was the capture of Maastricht in August. Peace negotiations between the southern and the northern Netherlands failed in 1633.

When France, under the ministry of the cardinal de Richelieu, was about to enter the war openly against Spain, the states-general and the French agreed to divide the southern Netherlands between them and promised to make peace only "jointly and by common consent" (treaty of Paris, Feb. 1635). It proved impossible, however, to conquer the southern Netherlands. Frederick Henry took Breda in 1637 but failed in his attack on Antwerp in 1638 and achieved only two more successes in the remaining ten years of the war: the capture of Sas van Ghent in 1644 and of Hulst in 1645. At sea, on the other hand, Spanish power received a smashing blow when on Oct. 21, 1639, a great fleet of warships and transports was destroyed in the Downs by Maarten Tromp.

During the 1640s Frederick Henry's position grew gradually weaker. Holland was not prepared sufficiently to support his attacks on the southern Netherlands and also regarded with aversion the dynastic policies that he was pursuing. In 1641 Frederick Henry succeeded in marrying his 14-year-old son, later prince of Orange as William II, to Mary, daughter of Charles I of England—a marriage which enhanced the glory of his house but laid on him the burden of supporting the English king in his domestic conflicts. Holland insisted on making peace as soon as possible, and when Frederick Henry died on March 14, 1647, the peace negotiations, started against his wishes in 1646, were about to lead to results. On Jan. 30, 1648, the Dutch and the Spaniards signed the peace of Münster; since the French remained at war with Spain the Dutch signature to this peace was a clear violation of the treaty of 1635. The peace of Münster confirmed the settlement of 1609 and extended it insofar as the Dutch were allowed to keep the border districts of Flanders, Brabant and Limburg which they had conquered in the recent warfare and which were then known as the Generality lands (being under the authority of the states-general, without separate representation as provinces). The Scheldt moreover was to be kept closed. The Spanish king had at last recognized Dutch independence.

William II of Orange.—Frederick Henry was succeeded in all his offices and dignities by his son William II of Orange, an able young man whose dynastic and military ambitions brought him into a grave conflict with the republican and pacific rulers of Holland. He seems to have intended to start a new war against Spain on France's side and, after forcing Philip IV of Spain into peace with Louis XIV, to intervene, in conjunction with France, in the English Civil War on behalf of the Stuarts; but the issue which actually brought the republic to the verge of civil war was of a more limited nature. Holland wanted in 1649 to reduce the army further, but William II and the states-general refused. After long but fruitless negotiations Holland simply dismissed a number of commanders of companies which were paid out of Holland's contribution to the states-general (June 4, 1650). The next day William II had himself ordered by the states-general "to prevent disturbances," but Holland refused to submit. At the end of July the stadholder put six leading members of the estates of Holland into prison and marched his troops on Amsterdam. Warned in time, Amsterdam was not taken but accepted a compromise, and the six prisoners were set free. It is doubtful whether this solution could have lasted, but William II suddenly died of smallpox on Nov. 6, 1650. Eight days later, on Nov. 14 (new style; 4, old style), his son William III of Orange was born.

First Stadholderless Period.—The years from 1651 to 1672 are generally called the "first stadholderless period." The term is misleading in two respects: (1) because though Holland, Zeeland, Utrecht, Gelderland and Overijssel did not appoint a stadholder during these years, Friesland and Groningen did appoint one; and (2) because the term may be wrongly taken as implying that a government without a stadholder was abnormal. In fact, the provinces were certainly allowed not to appoint a stadholder: if 1588 be taken as the beginning of the republic as an independent state and 1795 as its end, it can be shown that, out of 207 years, in no less than 67 years some important provinces were stadholderless. Nevertheless, in 1650 the decision of five provinces not to appoint a successor to William II and not to make any arrangements concerning his son was unprecedented. It is to be explained by the fear which William II's policies had aroused and by the idea that a stadholder was essentially a military leader and thus superfluous in peacetime.

Holland made an attempt to lay the foundation for a new form of government by summoning to The Hague the so-called grand assembly (Jan.–Aug. 1651), which, although composed in the same way as the states-general, was to have power to work out a new constitution. But as the other provinces refused to authorize their deputies to take binding decisions the assembly was just as weak as the states-general and no new constitutional rules were defined. Actual power then reverted to the ruling urban oligarchies of Holland, whose leading statesman, Johan de Witt (*q.v.*), was appointed grand pensionary of Holland in 1653 and remained in office until 1672. A highly cultured man with a keen scientific mind, an excellent mathematician, well-read in the classics and supported by original political theorists of whom Spinoza is the best-known, De Witt yet pursued conservative policies designed to maintain, not to increase, the economic power and political influence of the republic. Two closely related factors threatened his system and finally wrecked it: English hostility and the house of Orange.

The first Anglo-Dutch War (May 1652–April 1654; *see also* DUTCH WARS for the naval wars with England discussed below) was caused by economic and colonial rivalry and by the English Commonwealth's distrust of the influence which the Orangist party in the Netherlands, closely linked with the interests of the deposed Stuart dynasty, was apparently still exercising. It was a naval war in which the Dutch, although led by such distinguished commanders as Maarten Tromp and Michiel de Ruyter, finally had to yield. Oliver Cromwell, however, then protector of the Commonwealth, was averse to continuing the war against a Protestant republic and

concluded the treaty of Westminster (April 1654) on the understanding that the Dutch would pay compensation for damage to English commercial interests overseas and would guarantee that the prince of Orange should never again be in a position to further the Stuart cause. As De Witt would not ask the states-general to bar the house of Orange, only the estates of Holland passed the so-called Act of Seclusion (May 4, 1654), which excluded the prince of Orange from the office of stadholder of Holland.

Thereafter Dutch foreign policy was more successful. De Witt intervened in the Danish-Swedish war of 1657–60 and brought about a settlement which secured the safety of the Baltic trade. The restoration of Charles II to the English throne in 1660 had no immediate effect on Dutch domestic policy, though the estates of Holland repealed the Act of Seclusion. As Charles was unwilling to conclude an alliance with the republic, De Witt established more friendly relations with France (alliance of 1662). Then, after attacks by the English Africa company on Dutch possessions in west Africa and in North America (New Netherland with New Amsterdam), a second Anglo-Dutch war was officially declared in 1665. This was purely a commercial war in which the Dutch had the upper hand. The French supported their allies against the bishop of Münster, Bernhard von Galen, who as an ally of England attacked the eastern provinces. Peace negotiations, opened at Breda in April 1667, proceeded rapidly after the Dutch raid on the Medway (June), and the peace of Breda, concluded on July 31 (N.S.) was a compromise: New Netherland was ceded to England; Surinam (central Guiana) and Run (Pulau Run in the Banda islands) went to the Dutch.

Meanwhile Louis XIV of France had begun his War of Devolution by invading the Spanish Netherlands in May 1667. This threat to the security of the United Provinces gave Charles II of England an opportunity of breaking the Franco-Dutch alliance. He left De Witt no choice but to sign an anti-French alliance with England which became a triple alliance on Sweden's accession to it (1668). Charles however very soon turned to Louis XIV for subsidies and in 1670 concluded the secret treaty of Dover (*q.v.*), whereupon both kings prepared for a decisive blow against the completely isolated republic. In the face of this threat, William III of Orange was in Feb. 1672 provisionally appointed captain-general for one campaign. In March and April the two kings declared war; and in June a magnificent French army under Louis XIV himself occupied the greater part of the republic, though it did not enter Holland. Then, in July, William of Orange was appointed stadholder by Zeeland and Holland and full captain- and admiral-general of the union. Irresistible popular movements forced the oligarchs to give him all the rights and offices of his ancestors. On Aug. 20, just after having resigned his office of grand pensionary, De Witt was murdered at The Hague by an Orangist mob.

William III of Orange.—One of the first decisions of the new stadholder was his refusal of the humiliating peace terms offered by England and France. Louis XIV did not succeed in conquering Holland; the Dutch fleet maintained its supremacy over the English navy in a series of battles. In 1674 Charles II had to make peace: the treaty of Westminster, concluded on Feb. 19 (N.S.), was based on the *status quo ante bellum* but secured recognition by the Dutch of British sovereignty in the narrow seas (straits between Great Britain, Ireland and France). Anglo-Dutch relations were to be improved further when William married Mary, the elder daughter of Charles's heir presumptive, James, duke of York (1677). Meanwhile Spain and Austria had allied themselves with the Dutch in 1673, and Brandenburg and Denmark were also supporting them in the continuing war against the French, who in 1674 had to withdraw from all the republic's territory except Maastricht. No decisive battles, however, were fought, and the peace treaties of Nijmegen (1678–79) were advantageous both for the Dutch and for France. The Franco-Dutch treaty was signed on Aug. 10, 1678.

From 1678 to 1685 William found support for his anti-French policy neither in the republic nor among the other powers. But after 1685 resistance to Louis XIV's aggressive designs grew again, and in 1688, with the backing of the states-general, William set off on the expedition that won him the English crown in 1689 (*see* WILLIAM III). Thenceforward he became the leader of the coalition against French imperialism (*see* GRAND ALLIANCE, WAR OF THE). His policy, though it was essential for the safety of the republic, in the long run exhausted the republic's reserves and forced it to concentrate so exclusively on the war on land that it neglected its fleet and let England's sea power eclipse its own. William's domestic policy was moreover designed only to secure for himself the power and the money that his expensive foreign policy required. To this end he often resorted to unscrupulous practices, including corruption. The internal situation of the Netherlands deteriorated, and the republic, while still performing tasks of great international importance, was on the decline.

Second Stadholderless Period.—William III died childless on March 19 (N.S.; 8, O.S.), 1702. His nephew, John William Friso, stadholder of Friesland and Groningen, was a minor, and the five other provinces were not prepared to appoint him. Thus once again the majority of the provinces remained stadholderless. Power reverted to the urban oligarchies and their representative, the grand pensionary of Holland, Antonius Heinsius (*q.v.*). Heinsius continued the foreign policy of William III. During the War of the Spanish Succession (*q.v.*), the republic acted for the last time as one of the great powers, bore the brunt of the fighting and maintained a large army; but Heinsius was unable to compete with Great Britain's diplomatic superiority and resigned himself to signing the treaty of Utrecht in 1713. This treaty, it was thought in Holland, gave England the fruits of the victory won by the Dutch. The only concrete gain was the right to maintain a military barrier (*see* BARRIER TREATY) against France in the southern Netherlands—which moreover were to be transferred from Spanish to Austrian sovereignty. But as French policies changed and the Dutch generally neglected their defenses, the barrier never served a useful purpose.

From 1713 Heinsius sought to avoid international commitments. The states-general subscribed to the conservative triple alliance with Great Britain and France in 1717 but kept out of the ensuing diplomatic conflicts. After Heinsius' death (1720) one of his successors, Simon van Slingelandt, grand pensionary from 1727 to 1736, took action when the East India company, which had been established by the Austrians at Ostend in 1722 (*see* OSTEND COMPANY), threatened Dutch economic supremacy in the southern Netherlands as well as in India: in collaboration with Great Britain and France he secured its dissolution in 1731. During the War of the Austrian Succession (*q.v.*) the republic, despite its alliance with Great Britain and Austria, tried to stay out of the fighting as long as possible, even after the French had taken many of the Dutch barrier towns (1744), won the battle of Fontenoy, captured the rest of the barrier (1745) and conquered nearly all of the Austrian Netherlands (1746). In April 1747, however, the French invaded Dutch Flanders; they had no intention of conquering the republic, but merely wanted to force it to make peace officially. Reminiscences of 1672 then brought about a complete change.

The internal situation had gradually been deteriorating: the treasury of the union was exhausted; taxes in the provinces, especially in Holland, were extraordinarily high but were farmed out and did not yield enough; and the navy and army were neglected. A grand assembly, convened in 1716, had broken up in 1717 without having been able to improve the constitution, and the rule of the patrician families had degenerated to a narrow oligarchy which shamelessly abused its position to increase its wealth. From about 1730, moreover, the Dutch economy had begun to stagnate: the tendency to specialize in financial transactions rather than in the carrying trade, growing competition from British and French industries and the decline of the Amsterdam staple market together led to increasing unemployment on the one hand and to the increasing wealth of a few capitalists on the other. The republic was still a rich country, but its wealth was less equally divided than in the 17th century. In economic power, no longer supreme in Europe, it was to cede the first place to Great Britain and the second to France before the end of the 18th century. Politically it was already virtually powerless when the French invasion of

1747 aroused for a moment the old passions.

William IV of Orange.—John William Friso's posthumous son William IV of Orange, stadholder of Friesland from 1711, of Groningen from 1718 and of Gelderland from 1722 and the husband of George II of England's eldest daughter Anne from 1734, was in April–May 1747 elevated to the stadholdership of all the other provinces and made captain- and admiral-general of the union. His power was greater than that of any of his predecessors but he was completely incapable of using it. He was unsuccessful as a general, did nothing to improve the Dutch defenses and was quite unequal to the task of improving the constitution and the financial system and of bringing about the reforms needed in order to grant some influence in local and provincial government to larger groups of the population. By making it clear that only substantial British military and financial support could prevent the republic from falling into French hands, William IV obliged the British, who had wanted to continue the war, to sign the peace of Aix-la-Chapelle in 1748.

William V of Orange and the Patriots.—On his death in 1751 William IV was succeeded as stadholder by his three-year-old son William V. During the latter's minority his mother (until her death in 1759) and then the provincial estates acted as regents. They maintained Dutch neutrality during the Seven Years' War—a policy which was highly profitable commercially. In 1766 William V was declared of age. The last of the stadholders, he was the least able of them. His excessive conservatism made him use his great power exclusively to perpetuate the existing constitutional paralysis and to protect the oligarchy against increasing resistance, but his identification with the interests of the ruling classes did not make him acceptable even to them. He was unable to strengthen the army and navy, though he did his best to carry out some reforms in this field. The few reasonable decisions that he took were inspired by his intelligent and spirited wife, Wilhelmina of Prussia, whom he distrusted because of her will power.

William's incompetence and the Anglophile policy that he pursued brought about a fundamental change in the structure of the Dutch political parties. Traditionally the prince of Orange found support among all classes except the patrician oligarchy and was regarded by the lower middle classes and the workmen as a counterpoise to the urban aristocracy. But as the revolution of 1747 had not brought about any reform, the bourgeoisie gradually lost confidence in the stadholder's ability to introduce a more democratic system of government. Moreover the close connection with England was becoming distasteful to large sections of the population which thought British expansion overseas just as intolerable as Louis XIV's megalomania and rejoiced at seeing it beaten by the American Revolution. For the first time in Dutch history nationalistic feelings, caused by frustration and despair about the decline of the republic, gave rise to a new party.

This was the Patriot party. As yet it was not properly constituted, but the men who later became its leaders helped the oligarchs to undermine William V's authority. They were jubilant when in 1780 Great Britain, refusing any longer to tolerate the highly profitable carrying trade of the Dutch merchants with America and France, declared war on the republic. But the British blockaded the Dutch coast and captured Dutch colonies, and the Dutch economy received blows from which it never recovered. During the negotiations preceding the peace of Paris (the Anglo-Dutch treaty was signed in May 1784) France hardly supported the states-general, who had to cede Nagapatinam in southern India to the British and to grant them the right of navigating through the Moluccas. Denounced by the Patriot movement for his political mistakes, for his lack of energy and for his inability or perhaps unwillingness to beat Great Britain, William V left The Hague in anger in 1785. Thenceforward democratic movements sprang up everywhere, but mainly in Utrecht and in Holland, and the power of the oligarchies was broken in several towns. It is remarkable that the Patriots, although partly democrats and all of them supporters of the French alliance, were influenced by English rather than by French political theories. What really inspired them, however, was not abstract ideology but the desire to reform the system of government in a supposedly conservative way through the restoration of those democratic practices which, it was thought, the stadholders and the regents had nullified.

In 1787 the development of the Patriot party was suddenly stopped. The king of Prussia, Frederick William II, on the pretext of an insult offered to his sister Princess Wilhelmina, sent an army which met no resistance and brought the stadholder back to The Hague—to the great relief of the British ambassador, Sir James Harris (afterward 1st earl of Malmesbury). Thousands of Patriots found refuge in France.

End of the Old Republic.—The restored Orangist regime was rootless and was effectively opposed by the great banking houses, which refused loans. It was unable to strengthen the army and could hardly put up any resistance when in Jan. 1795 the French revolutionaries, who had declared war on the stadholder in 1793, invaded the republic. It was thus the army of Gen. Charles Pichegru that brought the revolution for which the Patriots had been hoping since 1787. (*See* FRENCH REVOLUTIONARY WARS.)

In May 1795 Franco-Dutch relations were defined in a treaty according to which the Dutch were to pay 100,000,000 guilders, to cede some territory and to allow the French to occupy some important fortresses. A treaty of alliance was concluded at the same time, bringing the Dutch into war against Great Britain. In the following years the British conquered all the Dutch colonies, and the war dealt another serious blow to the shattered economy. Nevertheless, plans for thorough reforms were made in an atmosphere of great rejoicing and hope. A national assembly was elected (1796) and charged to draft a new constitution, but was frustrated by the paralyzing conflicts between the radical "unitarians" and the moderate "federalists." A series of *coups d'état* supported by France led to the institution of a new form of government (April 1798).

D. Batavian Republic and the Napoleonic Regimes

The new regime of 1798, officially called the Batavian Republic, was modeled on that of the Directory in France. It was regarded with indifference by a population now gravely suffering from the economic slump: in many towns one-third or even one-half of the inhabitants depended on charity. Then, in Oct. 1801, at the behest of Napoleon Bonaparte, then first consul of the French Republic, a more conservative government was set up, in which some Orangists were allowed to take part. This prepared the way for the reconciliation of the old political parties, oligarchs and Orangists. In March 1805 the system of government was changed once more, the Batavian Republic was renamed Batavian Commonwealth, and executive power was given to a kind of dictator called the council pensionary. Rutger Jan Schimmelpenninck, who was appointed to that function, was an extremely able man and carried out many overdue and lasting reforms. Very soon, however, in June 1806, the Batavian Commonwealth had to make place for the Kingdom of Holland under Napoleon's brother Louis (*see* BONAPARTE). This monarchy lasted until July 1810, when Holland was incorporated into Napoleon's French empire and divided into *départements:* Bouches-du-Rhin, Deux-Nèthes (these two including some Belgian territory), Bouches-de-l'Escaut, Bouches-de-la-Meuse, Zuiderzee, Yssel-Supérieur, Bouches-de-l'Yssel, Frise and Ems-Occidental. When news of Napoleon's defeat in the battle of Leipzig reached Holland at the end of Oct. 1813 a national revolt broke out, which immediately called for the return from exile of the prince of Orange, William V's son William VI. He was to return, however, not as stadholder but as sovereign prince.

(E. H. K.)

E. Kingdom of the Netherlands

William I.—It was only after some hesitation that the prince of Orange, in Dec. 1813, accepted the title of sovereign prince of the Netherlands, for he disliked the popular origin of his new sovereignty. He was inaugurated (without any coronation) in Amsterdam on March 30, 1814, by an assembly of notables who on the day before had approved the first written constitution of the state. This fundamental law retained many institutions of the French period and established a constitutional monarchy and a centralized state with a single legislature, uniformity in adminis-

tration, justice, finance and the fiscal system and legal equality for all recognized creeds. The one-chamber parliament kept the old name of states-general and was elected by indirect vote, representing only the upper and upper-middle classes. It had very limited rights, and the sovereign, whose progressive economic policy could not win a majority in it, was in fact to bypass it as much as possible and to govern mainly by orders in council, as the ministers were responsible to him only.

In July 1814 William undertook the provisional government of the southern Belgic provinces of the Netherlands, which the Austrians had lost to the French Revolutionary armies in 1794 and which the European powers were intending to transfer, together with the former bishopric of Liège, to the sovereign principality. The congress of Vienna, however, had not yet ratified the transfer when William, on March 16, 1815, at the news of Napoleon's return to France from Elba, proclaimed himself king of the Netherlands. The congress soon confirmed the creation of the new kingdom, with its increased territory; and in Aug. 1815 a new fundamental law came into force. The principles of the new law remained as firmly monarchical as those of 1814, but the states-general then consisted of two chambers and the seat of the government was to alternate yearly between The Hague and Brussels. Moreover, in exchange for his hereditary territories in Germany, William received Luxembourg as a grand duchy. Though the kingdom and the grand duchy were in personal union only, William proceeded to treat Luxembourg (a member of the German confederation) as a Dutch province.

The kingdom of the united Netherlands was launched in very difficult circumstances. While Europe in general was undergoing an economic crisis, there was a clash of interests within the kingdom between the predominantly commercial north and the highly industrialized south. Also the clergy and the ruling class of the *ancien régime* resented the new state's system of religious and political equality. Nevertheless the king, dedicating himself to the task of government, tried to give a sound basis to the union through a policy of economic welfare. These very endeavours vexed the north, which clung to the archaic system of free staple-trade and found its spokesman in G. K. van Hogendorp, to whose activities at the end of the French period the king owed his throne. Through new institutions such as the General company (1822) and the Netherlands Trading company (1824) the king promoted industry and commerce, including colonial trade.

Later Dutch historians (P. Geyl, C. Gerretson and L. Verberne) have stressed this positive side of William's reign as a real contribution to the viability of the new state. they point to his care for agriculture, in which north and south alike were interested on a large scale, and to the important economic recovery made by the whole country. They also stress the fact that the kingdom's manifest difficulties cannot all be attributed to the generally overstressed opposition between the so-called Calvinistic northern and Catholic southern parts of the country: there were numerous Roman Catholics in the north as well as in the south; and the language decrees of 1819 and 1822, favouring Dutch as opposed to French as the official language, were in force only in the Flemish regions, where they served to strengthen national feelings among the lower classes.

These so-called "Great Netherlands" historians regard the Belgian revolution of 1830 as the second rupture (after the split between north and south in the 16th century) in what ought to be a whole. They offer a useful corrective to the "Belgicist" and "Little Netherlands" historians in whose opinion the kingdom of the united Netherlands had no chance of survival and the emergence of the Belgian nation was inevitable. The kingdom set up by the congress of Vienna was a somewhat artificial creation, but its disastrous end was brought about mainly by misconceptions and by the narrow self-interest of the various groups, both in the north and in the south, combined with the effect of tactless and presumptuous measures taken by the king.

It was William I's great misfortune that two parties of the south which had originally opposed one another joined hands in 1828 in a common resistance to his meddlesome and autocratic government: the Roman Catholics, shifting under the influence of the French *abbé* Hugues Félicité Robert de Lamennais toward a sort of Liberal Catholicism, and the Liberals, eager to achieve ministerial responsibility and similar reforms. At first the Belgian rebels of 1830 (*see* BELGIUM: *History*) did not aim at an independent Belgian state and might have been satisfied with a redress of grievances, but hesitations and tactless measures by the king and his government, together with revolutionary influences from France, brought about the rapid disintegration of the Netherlands union. The Flemish provinces followed the rebellion of Brussels reluctantly and only after the government had suffered reverses, while Dutch public opinion on the whole welcomed the breakup of the union. Yet even after the great powers had recognized Belgian independence (1831–32) and had forced the Dutch to renounce hostilities (Convention of London, May 1833), the king persisted in refusing to accept the conditions of the separation till 1838. Meanwhile the Belgians remained in occupation of Luxembourg and Limburg (except Maastricht) and the Dutch had to maintain large forces in case war should break out again. This strained the Dutch finances more and more, but the king's secret "amortization syndicate" enabled him to withhold the administration of public money from parliamentary control. Also the so-called "plantation" or "cultures" system, which guaranteed to the government large quantities of East Indian agricultural produce obtained by forced labour, prevented an immediate public bankruptcy. On the whole the financial policy of this "merchant-king" must be considered the dark side of his courageous and far-seeing economic projects. Under the settlement of 1839 between the Netherlands and Belgium (treaty of London) part of Limburg was restored to the Dutch, while the Belgians retained part of Luxembourg.

The Belgian revolution and its repercussions brought a resurgence of national sentiment to the Dutch people: the diminished Netherlands kingdom began to awake from its religious, cultural and political apathy. In 1834 a group of orthodox Calvinists, the Separatists, seceded from the Dutch Reformed Church, whose "liberal" and "enlightened" spirit corresponded to William's Erastian ideas of enlightened absolutism. The foundation of the monthly *De Gids* by E. J. Potgieter and R. C. Bakhuizen van den Brink in 1837 signified a literary revival of a rationalistic and liberal character, whereas the religious and literary movement known as the "Reveil," with G. Groen van Prinsterer as one of its leaders, represented the romantic conservatism of the Restoration. The nation was definitely turning away from the ideas which King William I personified, and in 1840, as a result of increasing opposition by the Liberals, the constitution was revised. Though this revision was by no means radical and greatly disappointed the Liberals, to the king it meant the end of his reign. He abdicated voluntarily a few weeks afterward (Oct. 7, 1840), in favour of his son.

William II.—During William II's reign (1840–49) the liberal trend gathered strength while the new king, at first mildly progressive, gravitated more and more toward conservatism. His minister F. A. van Hall succeeded in stabilizing the public finances. The king, whose Belgian experiences had contributed to his good relations with Roman Catholics, won the good will of that community by revoking some restrictive decrees that his father had passed; and the Calvinist Separatists were also treated more leniently. The Liberals grew more and more discontented, but the largely conservative second chamber rejected without discussion a motion sponsored by J. R. Thorbecke (*q.v.*) and eight other Liberal members for the revision of the constitution (1844). Meanwhile, signs of a social disturbance in the Netherlands were discernible during the "hungry forties," when more than one-third of the population had to receive outside relief. These signs were exploited by former friends of the capricious king in their criticism of him, which moreover was made easier by his own personal behaviour. Finally, under the influence of revolutionary events in France and Germany, the king in March 1848 made a characteristic *volte-face:* bypassing his cabinet and the majority in parliament, he convened a commission of convinced Liberals, who, under Thorbecke's direction, drew up a new constitution. It was accepted that very year by parliament.

The constitution of 1848 established the inviolability of the sovereign; ministerial responsibility; direct elections to the second chamber, to the provincial estates and to municipal councils; an extension of the power of parliament; and new or enlarged rights of free assembly and public meeting, education and religion. William II, who was said to have turned from a conservative into a Liberal within 24 hours, died a year later, on March 17, 1849, and was succeeded by his eldest son.

William III.—William III, though he did not sympathize with the new constitution, bowed unwillingly to the changed circumstances. After some hesitation he appointed Thorbecke, whom he came near to hating, as his principal minister. Thorbecke consolidated the constitution: he drafted important organic laws regulating the electoral system and the provincial and municipal administrations. In April 1853, however, when a Protestant deputation presented a petition against Pope Pius IX's restoration of the Roman Catholic hierarchy in the Netherlands, the king, against Thorbecke's advice, addressed it in terms derogatory to Catholics. The second chamber approved Thorbecke's attitude, but Thorbecke nevertheless resigned. The episode exemplified the personal authority of the king, who in fact, after Thorbecke's second ministry (1862–66), was to rule through his cabinet without or against parliamentary majorities till 1868. Thereafter no Dutch ministry ignored parliamentary disapproval, though the king's influence could still be considerable whenever there was no working majority in parliament.

Political Clubs and Parties.—In the time of Thorbecke, who formed his third and last cabinet in 1871, there were no political parties in the proper sense but only "clubs" in the second chamber, backed at best by embryonic electoral organizations in the country. The political movements vaguely represented in these clubs were: (1) the Liberals led by the typical "lone-wolf" Thorbecke, who was adverse to political parties; (2) the Conservative Liberals, who did not constitute a club as such and whose most prominent spokesman, F. A. van Hall, headed the cabinet twice (1853–57 and 1860–61) between Thorbecke's first and second ministry; (3) the Conservatives proper, who opposed the constitution of 1848 and represented a diminishing reactionary minority but enjoyed the king's sympathy; and (4) the increasing group of "Antirevolutionaries," who under Groen van Prinsterer's leadership were developing from a position close to the Conservatives into a constructive and efficient political body with orthodox Protestant principles and were recruiting most of their followers from among "the people behind the electorate," namely, the classes not yet enfranchised. The Roman Catholics (about one-third of the population) long failed to constitute a club of their own and adhered partly to the Conservative Liberals, partly to the Liberals.

About 1870 the Conservative Liberals merged with the dwindling Conservatives, but this combination, in which Jan Heemskerk played a leading part in the 1870s and '80s, did not establish an effective political organization and eventually disappeared. The first political party proper was the Antirevolutionary party, founded in 1878 by Abraham Kuyper (*q.v.*). Though after Thorbecke's death (1872) the "Young Liberals," including Samuel van Houten, J. Kappeyne van de Coppello and Hendrik Goeman Borgesius, won influence in government circles, the Liberals as a whole were too much divided to achieve an efficient organization: the "Liberal union" of 1885 united only a minority of them. The Roman Catholics, who by this time had formed their own parliamentary club, could not yet be induced to form a political party: the attempts of Herman Schaepman in this direction were unsuccessful—not least because of dissension on such problems as the extension of the franchise and collaboration with the Calvinists. At the end of William III's reign the Socialists had one seat in the second chamber and their political organization was only in a provisional stage.

The Education Question and the Coalition Ministry of 1888–91.—The question of education gradually became a dominant factor in Dutch politics. The constitution of 1848 had given freedom of teaching but made the government responsible for public elementary instruction; and the Education act of 1857 had laid down that the public elementary school was to educate the child in "all Christian and social virtues." It was hoped that this provision would meet the objections of the orthodox to the nondenominational, or, as they said, "godless" state schools. It did nothing of the sort, however, and, when in 1878 the Liberals under Kappeyne van de Coppello revised the act of 1857 without making any concessions to religious scruples, the agitation gathered strength. The Roman Catholics, who had benefited from the constitution of 1848 and had long supported a more or less liberal policy, began to desert the Liberals. Both orthodox Calvinists and Catholics maintained that it was unfair to make people pay for the upkeep of nondenominational state schools when conscience required them to send their children to private denominational ones instead; but their demand—that the state should give financial support to private denominational schools as well as to the nondenominational ones—was strenuously resisted by the Liberals, who regarded denominational schools as seedbeds of national disruption and invoked the constitution against the demand.

In 1887 the constitution was changed to permit an extension of the franchise. This more than doubled the electorate, raising it to about 300,000, with the result that the Liberals—divided as they were among themselves—had to give way to the representatives of the lower classes. The first coalition ministry between the Antirevolutionaries and the Roman Catholics (1888–91), of which the Calvinist Aeneas Baron Mackay was the head and the Catholic Schaepman the mainspring, was an entirely unprecedented combination which indeed owed its existence chiefly to reaction against the education policy of the Liberals. After an attempt to introduce the possibility of state support for private denominational schools into the revision (1887) of the constitution had been defeated by the first chamber, the government took the view that such support need not be regarded as unconstitutional; and in 1889 a new Education act brought the first modest subsidies for denominational schools. The dominance of the Liberals was already diminishing when William III died on Nov. 23, 1890.

Economic and Social Development, 1849–90.—Not only in political matters was William III's reign the heyday of liberalism—despite the king's own preferences. Following the English example, Thorbecke during his first ministry had introduced navigation acts to facilitate international commerce; and in 1862 free trade was initiated. In the 1860s likewise a number of excise duties were abolished. On the other hand it was the state which built the railways to be exploited by private concerns (1860). Thorbecke's second ministry sponsored the construction of the North Sea canal linking Amsterdam to IJmuiden (completed 1876) and of the Nieuwe Waterweg (New waterway) from Rotterdam to Hook of Holland (completed 1871). Thorbecke was also the founder of the polytechnic school at Delft and of the burgher high school, a new type of secondary school for the middle classes.

The "cultures" system, surviving in the colonies from William I's time, was attacked both because of the hardship that it inflicted on the indigenous population and because it contradicted liberal economic theory: free labour was advocated in the interests of the Javanese workers and the Dutch capitalists alike. On this point, however, Thorbecke did not agree with his more radical minister for the colonies, I. D. Fransen van de Putte; and it was not until 1870 that the system was abolished for all crops except coffee, government plantations of which were maintained for some more decades.

At the same time the methods of modern capitalism were applied to the textile industry in Twente and North Brabant and to the steel industry. The pulse of industrial life was quickening in the '70s and '80s, but the lack of sufficient capital still retarded the progress of the "industrial revolution."

Social legislation was likewise late in development. The first law against child labour was passed in 1874 and was not very effective, but in 1889 the coalition ministry put greater restrictions on the employment of women and children. From the late 1860s trade unions were springing up, but the general Netherlands Workmen's association of 1871 was inspired by liberal ideas and patronized by the employers. The orthodox Calvinist labourers seceded from the association and formed a trade union of their own, Patrimonium, in 1876.

The Socialists' first national labour organization was the Soci

Democratic union (1881), a body also politically active under the leadership of the ex-pastor Ferdinand Domela Nieuwenhuis, a spectacular fighter who was put in prison for some months for *lèse-majesté* (he was prosecuted for publishing an article disrespectful of the king). The Roman Catholics began to form unions about 1889, inspired by the priest Alphons Ariëns.

(H. A. Bo.)

Accession of Queen Wilhelmina.—With William III the male line of the house of Orange-Nassau became extinct, so that on his death the kingdom of the Netherlands passed to his daughter Wilhelmina (*q.v.*). The personal union between the Netherlands and Luxembourg, however, was then ended, as the grand duchy reverted to the ducal house of Nassau-Weilburg.

The new queen was only ten years old in 1890. Consequently her mother, Emma of Waldeck-Pyrmont, whom William III had married as his second wife in 1879, acted as regent till Wilhelmina came of age on Aug. 31, 1898. Wilhelmina was married in 1901 to Henry, duke of Mecklenburg-Schwerin, and a daughter, Juliana, was born in 1909. Thus the house of Orange, surviving only in a female line and confronted with republican sentiments in the parties of the left, came gradually to consolidate itself as the constitutional power envisaged by the Liberals of 1848; *i.e.*, as a monarchy that would exert its authority mainly in times of cabinet crisis.

Internal Affairs, 1890–1913.—In the opening period of Wilhelmina's reign cabinets remained regularly in office for the four years between elections to the second chamber. The only break in this regularity occurred between the elections of 1905 and those of 1909, when Theodoor de Meester's government had to be replaced by a coalition after less than three years of office. This governmental regularity, however, did not mean that political life developed on regular lines.

The Dutch economy was slowly reviving. From the 1870s Amsterdam and Rotterdam had both had direct access to the North sea, and their trade was benefiting from a twofold stream of products: (1) from the Netherlands East Indies, freely exploited by international capital; and (2) from the big new German industries of the Ruhr. By the later 1890s, moreover, agriculture, which had undergone a great crisis in 1885, was prospering because of modern methods of production and distribution, in which the farmers' cooperatives played a conspicuous part (mostly concentrating on dairy produce). At the same time larger firms grew up in the textile and shipbuilding industries, attracting many more people to the towns and greatly increasing the number of unskilled workers. Some industries even emerged from the beginning in the form of large producing and exporting units, spanning the whole world and sometimes working in combination with British firms; *e.g.*, margarine (Van den Bergh), petroleum (Royal Dutch) and electric apparatus (Philips). These developments promoted the growth of organized labour on the one hand and the large-scale integration of finance, trade and industry on the other.

A simultaneous revival can likewise be traced both in the arts (literature, painting and architecture) and in the life of the most important religious groups. In the latter case this revival had a bearing on politics. The Roman Catholic population, which constituted a large minority in the western cities and an overwhelming majority in the southern areas, had begun to take political action as a distinct force on its own account in the 1880s, under the powerful spell of Schaepman. Despite strong opposition from other politicians on the Roman Catholic side, Schaepman sought not only to collaborate with the Calvinists in the struggle for private schools but also to promote the formation of Roman Catholic trade unions in accordance with Pope Leo XIII's encyclical *Rerum Novarum* (1891). These Catholic unions organized themselves on a nationwide scale in 1909.

Trade unionism played its role also in the Calvinistic north, where Abraham Kuyper likewise worked for democratic reforms. Yet, though Kuyper took the chair at the first Christian-Social congress in 1891 in order to arrange terms between his party and the Protestant workers, no really effective Calvinist trade union came into being until 1909. Kuyper, however, combined a progressive social policy with insistence on Calvinist orthodoxy, and the result was a double schism in the Calvinist ranks: already in 1886 he had seceded from the Dutch Reformed Church, which he accused of yielding to heterodox opinions of a few; and finally, in 1897 he had forced the right wing of his own Antirevolutionary party to split off from the majority. This right wing formed a party of its own, the Christian Historical union, led by A. F. de Savornin Lohman.

Meanwhile the nascent socialist movement was being penetrated by a number of atheist intellectuals, who gave it a revolutionary, republican and anticlerical slant, with a strong tendency to anarchism. This individualistic and anarchist trend effected the Social Democratic union under Nieuwenhuis; and to counter it the parliamentarians and Marxists under Pieter Jelles Troelstra set up a new Social Democratic Labour party, which practically ousted the Social Democratic union after 1900 and founded its own trade union organization in 1906. Both forms of socialism, however, had some affinity with bourgeois liberalism in their intellectual attitude, which alienated both Kuyper's Calvinistic "small people" and the Roman Catholics.

The first coalition government of Roman Catholics and Calvinists (1888–91; *see* above) had marked the end of an era in which Liberal or Conservative Liberal groupings had been supreme in Dutch public life; though there were Liberal governments in the succeeding decade to 1901 (the "last ten Liberal years") the Liberals were too much divided among themselves to reverse the new course of affairs. Moreover the advent of the coalition had shown that the political system could no longer be built only upon the parliamentary groups: the organization of the masses became important. With this development the question of universal suffrage came to the forefront. When the Liberal minister J. P. R. Tak van Poortvliet proposed in 1894 to extend the franchise to nearly general suffrage, he raised an issue that was to test the coherence of the various parties severely. The Liberals, indeed, were eventually to be split into three sections: the conservative section, against Tak; the radical section, for Tak; and finally the strong radical wing under M. W. F. Treub, who as an alderman in Amsterdam was working out a program of his own, municipalizing the telephone service and the water supply (previously run by private companies). After a limited extension of the franchise, raising the electorate to about 700,000, had been enacted in 1896, the Christian parties and the majority of the Liberals were more or less satisfied; but Treub's adherents continued to stand for universal suffrage and, in 1901, formed a party of their own, as Liberal Democrats. The Socialists also concentrated their activities on the campaign for universal suffrage, organizing huge demonstrations in 1912 and 1913. This enhanced their popularity, so that their representation in parliament rose from 2 seats in 1897 to 16 in 1913 (out of 100). The Roman Catholics, who had had 25 seats in 1888 but only 17 in 1905, had 25 again in 1913; but Kuyper's Antirevolutionaries fell from 25 seats (1888) to 11 (1913), while the Christian Historicals rose from 6 (1897) to 10. The Liberal representation slowly declined from 46 in 1888 to 38 in 1913 (only in 1905 increased to 55).

N. G. Pierson's cabinet of 1897–1901 was important for the social legislation that it inaugurated. This extension of governmental activity was to remain characteristic of the next decades: the Christian parties supported it against the Conservative Liberals, while the Social Democrats for the most part stood critically aloof. When the government in 1898 proposed that the state should run an insurance scheme against industrial accidents, the implicit threat of centralization caused employers to react by building up organizations of their own, and the government, failing to win a majority in parliament, had to change the bill in a decentralizing direction. The new employers' unions, however, having originally been designed to oppose the workers' unions, later came to collaborate with them. In social affairs, furthermore, a tradition grew up of endowing private institutions with some governmental executive tasks. This practice appealed to progressive Roman Catholics and Calvinists and was accepted by Socialists insofar as it did not undermine the role of the government as the final instance; but the conservative elements in the religious groups united with the Liberals in opposing it as prejudicial alike to personal liberty and to the constitution.

The period of Kuyper's ministry of Calvinists and Catholics (1901–05) was especially eventful. At home the ministry had to face the great strike movement of 1903. This started when the railwaymen, in sympathy with a strike in Amsterdam harbour, refused to handle goods from ships there: their action spread fast throughout the country and developed into pressure on the railway boards to improve labour conditions. The Kuyper government then intervened, making a political issue out of the social unrest with a bill to ban strikes of government employees as well as of railwaymen. In the face of strong Socialist opposition this bill was passed, and a new strike, intended to be a general one, broke down. Kuyper was also instrumental in settling at university level the old struggle for denominational schools: "private" universities received official recognition. The attempt of the Socialists and Liberals to take religion out of Dutch politics had failed.

Hostile to Kuyper, the Socialists backed the Liberals in the elections of 1905. There followed an extraparliamentary cabinet with a Liberal tendency under Theodoor de Meester, but this cabinet resigned in Dec. 1907. Then in Feb. 1908 the Christian coalition was brought back to office—with Theodoor Heemskerk, however, instead of Kuyper at its head. Winning 60 seats at the elections of 1909, the coalition resumed the task of social legislation and in 1910 proposed a system of social insurance chiefly for benefit of sick and aged workers. Discussions on this took up most of parliament's time till 1913.

The Policy of Neutrality and World War I.—From 1899 foreign policy became of increasing importance. A first international peace conference, convened at The Hague in 1899 by Queen Wilhelmina and the Russian emperor Nicholas II, had little effect but bore witness at least to the alarming predicament of a small country surrounded by great powers in rivalry. A reconsideration of the neutrality that the Dutch had traditionally maintained since Napoleon's time seemed to be necessary, and in 1905 the queen broached the possibility of foreign alliances in a note to the prime minister Kuyper. Apart from the embarrassment felt when the Russians had sought permission for their ships to bunker in the Netherlands East Indies during the Russo-Japanese War, it was clear that Dutch neutrality could be maintained only so long as none of the European powers attacked the Netherlands; and at this very moment the German general staff was planning to send its armies through the southern part of the Netherlands if war should break out with France.

The East Indian colonies were believed to be the object of German expansion, though as yet the island of Java was alone of major economic importance and parts of Sumatra were still only under precarious control; and the first signs of Indonesian nationalism were appearing. Consequently the new "ethical policy" for the colonies was introduced, with special emphasis on better educational facilities for the Indonesians. The export trade of the Netherlands East Indies doubled itself between 1900 and 1914 and greatly enhanced Dutch prosperity. On the other hand the German transit trade on the Dutch rivers was also a considerable source of wealth for the Netherlands, and it was undoubtedly difficult for many Dutchmen to resist the fascination of Germany's prestige, while anti-British feelings had been stimulated by sympathy for the Boers in the South African War.

Strategically and economically the country was extremely vulnerable, and the strengthening of its defenses was therefore imperative. This became, from 1911, the special concern of Hendrikus Colijn (*q.v.*). Already in 1898 universal military service had been introduced, and in 1901 the reorganization of the army had been started. The long coast line called for special attention: in 1911 a new fortress was built at Flushing. Further measures, however, could be carried out only to a limited extent in the face of objections from the Belgians, who feared the closing of the Scheldt, and from the British, who feared that such measures might eventually serve Germany's purposes.

Though commercial interests remained of importance, foreign relations became more and more subject to purely political considerations, as can be seen from the several pacts of arbitration concluded between 1904 and 1913 (Denmark, Portugal, France, Great Britain and the United States). There was a remarkable German project for a North Sea pact in 1908 to secure for Germany the benevolent neutrality of Netherlands in the event of war; but the Dutch government assented to it only after France had done so too, thus making the pact ineffectual.

When World War I broke out in 1914 the policy of neutrality was put to the test. The army was mobilized for four years and the frontiers were closed (even so, temporary homes had to be found for thousands of Belgian refugees from Antwerp and its vicinity). Commercial activity was severely restricted: the British extended the list of contraband goods by an order in council of Aug. 20, 1914, and exercised their right of search on Dutch ships; Germany declared all British waters a war area (Feb. 4, 1915), thus exposing neutral ships to the threat of torpedoing; and the Allies retaliated with a blockade of Germany which formally limited Dutch imports to the quantities estimated necessary for home consumption. Germany's declaration of unrestricted U-boat warfare in 1917 made matters even worse. When the Allies tried to charter all Dutch vessels not needed for Dutch importation, the Netherlands objected, since necessary imports for the Netherlands and for Germany alike were often carried in the same ships; then all Dutch ships in the harbours of the Allies were requisitioned by right of angary.

On various occasions it seemed likely that one or another of the belligerents would violate Dutch territory or demand such measures from the Dutch government as would provoke retaliation from the other side. In particular the question of the transit of sand and gravel from Germany across Dutch Limburg to Belgium nearly led to war: the Dutch allowed the transit of these materials for road repairs but objected to their being sent for the reinforcement of fortresses; and in 1918 the German general Erich Ludendorff wanted to take military measures to secure unrestricted use of the Dutch railways for Germany.

The extraparliamentary cabinet under the Liberal P. W. A. Cort van der Linden, in office from Aug. 1913, instituted general unemployment insurance with governmental subsidies (Aug. 1914) and took several financial measures (loans, paper money, exchange regulations, prohibition of export of gold); but neither these nor other emergency provisions, such as the Committee of National Aid, the rationing of food and fuel and a National Overseas Trading trust, were remedies against famine and epidemics prevalent during the later years of the war.

The wartime truce on which the parties had agreed in 1914 was seriously strained by the growing contrast between the economic distress of the masses and the ostentatious spending of ill-gotten riches by a handful of speculators. This contrast strengthened the tendency toward greater democratization. A far-reaching revision of the constitution was achieved in 1917: on the one hand the schools controversy was finally solved by granting state subsidies to the private schools on the same basis as to the public (mostly communal) schools; on the other, universal male suffrage was adopted, with proportional representation. The ensuing elections, held in July (1918), resulted in a clear majority for the old Calvinist-Catholic coalition, and two months later C. J. M. Ruys de Beerenbrouck formed the first cabinet in the kingdom's history to be headed by a Roman Catholic.

The Netherlands Between the Wars, 1918–40.—Though the example of the German revolution stirred the left wing of the Social Democrats under Troelstra, who seemed ready to assume power on Nov. 11, 1918, the majority of the Social Democratic party as well as of the Socialist trade unions refused to follow this revolutionary drift. Ruys de Beerenbrouck's government therefore, including as it did a new ministry for labour affairs under the Catholic P. J. M. Aalberse, remained in power to pursue a social program of its own. While the masses were demonstrating for Queen Wilhelmina and against revolutionary socialism, the old Socialist demand of the eight-hour working day was conceded—at first by private firms, before the revised labour law of 1921. A Council of Labour was set up, and the insurance laws on labour accidents and old-age pensions were renovated. Women's suffrage was established in 1919.

Three postwar problems in the international field had to be

settled: the claims to Dutch Flanders and Limburg raised by the Belgian annexationists; the victorious Allies' demand for the extradition of the German ex-emperor William II, who had fled to the Netherlands in Nov. 1918; and the Netherlands' entry into the League of Nations, which was then being organized by the Allies. The Dutch steadfastly rejected the demand for extradition but gave assurances that William II would not use his refuge in the Netherlands as a base from which to attempt to recover Germany (March 1920). Relations with Belgium, however, remained difficult, even though the Paris peace conference had dismissed the Belgian claims to Dutch territory: the Belgians still resented the sovereignty of the Netherlands over the left bank of the Scheldt estuary in the west and over part of the Meuse valley in the east. A treaty drawn up in 1920, involving concessions by the Netherlands, was signed at last in 1925, and the second chamber approved it in 1926; but after vehement popular protests it was repudiated by the first chamber in 1927.

Membership in the League of Nations, which the government regarded as a safeguard for Dutch neutrality, was represented by some of the opposition parties in the 1920s as a reason for urging disarmament. This gave rise to a long dispute, which was complicated by the rise in the government's expenditure in nonmilitary directions. Apart from the cost of its social and educational commitments, the government had to face an economic crisis (1920–23) and to find money for mining, for the railways (organized in one national company in 1920) and for air transport (first flight to Indonesia, 1923).

Colijn, leader of the Antirevolutionary party from 1922, became finance minister in Aug. 1923 in Ruys de Beerenbrouck's second cabinet (formed in Sept. 1922). A specialist on Indonesian and military affairs as well as finance, Colijn proposed a series of economy measures, mostly in the field of social welfare and education, while at the same time he wanted to build some more cruisers for Indonesian waters. He succeeded in restoring the gold basis of the gulden, but the navy bill was rejected by the combined opposition of the Socialists, the leftist Liberals and some Catholics (Oct. 1923). The government then tried to resign but was finally kept in office because no alternative government could be found. After the elections of July 1925, however, a new ministry was formed under Colijn, but it fell in the following November, when the left joined with the Christian Historicals to vote against the maintenance of a Dutch legation at the Vatican. The left correctly foresaw that this issue would terminate the Calvinist-Catholic coalition.

All subsequent governments from 1926 to 1939 were to depend for their majorities on the Liberals no less than on the confessional parties, while the Socialists remained in opposition. The distribution of the 100 seats in the second chamber was fairly constant throughout the period: after the elections of 1929, which can be taken as typical, the Roman Catholics had 30 seats, the Social Democrats 24, the Antirevolutionaries 12, the Christian Historicals 11, the right-wing Liberals 8, the left-wing Liberals 7 and the Communists 2, with 6 others. General discontent at this parliamentary stalemate, exacerbated by the world economic crisis, caused a political reorientation in the 1930s. There was revolutionary murmuring against the government's economy measures, a mutiny broke out on a ship of the East Indian navy (Feb. 1933) and, in reaction, people began looking for a "strong man." Some thought to find him in Colijn, who, after D. J. de Geer's first ministry (1926–29) and Ruys de Beerenbrouck's third (1929–33), became prime minister for the second time in May 1933 and formed three more ministries in succession (July 1935–May 1937, June 1937–June 1939 and July 25–27, 1939). His merit was that he combined democratic principles and staunch Calvinism with a Conservative Liberal approach to economics. Some extremist opinion, on the other hand, saw the "strong man" in Anton Mussert, leader of the National Socialist or Nazi movement, which for a short moment, in the provincial elections of 1935, enlisted 8% of the voters; and simultaneously the Communists gained in strength. The Social Democratic party, however, then turned away from its revolutionary, antinationalist tradition and adopted a program envisaging a welfare state: having to choose between revolution and democracy, which it had formerly regarded as virtually identical, it chose democracy. This decision was due partly to a reaction against the antidemocratic menace of fascism or national socialism at home and abroad, partly to the influence of the trade unions, whose interests had been progressively reconciled with those of the state by legislation for sickness insurance, for protection of agricultural workers and for collective bargaining. The defense of democracy thus brought together a united anti-Fascist and anti-Communist front. All parties backed the policy of sanctions against Italy at the time of the Italo-Ethiopian War; the clamour for disarmament was silenced when Germany began rearming; and the Dutch Nazi movement was discredited. Another symptom of the change was the entry of the Socialists into the cabinet for the first time, when D. J. de Geer formed his second coalition ministry in Aug. 1939.

Colonial policy meanwhile was marked by a certain readiness to meet the demands of the rising Indonesian nationalism. A *volksraad* ("people's council"), set up in 1918 in accordance with an enactment of 1916, included Indonesian members, some of them elected by local councils. Proposals for enlarging Indonesian membership and for giving greater independence to the governor general were passed by parliament (1925) only with a conservative amendment. This watering-down of the original bill evoked protests both from the Islamic and Socialist sections of the Indonesian nationalist movement and from the Socialists in the Netherlands, and a rebellion broke out in Java in Nov. 1926. Nationalist leaders such as Mohammed Hatta and Sukarno were arrested and interned for varying periods in the following years. A petition of the *volksraad* for a round-table conference at which the whole position of Indonesia could be discussed was rejected by the Dutch government in 1936.

World War II.—The German invasion of the Netherlands began on May 10, 1940. The centre of Rotterdam was completely destroyed by aerial bombardment on May 14, and the Dutch armies had to capitulate after five days of fighting. The royal family and the government went into exile in London. In the occupied Netherlands a German administration was set up, and Arthur Seyss-Inquart, as *Reichskommissar*, tried with increasing severity to bring the country into conformity with the Nazi pattern. Parliament and parties were dissolved, Dutch Nazis were nominated to various posts and the process of integrating the Dutch economy with the German started with the compulsory delivery of huge quantities of foodstuffs and culminated in the deportation of thousands of men to labour in German factories. The "Labour Front" absorbed the trade unions one by one, and a Chamber of Cultural Activities subjected literature and the arts to Nazi ideology. Of the Jewish population only about one-tenth survived.

The distribution of illegal newspapers started the resistance movement in June 1940. There followed strikes, such as those against the deportation of Jews (Amsterdam, Feb. 1941) and against the retention of Dutch soldiers as prisoners of war (May 1943) and the railway strike during and after the battle of Arnhem (1944). The resistance movement was supported by the overwhelming majority of the people, though hundreds were put to death or imprisoned. Contact with the London government was maintained throughout the war. The worst experiences of the population came in the winter of 1944–45, when the Allied and German forces were fighting over the country. The island of Walcheren was flooded when the Allies bombarded the dike at Westkapelle in the struggle for Antwerp, the Germans resorted to thoroughgoing terrorism and food and fuel were quite unobtainable to civilians except by scavenging or expensive barter. (*See* also appropriate subsections of WORLD WAR II.)

De Geer was relieved of the prime ministership in London after an abortive attempt to mediate between Great Britain and Germany (Sept. 1940). His successor, Pieter Gerbrandy, in close contact with Queen Wilhelmina, continued the struggle. When the Japanese attacked Indonesia, the Netherlands East Indian navy under Adm. Karel Doorman perished in the battle of the Java sea (1942) and Indonesia, too, fell under enemy occupation. Until the Netherlands and Indonesia were liberated by the Allies,

the government in exile exerted its authority through its control over the remainder of the navy and merchant marine and the Caribbean colonies.

The Postwar Situation and the Accession of Juliana.—On the defeat of Germany, Gerbrandy's government offered its resignation to the queen. An interim government under Willem Schermerhorn, formed in June 1945, included representatives of all parties except the Communists, who refused the one seat offered them. Economic and social life had to be rebuilt. The productive capacity of the country had been reduced by 60%, stocks were almost exhausted and only 63% of the houses remained undamaged. Deported workers and prisoners had to be brought back and employed; financial regulations were needed for commerce; salaries and prices were fixed. In the first postwar years the Netherlands was economically dependent on the U.S., and Marshall Plan aid (1947) made possible the rebuilding of Dutch industry. Meanwhile a special tribunal to deal with traitors, collaborators and war criminals was set up. Also, the Dutch claimed indemnity from Germany and annexed some areas in April 1949. (In April 1960 the villages of Elten, Dinxperlo and Tuddern were retroceded to Germany, while some minor concessions were made to the Netherlands in return.)

Queen Wilhelmina relinquished her powers on two occasions (Oct.–Dec. 1947 and May–Aug. 1948) to her daughter Juliana and abdicated in her favour on Sept. 4, 1948.

Internal Politics After World War II.—The churches and the political parties began gradually to renounce the idea that party and denomination must automatically coincide. A new political group, the Party of Labour (1946), included former Social Democrats, left-wing Liberals, progressive Roman Catholics and Calvinists and stressed its nondenominational character; but the majority of the Catholic party kept away from it. The dividing line between religious and nonreligious parties remained in being, but was much more fluid than it had been.

Four successive elections to the second chamber (1946, 1948, 1952, 1956) enabled the Catholics and the Socialists of the Party of Labour, together, to command an effective majority in parliament. Thus the first ministry of the Catholic Louis Beel and the four ministries of the Socialist Willem Drees consisted of coalitions in which these two parties shared most of the portfolios. A system of economic councils on which government, employers and employees were seated was set up, culminating in a Social Economic council as an advisory chamber; and the development of the welfare state was promoted by a further extension of old-age pensions and unemployment insurance, side by side with collective wage-fixing. This expansion of the state's control over economic life, however, provoked a revival of Liberal feeling and was the real reason why the Liberals, having participated in the cabinets of 1948 and 1951, left the coalition in 1952, though they made the Indonesian question their pretext for leaving. The growing demand for greater freedom in private enterprise moreover benefited the Liberal party in the elections, in which their strength rose from 6% of the votes in 1945 to 12% in 1959 (it fell however to 10% in 1963).

When Drees resigned in Dec. 1958 a caretaker government of Catholics and Calvinists, under Beel, took office till the elections of March 1959. Then, however, the Catholic party inclined to the Liberal view on the matter of wages, with the result that the postwar Labour-Catholic coalition broke up. In May 1959 a new coalition ministry under the Catholic Jan Eduard de Quay was formed, in which all the major parties except the Socialists took part (the Antirevolutionaries and the Christian Historicals had respectively 9.4% and 8.1% of the vote). In fact, the differences between government and opposition were largely a matter of degree rather than of principle, except for the Communists, who for a short time after the liberation strongly influenced a section of the trade unions and were able to organize widespread strikes.

At the elections of May 15, 1963, the Catholics slightly increased their strength, obtaining 50 seats out of a total of 150, while the Socialists declined from 48 seats to 43. The Liberals also fell, from 19 seats to 16. The newly formed Farmers' party won 3 seats. The Communist vote, which had declined between 1946 and 1959 from 10.5% to 2.4%, increased to 2.8% in 1963 (4 seats instead of 3 in 1959). A 69-day cabinet crisis was resolved on July 23 when Victor Marijnen, a Catholic, formed a new coalition government comprising the Catholics, the Liberals, the Antirevolutionaries and the Christian Historicals. The year 1964 saw the engagement and marriage (without parliamentary approval) of the queen's daughter, Princess Irene, to Prince Hugo Carlos of Bourbon-Parma, a Carlist pretender to the Spanish throne.

Marijnen's government resigned in Feb. 1965, and on April 12 another Catholic leader, Joseph Cals, formed a Catholic-Labour coalition. This government faced widespread objections to the engagement of the crown princess, Beatrix, to a West German diplomat, Claus von Amsberg; and the marriage, in Amsterdam on March 10, 1966, was the occasion of a major demonstration by the so-called "provos"—juvenile enthusiasts who agitated persistently on public affairs. Defeated in the second chamber on a budgetary question, Cals resigned on Oct. 15, 1966. Five weeks later Jelle Zijlstra, an Antirevolutionary, formed an interim cabinet. The elections of Feb. 15, 1967, were contested by 24 parties. Representation of both Catholics and Socialists in the second chamber was reduced, to 42 and 37 respectively. The Farmers got 7 seats, the Communists 5, the Christian Historicals 12, the Antirevolutionaries 15, and the Liberals 16. A new party, Democrats '66 comprising mainly young intellectuals and advocating abandonment of the system of proportional representation, won 7 seats. Four smaller parties shared the 9 other seats. On April 3 the Catholic Piet de Jong formed a new government: Catholics, Liberals, Christian Historicals, and Antirevolutionaries. A son, the first of the royal house since 1851, was born to the crown princess on April 27, 1967.

External Affairs.—The greatest problem in foreign policy was presented by the independence movement in Indonesia. The Japanese surrender (1945) left a power vacuum in the Netherlands East Indies which was filled only slowly by the arrival of British and Dutch forces. Meanwhile Sukarno, Mohammed Hatta and other Indonesian nationalists proclaimed a republic, which soon established its authority over Java and Sumatra. The Dutch government at first refused any contact with the republicans and, even after discussions with more moderate leaders (April 1946), continued to dispatch large forces to Indonesia. Hoping to create a United States of Indonesia that would be a partner in a Netherlands-Indonesian union, the Dutch sought to bring the states into being beside Sukarno's republic; and H. J. van Mook, as lieutenant governor-general, proceeded to recognize 15 such states, as approved by a special commission under Schermerhorn. Yet neither the right in the Netherlands, led by Gerbrandy, nor the republican extremists in Indonesia were satisfied by the "Renville" agreement of Jan. 1948, and a second military action was launched in December. Though this was stopped at the behest of the U.N. Security council, guerrilla fighting went on. Finally the round-table conference that had been demanded in 1936 met at The Hague; and under the agreement of Nov. 1949 sovereignty was conceded to Indonesia. Yet no solution could be found for the symbolic function of the monarchy at the head of a loose union of the Netherlands with a federal Indonesia. In fact Sukarno's republic, having absorbed the partner states, declared the union with the Netherlands null and void (1954). All Dutch economic and educational activities in Indonesia were gradually brought to an end; some Dutchmen were brought to trial for subversive activities; and at last the Dutch were virtually expelled. The Indonesian claim to Netherlands New Guinea (West Irian), as part of the East Indian inheritance, led to the breaking off of diplomatic relations in Aug. 1960 and, in Oct. 1962, to a Dutch-Indonesian agreement for the temporary administration of that territory by the United Nations. (*See* INDONESIA, REPUBLIC OF; NEW GUINEA.)

Meanwhile Queen Juliana in Dec. 1954 had signed the new Statute of the Realm, whereby the colonial status of Surinam and the Netherlands Antilles was abolished. These territories and the Netherlands proper were recognized by the statute as fully autonomous parts of a single kingdom.

Apart from the Indonesian question, the foreign policy of the Netherlands after World War II clearly showed that the idea of

association had replaced that of neutrality. A member of the United Nations from 1945, the Netherlands in 1950 sent a contingent to the U.N. forces in the Korean War. The Netherlands also joined the North Atlantic Treaty organization, the Council of Europe, the European Defense Community and the Western European union. In the sphere of international economic co-operation, plans for the Benelux union (Belgium, the Netherlands and Luxembourg) had already been put forward during the war (1944), but the divergent interests of agriculture proved an obstacle to full integration. Similarly the Netherlands, having been a member of the European Coal and Steel Community from 1952, joined the European Economic Community from its inception; but here again agricultural interests caused problems even before France's revolt, in the mid-1960s, against the ideal of "supranationality" to which the Netherlands, with other members, still adhered. (F. DE J.; X.)

V. POPULATION

The population of the Netherlands (1960 census) was 11,461,964. The average density was 821 per square mile. This density, one of the highest in the world, was chiefly the result of an intense concentration within the two provinces of North and South Holland (1,832 and 2,194 per square mile).

Between the years 1830 (the date of the separation of Belgium from the Netherlands) and 1962 the population of the Netherlands rose by 9,000,000. The greater part of this increase took place during the 20th century, mainly through the birth rate exceeding the death rate. In the years after World War II there was a large increase in the birth rate, and between 1945 and 1956 it averaged approximately 1% of the population yearly. A high proportion (37.4% in 1954, 38% in 1963) of the population is within the age group under 20. When Indonesia became independent about 200,000 Dutch nationals were repatriated to the Netherlands.

As a result of this population increase and of accompanying postwar economic difficulties, emigration, which was only moderate before 1939, increased for a time after the war (62,737 in 1956). But above all the Netherlands was compelled to intensify industrialization. The start of industrialization in the Netherlands was rather late, but during the 20th century there was an increasing drift into urban areas and in 1962 the 98 towns of more than 20,000 inhabitants contained about 60% of the population. Of the working population—in 1960 numbering more than 4,000,000 (about 3,241,000 male and 920,000 female)—41% worked in industry, 11% in agriculture and fisheries and 48% in other services.

The highest concentrations of population are found in South Holland, southern North Holland and the greater part of Utrecht, an area which is less than one-fifth of the country, but which contains about 43% of the total population. Most of the largest towns are to be found there, six of which have more than 100,000 inhabitants. The area is of a complex structure, comprising the strongly industrialized port districts of Rotterdam and Amsterdam. The towns of Utrecht, Haarlem, Leiden, Hilversum, Delft, Dordrecht and Amersfoort, the most eastern outpost of this area, are also much industrialized, as is the commune of Velsen at the mouth of the North Sea canal. The Hague, as the seat of government, is an administrative as well as a residential and industrial centre. The environs of Haarlem (Kennemerland) and the Gooiland, and the sandy area of the glacial region of Utrecht comprise a densely populated residential region.

Outside this main area, industry is spreading all over the region of the glacial ridges in the central part of the country. Although this region is predominantly one of mixed farming in addition to some traditional centres of industry (*e.g.*, Deventer, Apeldoorn, Arnhem, etc.), new small centres of industry (often in old towns) have developed. The most industrialized and thus densely populated is the district of Twente, the centre of Dutch cotton milling, with Enschede (1966 est. 135,407), Almelo (56,877) and Hengelo (67,053) as the largest towns.

In the province of North Brabant and the adjacent sandy parts of north Limburg and Gelderland, the abundance of superfluous labour on many of the small holdings has fostered the growth of light industries. The chief industrial town in this region is Eindhoven, which has risen from a modest market centre of 6,448 (1912) to a town of 181,609 (1966 est.). Tilburg (146,770), Breda (117,427), Nijmegen (142,022), 's Hertogenbosch (77,957, the largest cattle market in the Netherlands) and Helmond (46,142) have taken part in this industrialization. Another area with a relatively high density of population is southern Limburg, where the fertile loess plateaus and the coal mines support a density up to 1,100 persons per square mile. The agglomerations Heerlen-Kerkrade (127,659) and Sittard-Geleen (70,294) are the principal mining centres. A second densely populated area clusters around the industrial town of Maastricht (94,992).

The most sparsely populated regions are Zeeland and the adjoining clay region of North Brabant and the three northern provinces, all of which are largely farming country. More industrialized is the former peat-bog region of Veenkolonien, where a varied industry is gaining over the formerly exclusively agricultural industries. The only large town in this region, Groningen (pop. [1966 est.] 154,092), has market and service functions. (H. J. KE.)

Area and Population of the Netherlands

Provinces	Area (1966; sq.mi.)	Population (1966 est.)	Density (1966; per sq.mi.)	Census (1960)	Capital	Population (1960)

VI. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution and Government.—The kingdom of the Netherlands is a decentralized unitary state with a hereditary monarchy vested in the house of Orange-Nassau. The constitution regulates the powers of the monarch, parliament and franchise, administration of justice, provincial and municipal administration, defense, public finance, education, etc. It also safeguards freedom of religion and speech, of association and assembly and of the press. First promulgated in 1814, it has been frequently revised.

In default of a male heir, succession to the throne passes to the female. Executive power resides in the sovereign (*i.e.*, the monarch and the ministers, together called "the crown"). It comprises command of the armed forces; conduct of foreign relations, with the proviso that the assent of the states-general (statengeneraal, or parliament) is necessary for making war or peace and, in most cases, for the ratification of treaties; the appointment and dismissal of ministers; and the right to dissolve the two chambers of parliament separately or jointly. In this capacity the crown is assisted by the council of state (*raad van state*) of 20 members, which advises it on bills before their submission to parliament and on royal decrees of a legislative character. The council also advises the crown on administrative litigation requiring crown decision. The council of ministers (*ministerraad*), which is the *de facto* executive, consists of the minister-president (prime minister), appointed by the sovereign, and the ministers, including those without portfolio, and the undersecretaries of state (introduced in 1948). The ministers plenipotentiary designated by the governments of Surinam and the Netherlands Antilles (*see* below) have an advisory vote. In the event of a dispute between government and parliament, the sovereign, on the responsibility of the cabinet, may make use of his constitutional right to dissolve parliament, but only once.

Legislative power is exercised jointly by the sovereign and by the states-general. It consists of a lower house (*tweede kamer*, or second chamber) of 150 members elected for four years by direct, compulsory universal suffrage (of persons 23 years of age and older) through a system of proportional representation; and of an upper house (*eerste kamer*, or first chamber) of 75 members sitting for six years; every three years half of the latter resign. Members of the first chamber are elected by the provincial estates. Members of both chambers must have attained the age of 30. Voting is compulsory for all elections of the states-general and of the provincial estates and municipal councils.

Bills are sent by the sovereign to the second chamber after consultation with the council of state. Public discussion is preceded by inquiries by committees or departments. The second chamber may pass or defeat bills and has also the right of amendment. The first chamber, although it may discuss bills passed by the second, can thereafter only accept or reject them. In the latter case, it returns them to the sovereign to be reconsidered. Bills passed by both chambers become acts through the signature of the sovereign. The right of the second chamber to initiate legislation is seldom used. Control of the state's finances is entrusted to the auditing court (*Algemene Rekenkamer*), consisting of three life members.

Overseas Territories.—Under the constitution the kingdom of the Netherlands includes Surinam and the Netherlands Antilles (*q.v.*), which have complete domestic independence. Legislation concerning the whole kingdom (*e.g.*, on defense) is passed only after consultation with the overseas representatives. The former Indonesian possessions now constitute the independent Republic of Indonesia.

Local Government.—The Netherlands is divided into 11 provinces (*see* Table) with identical legal structures. Each province is governed by a representative assembly known as the provincial states (*provinciale staten*), composed of 35–82 members (depending on the number of inhabitants) and elected for four years with power to establish provincial regulations, which generally require approval of the crown. Its executive consists of six members with a royal commissioner, who together constitute the council of deputed states (*gedeputeerde staten*), which supervises municipal administration and the water boards. Both provincial and deputed states are presided over by the royal commissioner, who is responsible for the implementation of their decisions and for the maintenance of public order in his province.

The unit of local government is the municipality (*gemeente*). Its principal organ is the municipal council (*gemeenteraad*), consisting of 7–45 members (according to the number of inhabitants). It can institute bylaws with penalties for their infringement and may be called upon to execute the laws and decrees of the central and provincial governments. The municipal executive is composed of a burgomaster, appointed by the crown for six years, and two to six aldermen elected for four years by the council from its members. The burgomaster is responsible for public order and the council appoints a town clerk and a treasurer. Municipal co-operation is regulated by the Joint Organization act (1950) and assisted by the Union of Netherlands Municipalities, created in 1912.

The water boards (*waterschappen*) control water, dikes and certain roads, through ordinances which require the approval of the deputed states of the provinces. Usually there is a board elected by local landowners from among themselves; and an executive committee consisting of a dike reeve (*dijkgraaf*) and other reeves (*hoogheemraden*) charged with daily administration. The water board is one of the oldest forms of legal corporation in the Netherlands.

Purely functional decentralization is met with in the statutory organization of industry and trade, based on the Industrial Organization act, 1950, which provides a legal basis on which industry and trade can regulate their own affairs. A central statutory body, the social and economic council (*Sociaal-Economische Raad*), consists of 45 members appointed by the crown and by the organizations of employers and employees. It is both an advisory body to the government and the highest executive body of public industrial organization. There are also industrial boards (*bedrijfsschappen*) and commodity boards (*produktschappen*), which are set up by organized industry.

2. Political Parties.—The principal parties are: the Catholic People's party (*Katholieke Volkspartij*), which takes as its basis the principles of natural moral law and divine revelation; the Anti-revolutionary party (*Anti-Revolutionaire Partij*), which is Calvinist and accepts the Bible as the source of truth with regard to political as well as religious aims and is opposed to the principles of the French revolution; the Christian Historical union (*Christelijk-Historische Unie*), which is Protestant and considers the government to be the servant of God in the history of nations; the Political Reformed party (*Staatkundig Gereformeerde Partij*), also Protestant, which stands for government entirely based on God's law revealed in Scripture; the People's Party for Freedom and Democracy (*Volkspartij voor Vrijheid en Democratie*), which is liberal and lays stress on the individual liberty and responsibility of man; the Labour party (*Partij van de Arbeid*), a democratic-socialist party with a moderate socialist program; the Netherlands Communist party (*Communistische Partij van Nederland*), with a dogmatic Marxist program; and, finally, the Pacifist Socialist party (*Pacifistisch Socialistische Partij*), founded in 1957, with general disarmament as its principal aim.

3. Trade Unions.—The trade union movement in the Netherlands derives from mid-19th-century workmen's associations. Federation began in 1893, with the nonsectarian unions. Next, partly in reaction against them, came the socialist federation in 1905 (membership at mid-20th century, over 510,000). Catholic unions, organized on a local and diocesan basis and not according to trades, were federated in groups in 1924 and, after a period of internal disagreement, were united in the Catholic Workers' movement (*Nederlandse Katholieke Arbeidersbeweging*, 410,000). The Christian National Federation of Trade Unions (*Christelijk Nationaal Vakverbond*, 220,000) was formed largely in reaction against the syndicalist tendencies of the late 19th century. There are also nonaffiliated unions, with a membership of about 250,000. Membership in a union is not a condition of employment.

The unions have greatly contributed to the creation of a body of social legislation and to the general improvement of social conditions. Apart from the sphere of terms of employment, the federations are represented in numerous social and economic organs which act as advisory bodies to the government; they are also co-partners in the sphere of public law.

4. Taxation.—Taxation in the Netherlands consists chiefly of direct and indirect taxes, excise and customs duties. The most important direct taxes are the following: (1) corporation income tax on net profits; (2) dividend tax on share and bond dividends; (3) directors' tax on income derived from directorship of a company; (4) real estate tax on the sales value of property; (5) personal property and rental value tax, levied on the rental value of dwelling houses and the value of the furniture therein; (6) individual income tax, on income both of residents and of nonresidents with resources in the Netherlands. The principal indirect tax is that on sales or turnover, levied upon delivery of goods by a manufacturer or trader to another manufacturer or trader or to a consumer. Also subject to this tax are the importation of goods and the rendering of services for payment. Estate, transfer and donation duties, regulated by the Succession act, are collected from heirs or recipients.

The Benelux countries apply a common tariff of import duties to merchandise on importation into the various territories, in accordance with their customs agreement, the rates being moderate. As members of the Common Market, these countries keep their tariff policy in harmony with the obligations of the treaty of Rome.

5. Living Conditions: *Wages and Wage Policy.*—Before World War II, employers and employees were free to fix wages and other conditions of employment by joint consultation. Government intervention was restricted to a few exceptional cases. However, in 1945 the Extraordinary Employment Relations decree instituted a board of government conciliators (*college van rijksbemiddelaars*), which became the chief executive organ of wage policy. After 1955 the tendency was toward a freer wage policy, giving organized industry and trade unions a greater part in wage

determination. However, the ultimate decisive power remained with the central government.

Social Insurance.—In the 20th century extensive legislation accumulated in this field, comprising the Industrial Accidents Insurance act, 1921; the Agricultural Accidents Insurance act, 1922; the Seamen's Accidents act, 1919; the Disability act, 1913; the Unemployment act, 1949; the Children's Allowance act, 1939 (revised 1962); the Sickness Insurance act, 1930; and the Sick-Fund decree, 1941. Some acts set a wage limit which is periodically revised in the light of the national price index figures. Administration of the system is partly in the hands of the social insurance bank and the regional labour boards and partly entrusted to the 26 occupational associations established by the employers' and employees' unions. General supervision rests with the social insurance council.

Pensions.—The General Old Age Insurance act, which came into operation on Jan. 1, 1957, provides for compulsory old age insurance through contributions by all persons between 15 and 65 years of age. Pensions may be claimed at the age of 65 and fluctuate with the wage index figures. The act is administered by the social insurance bank, contributions being collected by the income tax authorities. The General Widows' and Orphans' act (1959) allows a pension varying with the age of the widow and the number of her children.

There are also a considerable number of private industrial pension schemes. Under the Industrial Pension Funds act (1949) the minister of social affairs may declare that participation in the branch fund is compulsory for a whole branch of industry, provided that he is so requested by a representative body of that branch. The Pension Funds and Savings Funds act (1954) contains regulations with which an employer has to comply once he has set up a fund for his company. Separate regulations, laid down in the Superannuation act (1922), apply to old age and disability pensions for civil servants. Contributions are made by both the civil servants and the authorities, and the amount of pension is correlated with the length of service and the latest salary.

Protection of Workers.—Adult male workers are limited by law to a 48-hour week and an 8½-hour day; but by the early 1960s a 45-hour week was being worked throughout industry, trade and the civil service. Special regulations apply to dangerous or unhealthy work and to overtime. There is legislation for the safety of workers, the prevention of industrial accidents and for special groups. Supervision of the observance of labour protection legislation is entrusted to the labour inspectorate.

Housing.—The Housing act (1901), frequently amended, is the legal basis for improvement of housing conditions. It provides for municipal bylaws laying down detailed rules for house construction, for the best use of land and for municipal financial support to local housing societies. Drastic government intervention was necessitated by the destruction and damage of World War II. This control was gradually relaxed; and by the 1960s municipalities and housing societies were the chief initiators of building. The total number of dwellings increased from 2,109,000 in 1945 to nearly 3,000,000 in the early 1960s.

6. Welfare Services.—Social work in the Netherlands is of long standing, though before the 20th century it was mainly confined to religious and private charity, concentrating on such groups as neglected children, old persons and delinquents. With the growth of the social insurance system there developed various kinds of aid of a more individual trend, in which stress was rather on personal guidance than on the material element. After World War II the development of social work was impressive.

Institutions can be classified as denominational (Protestant, Roman Catholic and humanist) or organizational. The latter group include the Central Council for Homemakers' Services, the National Federation for Child Welfare, the Netherlands Federation for Care of the Aged and the Netherlands Family council. Local collaboration between voluntary organizations and public authorities is effected by social councils. The ministry of social affairs (set up in 1952) has mainly co-ordinating, stimulating and subsidizing functions; it regulates subsidies to the various services or to village and district centres, etc. The organizations usually receive provincial and municipal as well as state subsidies.

State legislation concerning poor relief is represented by the Poor act (1912). In accordance with tradition this act starts from the principle that aid given by churches and private bodies comes first and that public assistance is only subsidiary. With the rise of social insurance the importance of the act is for those groups which do not come under the provisions of social legislation.

7. Health.—Health services are the care both of the government (including provincial and municipal authorities) and of private organizations. Supervision of public health is the responsibility of a directorate operating through five divisions: medical, pharmaceutical, veterinary, licensing and mental health. There are also specialized state institutions such as the institute for public health and the institute for drinking water supplies. Municipal activities comprise medical supervision of schools and disease control. The most important private organizations are the "Cross" associations, which originally had the improvement of home nursing as their principal purpose. They are Protestant, Roman Catholic or nonsectarian and have nearly 2,000,000 members. Their activities consist chiefly of preventive health care (operation of health centres, baby clinics and advice bureaus) and of home nursing through district nurses. Other private organizations specialize in tuberculosis, cancer, rheumatism, etc. Hospitals, sanatoriums and institutions for mental diseases are mainly run by private organizations; about 25% of hospitals are municipal. The population of the Netherlands is among the healthiest in the world and the average life expectancy of a Dutch child born at mid-20th century was more than 70 years.

8. Justice.—The judiciary occupies a position of independence because judges are appointed for life; furthermore under the constitution all civil disputes must be adjudicated upon by judges unless the parties agree to settlement by arbitration. In general, professional judges try both civil and criminal cases; trial by jury is unknown in the Netherlands. Laymen may preside only in a few civil cases and in cases concerned with administrative justice.

The ordinary courts comprise 62 magistrates' courts, 19 district courts, 5 courts of appeal and the supreme court at The Hague. The magistrates' courts (*kantongerechten*) are competent to deal with all ordinary civil cases involving amounts up to 500 guldens, besides disputes relating to leases, rents and labour contracts. These courts can also try minor criminal cases.

The district courts (*arrondissementsrechtbanken*) are competent in the first instance in all civil cases not left to the magistrates' courts and in all serious criminal cases. These courts also adjudicate on appeals against magistrates' courts' decisions. They consist of a number of chambers, some with three members, some with one, constituted by specialist judges for: (1) petty offenses (*politierechter*); (2) cases involving juveniles (*kinderrechter*); and (3) economic cases of a criminal nature (*economische politierechter*). The president of the court has the power to give immediate decisions in civil cases in summary procedure.

The courts of appeal (*gerechtshoven*) decide in the first instance on tax matters only. Their principal task is to consider appeals against the judgments of the district courts. They are divided into chambers consisting of three judges.

The supreme court (*De Hoge Raad der Nederlanden*) has three chambers, for civil, criminal and tax cases, and also tries ministers, high civil servants, members of parliament, etc. Its chief function, however, is to interpret rules of law in the last instance and to guarantee the uniform application of the law throughout the kingdom. To this end it has the power to reverse decisions of lower courts which it judges to be at variance with the law (*cassatie*), but it may only consider appeals in cases where appeal to a lower court is no longer possible. Its judgment is confined to points of law. Although its decisions have not the force of binding precedent, they are generally taken into consideration by lower courts in similar cases.

Legal assistance for parties to civil cases is compulsory except in magistrates' courts. In lower courts the legal representative is called *procureur;* in general, legal counsel is given by *advocaten.* In both civil and criminal cases free legal aid is given to persons without means.

The Public Prosecutor's Office.—Only in criminal cases can the public prosecutor's office institute proceedings; it is not obliged to prosecute every case of which it takes cognizance. However, a wronged party may petition a court of appeal to order the office to prosecute; such an order may also be given by the minister of justice. The public prosecutor's office consists of the attorney general and the solicitors general, who are attached, respectively, to the supreme court; and the public prosecutors and deputy prosecutors attached to the courts of appeal and to the lower courts.

Administrative Justice.—Courts concerned with the dispensation of administrative justice exist in certain special fields. There are courts dealing with social insurance laws and with regulations for civil servants. Appeals against the judgments of these courts are dealt with by the central council of appeal; a different council of appeal deals exclusively with appeals against decisions of statutory trade-organization bodies.

Police.—The Police act (1956) distinguishes between state police (*Rijkspolitie*) and municipal police. The state police corps comes under the minister of justice and is commanded by an inspector general. The corps is divided into districts and these into groups (the latter often subdivided into posts); it serves all municipalities with less than 10,000 inhabitants besides those with between 10,000 and 25,000 inhabitants which are listed in the act. The remaining municipalities of this latter group and all those with more than 25,000 inhabitants have police forces of their own, controlled by the burgomaster. The military corps of royal constabulary (*Koninklijke Marechaussee*) is charged with certain civil police tasks, such as guarding the frontiers: it is also especially charged with guarding the royal family. Other duties include the keeping of law and order and the investigation of offenses in the armed forces.

9. Education: *Primary Education.*—The constitution lays down that the cost of voluntary general primary education (fulfilling certain conditions imposed by law) is to be defrayed from public funds on the same scale as public education. State primary schools are run by the municipalities; voluntary schools by the organizations which set them up. The costs of both state and voluntary primary education are mainly borne by the municipalities; teachers' salaries are reimbursed by the state. State supervision is exercised by the schools' inspectorate. Primary education (compulsory since 1900) is free throughout the period of obligatory schooling (7–15 years of age).

In the early 1960s more than 1,500,000 pupils in nearly 8,000 schools (27% municipal) were receiving ordinary education. There were also 500 special schools for children with physical or mental handicaps. Infant education, which is not compulsory, is given in about 4,000 schools (75% voluntary) to more than 400,000 children in the age group 4–7 years.

Preparatory Higher and Secondary Education.—In this field, state and voluntary schools are not on the same financial footing. The oldest type of school is the gymnasium, developed from the former Latin school. It provides a six-year course; pupils may choose either the A stream, which stresses Latin and Greek, or the B stream, concentrating on the exact sciences. The Hogere Burgerschool (H.B.S.) gives a broad, general five-year course; it too has an A stream (literary and economic) and a B stream (stressing the exact sciences). The lyceum is a combination of the other two in the sense that after an initial course of one or two years its pupils choose either the gymnasium stream or the H.B.S. stream. There were about 450 of these types of schools in the early 1960s, with more than 170,000 pupils, about one-third of whom were girls.

The foregoing types of school prepare pupils for universities. Other types, which do not, are the commercial day schools, which give a three- or four-year course stressing modern languages, mathematics and commercial sciences; and the girls' secondary schools, which provide a five-year course. Commercial training is also given in commercial evening schools.

Technical and Vocational Education.—In this field there are about 1,370 schools and courses (technical, advanced technical, domestic, etc.), with about 450,000 pupils. In addition, there are more than 450 agricultural and horticultural primary and secondary schools, while more than 50,000 young people learn crafts or trades through apprenticeships.

University Education.—The Netherlands has six universities: Leiden (founded 1575), Groningen (1614) and Utrecht (1636), all state universities; Amsterdam (municipal, 1632); the Free (Vrije) University of Amsterdam (Orthodox Protestant, 1880); Nijmegen (Roman Catholic, 1923). There are two state institutes of technology (Delft and Eindhoven); and two schools of economics, Rotterdamse Economische Hoogeschool (private, nonsectarian) and Tilburg (private, Roman Catholic). The agricultural University (Landbouwhogeschool) of Wageningen is run by the state. The total number of university students is more than 35,000, of whom about one-sixth are women.

As a rule, universities have faculties of theology, law, medicine, mathematics, natural sciences, literature and philosophy. The universities of Amsterdam and Groningen also have faculties of economics and of political and social sciences. A degree in dentistry can be obtained at Groningen and Utrecht; the latter university has also a faculty of veterinary science. The expenditure of the state institutions is fully borne by the state; voluntary institutions receive state support varying from 70% to 90% of their costs. Student life is highly organized, both on the local and the national level.

10. Defense.—During the 19th century the armed forces were made up of various components, viz., a standing army of volunteers, a militia (mainly volunteers) and the local civic guards. A system of universal military training came into force in the 20th century. As provided in the Compulsory Service act (1920), all able-bodied men, on reaching the age of 20, are enlisted for military service. Army training is of 18 months' duration, cadre and specialized categories serving an additional period. Primary training may be followed up by periodical refresher courses. Regular officers are trained at the Royal Military academy at Breda; there is also a school for regular noncommissioned officers.

The naval forces of the Netherlands, drastically reduced during World War II, consist of a fleet of postwar-designed cruisers, destroyers, submarines, aircraft patrol boats and an aircraft carrier. The navy incorporates the naval air service and the royal marine corps. The naval officers' training institute is at Den Helder, the main naval base in the Netherlands. The royal air force, which had also lost most of its craft during World War II, was gradually re-equipped with modern squadrons of jet fighters, fighter-bombers and other types. It has 13 operational air bases. The three women's voluntary auxiliary corps (attached to the army, navy and air force) function mainly in the field of liaison and medical care. The Netherlands' post-World War II forces were built up according to the country's NATO obligations; and they are also responsible for the defense of the oversea possessions.

Civil Defense.—Under the responsibility of the royal commissioners and the burgomasters, civil defense corps are set up and trained for emergencies. In addition, undertakings of a certain size are obliged to provide for self-protection. A number of mobilized military units were created to assist in the defense of the interior and to support the civil defense corps. (P. W. v. W.)

VII. THE ECONOMY

Although agricultural products form an important part of the national exports, the Netherlands is a highly industrialized country. Next to the export of industrial products, the export of services (shipping, investment, brokerage, etc.) contributes to the balance of payments.

A. Production

The agricultural prosperity of the Netherlands probably owes more to the ingenuity and labours of its engineers and farmers than to the natural fertility of the soil, which is rather poor. The total of farm and horticultural land is about 5,700,000 ac., approximately 70% of the country's area; of this, nearly two-fifths is plowland, about three-fifths grassland and 340,000 ac. horticultural area. Woodland covered 690,000 ac. in 1961 and infertile regions, 525,000 ac.

Arable Farming.—The main agricultural area comprises parts of the reclaimed polder lands of the coast from Zeeland to Groningen. Those of the southwest (Zeeland, northwestern North Brabant and the islands of South Holland) and along the Frisian and Groningen coast are composed of heavy marine clays which, after preparation, yield good grain (especially wheat and barley) and root crops. A second agricultural area is formed by the former peat-bog regions of Groningen, Drenthe and northeastern Overijssel. The specialized farming of this region produces cereals, especially rye, oats for fodder and potatoes. A third and new agricultural region consists of the reclaimed Zuider Zee polders with wheat as their main crop.

In the polder lands of North and South Holland and in western Utrecht, arable farming is mainly restricted to the surface of drained lakes. The rest is rich pasture which supports a dairy and cattle industry. In the south, because of the proximity of large communal centres, there is an emphasis on market gardening. The polders of Friesland are cattle-raising areas and rival those of North and South Holland. The clays of the central river deltas do not offer such good farming land as the marine clays. Large districts are therefore given over to grazing land, though where conditions have been improved there is mixed farming and horticulture. A part of this region (especially the Betuwe) is also one of the principal orchard districts. The sands and gravels of southern and eastern Netherlands have a somewhat poor soil. Cultivation, through clearing and reclaiming of local peat areas and marshes, drainage and irrigation, has been much extended during the 20th century. The sand regions have become the most important region of cattle farming, and at 's Hertogenbosch and Zwolle the largest cattle markets of the country are held. Farming is of a mixed type; the arable land is planted with rye, oats and potatoes, which are all used for fodder. Next to horned cattle, pigs and poultry make up the livestock.

Southern Limburg forms a district apart. Instead of sand, it possesses a high proportion of fertile loams which are roughly half arable and half pasture. The development of the region as an industrial area stimulated dairy farming and market gardening.

On the whole the farms of the Netherlands are of small and medium size. In the clay regions, where farming is mostly arable, the holdings have an average size of 100 ac.; holdings larger than 250 ac. are frequent. In the sandy regions many small farms still occur, but through reallocation and the buying up of small holdings more and more farms are attaining the size that is normal for this type, about 40 ac. Holdings of the former peat-bog region have an average size of about 70 ac.

The area under wheat has increased, partly as a consequence of the reclaiming of the Zuider Zee polders. Similarly, the area under oats is increasing with more intensive cultivation. Of the other crops, potatoes are grown for human consumption, for seed and for commercial preparations such as potato flour, glucose and dextrine. Sugar beets and fodder beets are grown particularly in the north and the southwest. Traditional crops like madder and rapeseed, chicory, hemp and even flax have either vanished or are in decline, being supplanted by caraway, poppy and colza and especially by seed potatoes. Agricultural processing also includes the making of strawboard and cellulose. Both these industries, whose products are much exported, are concentrated in the northeast, especially in the former peat-bog region (Veenkolonien).

Horticulture.—Horticulture, long an important aspect of Dutch agricultural life, became in the 20th century a principal item in the export trade. The area under market gardening in the 1960s was about 340,000 ac. It flourishes particularly in the provinces of North and South Holland. A strong regional specialization occurs. In the region between Rotterdam and The Hague (Westland) and to the north of Rotterdam the growing of vegetables under glass predominates. The inner side of the dunes between Leiden and Haarlem is almost entirely devoted to bulb growing (principally tulips, hyacinths, daffodils, gladioli, crocuses and narcissuses). The region north of Alkmaar specializes in cabbage, that between Hoorn and Enkhuizen in fruit and flower seeds. There are also some local centres for flower growing (Aalsmeer) and for pot plants and shrubs (Boskoop). Main centres of horticulture elsewhere are in Zeeland, western North Brabant and Limburg.

Cultivation of fruit has developed considerably throughout the whole country. Pasture or arable orchards predominate in southern Limburg and on the river-clay districts of Gelderland and western Utrecht. Orchards of apples, pears and plums, among which grow various bush fruits, are found particularly in Zeeland (South Beveland), in the west of North Brabant and in South Holland.

Animal Husbandry.—Animal husbandry is mainly concerned with the production of milk and its derivative products. There is also considerable breeding and export of dairy cattle (famed Holstein-Frisian cows). The supply of meat for the home market is obtained by fattening part of the dairy herd, which in the early 1960s exceeded 3,800,000 head. Special breeds of beef cattle do not occur in the Netherlands. The oldest centre of the dairying industry is the pasture polders of North and South Holland and of western Utrecht. More important, however, for the production of butter, cheese and other milk products are the dairy farms of Friesland and the sandy regions. This production is almost entirely centred on about 500 dairy factories, of which almost 70% are co-operative.

Pigs (between 2,500,000 and 3,000,000) are of two kinds: the Dutch pork pig, bred chiefly for the home market, and the bacon and ham pig for export. They form part of the mixed-farming economy of Overijssel, Gelderland and North Brabant. Poultry raising and egg production are important in the same areas.

Forestry.—Although the government has planted large forests in the sandy regions, especially in Drenthe, forestry plays only a small part in the economy of the Netherlands.

Fisheries.—From the middle ages, herring fishing was a principal occupation of the Dutch. During the 20th century, chiefly because the country failed to keep its fleet modernized, deep-sea fishery tended to decline; the rich fishing grounds of the North sea were favoured in preference to more distant grounds. Herring constitutes the chief catch, with plaice, sole, cod and mackerel of less importance. Chief fishing ports are IJmuiden, mainly for fresh fish, and Scheveningen and Vlaardingen for herring. Coastal fisheries concentrate on mussels, oysters and shrimps.

Industry.—The industrialization of the Netherlands, though retarded by a lack of natural resources and by a paucity of coal, grew steadily after the mid-19th century. An increasing population and limited land made it essential to exploit economic resources other than commerce. Local agriculture and tropical products were developed and the traditional industries such as shipbuilding, textiles and paper production were modernized. As a commercial country, the Netherlands had an abundance of private capital. Initially the emphasis was upon the technical improvement of existing industries in the ports. The agricultural resources of the Netherlands were adapted to milk processing, margarine manufacture, potato-flour milling and strawboard production. Later, capital and scientific research were applied to technical industries which required a minimum of raw material, such as electrical and radio equipment, synthetic fibres, and component parts. At the beginning of the 20th century the introduction of heavier basic industries began with the exploitation of the Limburg coal field and, later, of the salt beds in eastern Overijssel, near Hengelo, and Groningen (Delfzijl). As a result coking, chemical and, later, iron and steel industries have developed.

Damage and loss in World War II was aggravated by the loss of Indonesia, by shortages of both dollars and sterling and by a lack of skilled labour. Further industrialization of the country (necessary in view of the great increase of population) became more and more dependent upon a close integration of Dutch industry with that of western Europe and a comprehensive liberalization of trade, together with financial support from such plans as the European Recovery program till 1954. The percentage of population engaged in industry rose steadily from about 34% of the working population in 1899 to more than 40% in the early 1960s (see *Population*, above). Industrial production rose considerably after World War II, especially from 1954, while labour productivity rose satisfactorily. After 1955 it was even necessary to import workers

from other European countries to meet a labour shortage.

The chief industrial regions are North and South Holland and Utrecht. Outside Holland and Utrecht there are industrialized regions in North Brabant, parts of Gelderland, Overijssel, Groningen and southern Limburg. Industry is largely based on medium-sized or small private undertakings. After 1960 there were about 10,500 undertakings (of 10 or more workers) with a labour force exceeding 1,000,000. Governmental policy has been to stimulate further industrialization, especially in those parts where economic development is lagging, as in the northern provinces.

Mining, Fuel and Power.—Coal, in the south of Limburg, is worked by state and private enterprise, the latter by a concession from the state. Technically the industry is well advanced.

The refining of petroleum was not important in the Netherlands before World War II. Of the total oil import in 1938, about 26% was crude oil. In postwar years domestic production was increased, chiefly from the Schoonebeek oil field in Drenthe, and later from the western part of the Netherlands, around Rijswijk. In the early 1960s about 20,000,000 tons were imported annually and refined at Pernis, along the New waterway. By 1960 the Netherlands was already the most important exporter, after Great Britain, of petroleum products in Europe.

Natural gas was discovered in the Netherlands in 1948. It remained economically unimportant till the Slochteren field, in the province of Groningen, was discovered in 1960. Proven reserves are 1,100,000,000,000 cubic metres, which is about half the west European total. The state and the state-owned coal mining company, together with the two leading oil companies in the Dutch market, share the ownership of the gas distribution company, thus making a well-balanced energy policy possible. Inland distribution started in 1964; export to Germany and other countries was the subject of negotiation. To increase consumption an aluminum plant was projected in Delfzijl. Prospecting for oil and natural gas was taking place in the Frisian isles and adjacent seas.

Electricity is furnished by thermoelectric plants which are fired by coal or oil. The annual consumption is 15,500,000,000 kw.hr.

Metallurgy.—Despite its great lack of mineral deposits, during the 20th century the Netherlands has built up a metal industry. Between 1930 and 1950 the number of workers rose by 95%. Iron smelting was begun in 1924 at IJmuiden with ore chiefly from Spain and Sweden, and steel is produced there and in Utrecht. Nevertheless, steel is imported from Belgium, Germany and Great Britain (for shipbuilding). Tin and zinc are smelted.

Shipbuilding.—Shipbuilding and repairing has long been one of the Netherlands' chief industries. Numerous shipyards are found along the rivers between Schiedam and Dordrecht in the southwest, at Amsterdam and, to a lesser extent, Hoogezand-Sappemeer (Groningen), which specializes in smaller vessels (coasters). In the mid-1960s there were nearly 200 shipyards with more than 25 workers. Shipyards have tended to switch to the more profitable business of petrochemical plant construction.

Engineering.—The Dutch metal industry has been created chiefly as an ancillary to shipbuilding and maintenance of the merchant navy. At first the engineering industry specialized in marine engines, and in machinery for domestic and colonial industries and for public works, such as oil-well equipment, tin dredges, pumps and metal constructions such as bridges and house frames (the latter in particular at Gorinchem, Dordrecht). Lighter electrical and wireless equipment have since become important. Chief centres are at Eindhoven and Nijmegen. Since World War II the aircraft industry, including the manufacture of component parts and specialized technical equipment, has developed increasingly.

Chemicals.—The Dutch chemical industry developed in connection with the salt deposits at Boekelo (Overijssel) and at Delfzijl (Groningen). Nitrogenous and phosphate fertilizers, coal derivatives, refinery products, paints and pharmaceuticals, etc. are also manufactured or processed.

Textiles.—The manufacture of woolen cloth in most of the medieval towns, but in particular at Leiden, was formerly the Netherlands' most important industry, which benefited from the immigration of skilled workers from Flanders in the 16th century. Later the linen industry developed in the Twente district. In the 19th century this industry turned its attention to cotton, and gradually Twente and North Brabant became the chief textile areas, with the woolen and linen manufacture concentrated in North Brabant. Other textile manufactures were rayon, lace and carpets. Hosiery is made in many towns, and ready-made clothing especially at Amsterdam, Groningen and in the Twente district.

Other Industries.—Leather and footwear are produced in the towns of North Brabant and also at Nijmegen in Gelderland; production after World War II was roughly adequate to home demands. A timber trade, chiefly concentrated in the towns of North and South Holland, especially at Zaandam, produces wood for building and supplies the pulp and paper industries. The latter is supplemented by the production of strawboard from cereal straw. The rubber industry expanded after World War II, chiefly in the production of tires (The Hague, Enschede, 's Hertogenbosch) and other consumer articles. Food industries are principally concerned with sugar (manufacturing and refining), milk products and vegetable oils; cigars are made. The diamond-cutting industry of Amsterdam declined greatly after World War II.

Tourism.—Receipts from tourism are significant to the economy and by the early 1960s more than 4,000,000 tourists from abroad were visiting the Netherlands annually. The coast line of the North sea with its broad beaches of sand are popular vacation areas. Scheveningen, Zandvoort and Noordwijk are the chief seaside resorts. The Frisian islands have also become popular holiday places. The many lakes and broad waterways of Friesland are good for yachting, as are the broad estuaries of the southwest. The Netherlands has many old towns of which Amsterdam (with its canals), Delft, Leiden, Gouda, Alkmaar, Zierikzee, The Hague and Maastricht are of great interest. Outside the provinces of North and South Holland are many remarkable, and mostly smaller, old towns, and many rural regions (in particular the province of Drenthe and the eastern part of Gelderland) still offer an unspoiled landscape. The new polders in the Zuider Zee region, as interesting examples of new developments, attract many sightseers.

B. Trade and Finance

Foreign Trade.—The Netherlands shows the characteristics of a densely populated and industrialized country, which has by its increasing population been compelled to stimulate its exports. Nevertheless, imports exceed exports, though the cover of visible imports by exports is increasing (1938, 73%; 1962, 88%).

Imports are largely made up of agricultural raw materials, particularly linseed, peanuts for chemical production, maize (corn) for fodder and wheat for human consumption; mineral raw materials, mineral oil and chemical raw materials; hides, raw rubber and rubber produce; wood, chiefly timber for constructional purposes; textiles and clothing; base metals, chiefly iron and steel, and finished machinery and rolling stock. Exports comprise agricultural produce, chiefly dairy products, vegetables, flowers, bacon, stock guts and oils; chemicals, mainly coke and fertilizers; paper and wood products; textiles, chiefly cotton goods and rayon yarns; metal products, such as ships, dredgers, instruments, radio and electrical equipment and tin.

In the early 1960s Belgium and Luxembourg, the Federal Republic of Germany, the United States and Britain were the Netherlands' chief suppliers. Its exports go mainly to Germany, Belgium and Luxembourg, Britain and the United States.

The Royal Netherlands Industries fair (Koninklijke Nederlandse Jaarbuers) organizes the important spring and autumn fairs at Utrecht and other specialized trade events.

Currency and Finance.—The monetary unit, the gulden or guilder (*f* designating the ancient florin), dates from 1795; it is divided into 100 cents. The Netherlands was the last country to abandon the gold standard (Sept. 19, 1936). The gulden was devalued with the pound in Sept. 1949; its exchange rate in relation to the U.S. dollar fell from *f* 2.65 to 3.80 and in relation to the pound was fixed at *f* 10.64. In 1961 the gulden was revalued; its relation to the dollar was fixed at *f* 3.62 or *f* 10.90 to the pound. (*See* Monetary Unit.)

The Netherlands bank, founded in 1814, was for long a private

institution but was nationalized on Aug. 1, 1948. It acted as the government's banker, and the state, in return for its privilege of issuing notes, shared in the profits.

The Netherlands possesses about 40 joint-stock banks, of which the larger are intimately concerned with industrial financing; farmers' credit banks, serving agricultural co-operatives, form a substantial section of Dutch banking.

Budget.—The Netherlands budget is divided into ordinary and capital services, both on the revenue and expenditure side. Until 1931 budgets usually showed a surplus. As a result of the economic depression of the earlier 1930s this was transformed into a small deficit. With the devaluation of the gulden in 1936, however, revenue began to increase, and in the years after World War II a surplus was once more being recorded. Postwar budgets had to provide for increasing expenditure particularly for education, social services, defense, construction of houses, roads and dikes (Delta project) and agriculture.

The local provincial and communal authorities possess some degree of financial autonomy and derive small revenue from various types of taxation, mostly supplemented by grants from the state. A chief responsibility of these local bodies is the maintenance of local roads, etc., public health, education and the police.

The national debt steadily increased after the 19th century. The 1938 total of *f* 3,986,000,000 had increased about five-fold by the early 1960s and included £974,000,000 of foreign debt.

C. Transport and Communications

Railways.—The Dutch railway network (Nederlandsche Spoorwegen, a limited liability company with the state as sole shareholder) has been maintained at an economic length. The total length in the early 1960s was 2,021 mi., of which about 1,009 mi. were electrified. Passenger traffic is of greatest importance, and little bulk freight is handled by rail.

Roads.—The development of the road system was handicapped in many areas by the nature of the land surface which is broken by large rivers and estuaries. Just before World War II considerable progress was made toward a national network by the building of many bridges for road traffic. Roads comprise main state highways, secondary and third-class roads; motorways are growing in importance. The road system, relative to others in Europe, is well developed.

Inland Waterways.—The artificial waterways were constructed originally for land drainage rather than for the carriage of goods. Later, with the considerable stretches of navigable rivers, they were found very suitable for carrying both domestic and transit goods and their network was extended. Open rivers and the main shipping canals are mostly state controlled, except in the northeast, where they are partly administered by the provincial authorities. The total length of navigable waterways was 3,600 mi.; the length navigable by barges carrying more than 1,500 tons was 1,081 mi. (which includes 429 mi. in the IJsselmeer and Delta areas).

Of the main systems that of the Rhine and its offshoots is the most important and can carry barges with a capacity of 4,000 tons. Amsterdam is connected to the sea by the North Sea canal. Another large canal (for vessels of more than 2,000 tons) connects with the Waal at Tiel, and smaller canals lead to Rotterdam, which also has an artificial connection with the sea by the New waterway. A second system is that of the Meuse, the Juliana canal and the canals of North Brabant; this links central and western Netherlands with southern Limburg and the eastern Belgian system. In the eastern and northern provinces many smaller canals carry agricultural goods. The Twente canal, which connects the industrial Twente district with the Rhine system, and the new canal system in the northern provinces (from Delfzijl-Groningen to Harlingen and Lemmer) take ships up to 1,350 tons.

Before World War II the Dutch inland fleet was the largest of western Europe, with around 20,000 craft (4,454,000 ton capacity). In the early 1960s it possessed more than 19,000 vessels of about 5,325,000-ton capacity. The waterways are responsible for more than half of the internal traffic of the country. They also play an extremely important part in transit trade. Rhine-borne traffic figures alone were 28,200,000 tons downstream and 27,600,000 tons upstream in 1938, to be compared with 25,033,000 and 53,388,000 in 1961.

Sea-Going Shipping.—The Dutch have long been a seafaring people, though during the Napoleonic wars their flag practically disappeared from the seas. A revival of their maritime importance began in the latter part of the 19th century, when several shipping lines were established. In spite of severe damage during World War II, the mercantile fleet by Jan. 1963 comprised 1,525 ships of 5,037,000 gross registered tons. The earnings of the Dutch merchant navy were second only to revenue derived from investments abroad. A particular feature of the Dutch merchant fleet is the many small vessels (coasters), which are mostly engaged in carrier trade; many of these are based on Groningen.

The chief Dutch ports are the ports of the Rotterdam district (Rotterdam, Vlaardingen, Hook of Holland, Schiedam and Dordrecht) and Amsterdam. The Port district of Rotterdam comprises a large series of docks on the southern side of the New waterway at the mouth of which there are new docks of large capacity (Europoort). Amsterdam benefited from the cutting of the North Sea canal across the centre of North Holland and from its artificial connection with the Rhine. Of the remaining ports Delfzijl (on the Ems), Flushing (on the isle of Walcheren) and Harlingen (on the Wadden zee) are the most important.

In cargo traffic Rotterdam overshadows all other ports of the country, its chief rival being Antwerp rather than any Dutch port. It handles eight times as much as Amsterdam, its nearest Dutch competitor. Through Rotterdam also passes by far the greater part of transit traffic that makes up about 40% of the total imports and 30% of the total exports.

Airways.—The Royal Dutch airlines (Koninklijke Luchtvaart Maatschappij or K.L.M.), founded in 1919 with government aid as a private enterprise, provides regular air services throughout Europe and between Europe and America, to the near and far east and to Australia.

Telecommunications, Radio and Television.—The post office, telegraph and telephone systems are operated by the postal administration. Radio broadcasting is controlled by five noncommercial associate companies (owned by religious or political organizations) which under a charter of 1947 merged their facilities in the Nederlandsche Radio Unie (Netherlands Radio union). They each retain autonomy in planning and transmission during hours allotted by government decree. They also control the Nederlandse Televiesie Stichtung (Netherlands Television foundation). Overseas broadcasting is carried on by Radio Nederland Wereldomroep (Netherlands World Broadcasting), controlled by the ministry of education, arts and sciences.

Current history and statistics are summarized annually in *Britannica Book of the Year.*

NETHERLANDS ANTILLES (NEDERLANDSE ANTILLEN), two widely separated groups of Caribbean islands in the Lesser Antilles. The southern group, comprising Curaçao (*q.v.*), Aruba and Bonaire, lies less than 60 mi. off the Venezuelan coast. The northern group includes St. Eustatius (*q.v.*), Saba and the southern part of St. Martin (Sint Maarten); geographically this group lies within the Leeward Islands.

Area, Population and Principal Towns

Island	Area (sq.mi.)	Population 1960 census	Population 1965 est.	Principal town
Curaçao	173	125,181	136,289	Willemstad
Aruba	69	58,743	59,415	Oranjestad
Bonaire	95	5,812	6,908	Kralendijk
St. Martin (Dutch part)	17	2,728	4,243	Philipsburg
Saba	5	980	1,019	Bottom
St. Eustatius	12	1,014	1,222	Oranjestad
Total	371	194,458	209,086	

The Southern Islands.—These islands are generally low, though hills rise to 1,230 ft. in Curaçao, 787 ft. in Bonaire and 617 ft. in Aruba. They consist mainly of igneous rocks and are fringed with coral reefs. Temperature varies little from an annual average of 27° C. (81° F.) and the heat is tempered by the easterly trade winds. The islands lie west of the hurricane zone. Rainfall is low and variable, often less than 20 in. a year, and the vegetation, much overgrazed by animals, is sparse. Cacti and other drought-resistant plants abound.

This group was discovered in 1499 by Alonso de Ojeda and settled in 1527 by the Spanish. The native Carib Indians were exterminated, except on Aruba, where their descendants form nearly two-thirds of the population. The Dutch, attracted by salt deposits, occupied the islands in 1634 and, except for brief British occupation in 1800 and 1807–16, they have remained Dutch possessions. The population is racially mixed and speaks Dutch (the official language), English, Spanish and Papiamento, a local patois composed of European and African words.

Through much of the 17th and 18th centuries the islands prospered from Dutch trade in slaves, plantation products and contraband, but they declined from 1816 until 1914, when the opening up of the Venezuelan oil fields turned the economic tide. A large oil refinery was opened in 1918 on Curaçao. Another began operating in Aruba in 1930, and by the 1960s was one of the largest in the world. The industry is now the economic mainstay of the islands, employing more than one-third of the working population and providing over 98% by value of all exports. The tourist industry and the entrepôt trade of the free ports of Curaçao and Aruba are also significant.

The Northern Islands.—These islands consist of volcanic rocks rising to 1,266 ft. on St. Martin, 1,968 ft. on St. Eustatius and 2,821 ft. on Saba. The climate is similar but rainfall is greater and hurricanes occur. They were first settled by Europeans between 1625 and 1640. Plantations of sugar and cotton were established on St. Martin and on St. Eustatius, which later became an entrepôt comparable to Curaçao. Saba, with precipitous slopes and no harbour, had no commercial value. Most of the population now engages in small-scale agriculture, but many men leave to work in the oil refineries in the southern islands. English is the principal language.

Administration.—The Netherlands Antilles are an integral part of the kingdom of the Netherlands. Executive authority is vested in the governor, appointed by the crown, and in a council of ministers of 7 members. They are responsible to the legislature (*staten*) of 22 members (12 from Curaçao, 8 from Aruba, 1 from Bonaire and 1 from the northern islands) elected by universal suffrage.

NETLEY, a village in Hampshire, Eng., about 6 mi. S.E. of Southampton by road (4 mi. by ferry), is situated in the parish of Hound and on Southampton water. There are extensive and picturesque Early English remains of the abbey founded in 1239 by Henry III and colonized by Cistercian monks from Beaulieu. The modern Netley Castle Convalescent home incorporates parts of one of Henry VIII's south coast forts. The Royal Victoria Military hospital is now the army's mental hospital; the original red-brick building (1856–63), with corridors a quarter of a mile long, is no longer used as an infirmary. Netley Marsh is another village about 5 mi. W. of Southampton. (A. G. G.)

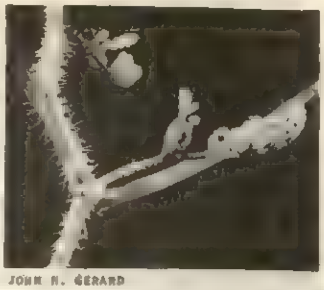
NETSCHER, CASPAR (1639–1684), painter of the Dutch school, was born at Heidelberg in Germany. His father died soon afterward and his mother moved to Arnhem, where his first master was Hendrick Coster. Later he was a pupil of Gerard Terborch and a copy, dated 1655, of Terborch's "Paternal Advice" already displays full technical mastery. In 1658 or 1659 he set out by sea for Rome, but went no farther than Bordeaux, where he was married in 1659. By 1662 he had returned to the Netherlands and settled in The Hague, where he spent the rest of his life, after establishing a fashionable practice as a portrait painter. He died on Jan. 15, 1684.

His most satisfying works are the earlier genre pieces, which maintain a high standard within the traditions of Terborch, from whom he acquired great skill in rendering textures, and of Gabriel Metsu. The "Lace Maker" in the Wallace collection, London, is a fine example. Though superficially elegant, the later biblical and mythological subjects and the small, glossy portraits that made his reputation in his lifetime are mostly deficient in true feeling or perception.

Netscher's sons THEODOR (1661–1732) and CONSTANTIJN (1668–1723) were among his many pupils and imitators. (R. E. W. J.)

NETTLE, the common name given to several plants with stinging hairs belonging to the family Urticaceae, especially to the genus *Urtica* and a few related genera. *Urtica* contains about 35 species of wide distribution. Three are found in the eastern United States, mostly as weedy plants introduced from Eurasia. The commonest is the stinging or great nettle (*U. dioica*) a cosmopolitan weed, often troublesome. Equally stinging is the native wood nettle (*Laportea canadensis*), found in rich woods throughout eastern North America. As in all nettles the stinging quality (which is not lasting, except in some tropical relatives) is caused by minute quantities of formic acid secreted in the extremely sharp-pointed hairs, which upon entry into the skin set up

instant irritation. In treelike Australian relatives (*Laportea*), the effect may last for months and has been credited with the ability to kill a horse by inducing a sudden rage.



JOHN H. GERARD
WOOD NETTLE (LAPORTEA CANADENSIS)

In southern and western United States there are other nettles, among them *U. chamaedryoides* of the southeastern states, *U. holosericea* of the western states and the closely allied western nettle (*Hesperocnide tenella*) of California.

Three species of nettle are wild and abundant in the British Isles and across Europe: the stinging nettle (*U. dioica*), a hairy perennial with male and female flowers on separate plants; the small nettle (*U. urens*), which is annual, has male and female flowers on the same plant and is also often a naturalized weed in North America; and the Roman nettle (*U. pilulifera*), also an annual, largely restricted to southern Europe. The small nettle (*U. urens*) once had some use as a fibre.

The eradication of the annual species of nettle can be accomplished by cutting off the tops before flowering, to prevent the setting of seed. The perennials are more difficult to eradicate; spraying with 2,4-D in bright weather or with chlordane provides the most effective control (*see* also WEED: *Control of Weeds*).

(N. TR.; X.)

NETTLE TREE, the name sometimes applied to certain trees of the genus *Celtis*, belonging to the elm family (Ulmaceae), especially to *C. australis*, common in Eurasia and northern Africa. The best-known species have usually obliquely ovate or lance-shaped leaves, toothed, rough-hairy above and marked by three prominent veins. The flowers are inconspicuous; the fruit is succulent, drupelike, a character that serves to separate the genus from the elms. It is a rapidly growing tree, from 30 to 40 ft. high, with a remarkably sweet fruit, recalling a small black cherry, and was one of the plants to which the term lotus was applied by Dioscorides and the older authors. The wood, compact and hard like its North American relative, the hackberry (*q.v.*), is used for many purposes.

The Australian nettle or stinging tree and the wood nettle of eastern North America belong to the family Urticaceae (*see* NETTLE).

NETWORK THEORY is a branch of engineering theory concerned with the evaluation of the properties of interconnections (networks) of basic components and with the synthesis of such interconnections for prescribed system characteristics. Network theory has been developed primarily by electrical engineers, particularly for the design of the systems for electrical power distribution and telephone transmission, but has subsequently been applied to the design or understanding of systems for water and gas distribution, industrial automation, missile and vehicle guidance and control, and automobile or aircraft traffic control. Other applications include such systems as those involved in the spread of communicable diseases and in various human functions such as seeing and hearing. The three elements of network theory are analysis, synthesis and identification.

1. Analysis is the evaluation of the properties of a given system; *e.g.*, the determination of the behaviour of an electrical power distribution system involving thousands of individual components including local loads, distribution lines, generators and protective devices. A typical analysis problem is the determination of the performance of the system when a short circuit occurs at one point.

2. Synthesis is the design of a system for specified performance. A classical problem in network synthesis is the design of electric circuits to separate 480 telephone conversations carried simultaneously on a single cable. At the sending end, the signals are combined by shifting each to a different portion of the frequency spectrum. With normal speech involving frequency components from 100–4,000 cycles per second (c.p.s.), one signal is transmitted from 0–4,000 c.p.s., one from 4,000–8,000 c.p.s., one from 8,000–12,000 c.p.s., and so on. At the receiving end, the signals must be separated by electrical networks, each of which transmits only one of the incoming messages.

3. Identification is the determination of a mathematical or analytical model from measurements of an actual system. For example, the dynamic characteristics of an airplane are measured by firing a bullet from the craft and observing the oscillation which results from the reaction force; or the characteristics of an industrial process can be evaluated by feeding into it a small randomly varying signal; or an automobile driver can measure road conditions and vehicle dynamics by continual small perturbations of the steering-wheel position.

Historically, network theory has developed from the work in classical mechanics by I. Newton, J. L. Lagrange and W. R. Hamilton, and the original studies of electric circuits by G. R. Kirchhoff. Until the advent of transcontinental telephone systems at the beginning of the 20th century, network theory emphasized the dynamic properties of vibrating mechanical systems. The field is now a central element of electrical engineering, with fundamental contributions in synthesis aspects from Ronald Foster, Wilhelm Cauer, O. Brune and S. Darlington. The rapid technological development during and following World War II included an expansion of network theory to encompass nonlinear networks (with analysis based on the work in nonlinear mechanics by L. Poincaré in France and by P. P. Lyapunov, A. N. Krylov and N. Bogoliuboff in Russia), feedback networks (with work developing from the pioneering efforts of H. S. Black, H. Nyquist and H. W. Bode at the Bell Telephone laboratories during the 1920s and 1930s), and such diverse areas as switching circuits and finite automata.

The basic analytic techniques of network theory are concerned with the evaluation of mathematical models (*e.g.*, sets of differential equations or the response of the system to a specified input signal) for the interconnection of the basic electrical components: resistors, capacitors, inductors, transformers, and voltage and current sources. Analysis is based on Kirchhoff's two laws which state that (1) the instantaneous sum of the currents entering any node of the network must be zero, and (2) the instantaneous sum of the drops in voltage around any closed loop must be zero. When these two laws are combined with the voltage-current relation for each element, differential equations can be written for the system without the direct utilization of the principle of the conservation of energy. The number of equations which must be written to describe network behaviour and the particular equations which can be used are determined from considerations of mathematical topology. Network theory also includes a large number of theorems which permit simplification of the analysis in many special cases of importance.

In the basic synthesis problem, with the input and output signals given, a network is to be realized by a suitable interconnection of the available components. In 1931 Brune showed that any specified driving-point impedance function (the ratio voltage to current at a single pair of terminals) can be realized if the impedance is a positive real function of the complex frequency s. In subsequent work, the necessary and sufficient conditions were established for the realization of a wide variety of different network functions (*e.g.*, the ratio of output voltage to input voltage, and the ratio of output current to input voltage).

Network theory has been extended to the study of feedback configurations, systems in which a portion of the output signal is compared with the input, with the difference used to control the output. Such systems are fundamental in automation (*q.v.*) and automatic control since the accuracy of the over-all transmission (the ratio of output to input) can be made insensitive to changes in the characteristics of the motor element. As a result of this insensitivity, engineering systems can operate properly even when the environment varies radically (*e.g.*, as the weather around an aircraft changes, as a space vehicle passes from outer space into the relatively dense atmosphere or as the road conditions for an automobile vary from dry to icy).

The analysis and synthesis of feedback systems is complicated by the stability problem, which is fundamental in network theory. Physical systems may oscillate out of control either because of

the feedback of energy from the output to a preceding point in the system (as in the case of ataxia observed in a man when he is an element of a feedback loop), or because of excitation of the system at its natural resonant frequency. (As a motor is brought up to speed, uncontrolled vibrations occur if the motor resonates at a frequency lower than the normal operating frequency.) Mathematical tests for stability in linear time-invariant systems (systems described by linear differential equations) were formulated by E. J. Routh in 1883 and for feedback systems by Nyquist in 1928. Fundamental contributions to the much more difficult problem of the stability of nonlinear systems have been made by Poincaré and Lyapunov, but the general problem of stability analysis and associated design techniques to insure stability still provide fundamental research problems in network theory.

Balabanian, *Linear Network Analysis* (1959); E. A. Guillemin, *Synthesis of Passive Networks* (1957); D. F. Tuttle, *Network Synthesis* (1958). (J. G. Tl.)

NEUBER, (FRIEDERIKE) CAROLINE (née Weissenborn) (1697–1760), one of the earliest and best-known German actress-managers, was born in Reichenbach, Saxony, March 9, 1697. The family moved to Zwickau when she was five. Rebelling against her tyrannical father, she ran away with a young clerk, Johann Neuber, at the age of 20 and married him in 1718. They served their theatrical apprenticeship in the traveling companies of Christian Spiegelberg (1717–22) and Karl Caspar Haack (1722–25), and in 1727 formed their own company, being granted a patent by the elector of Saxony, Augustus the Strong, to perform at the Leipzig Easter Fair. As early as 1725 her acting had attracted the attention of Johann Christoph Gottsched (*q.v.*), the critic and drama reformer who modeled his work on classical French tragedy and comedy. "Die Neuberin," as he came to call her, substituted in her company the careful learning of parts and rehearsal by the actors for the highly improvised farces and harlequinades that then dominated the German stage, and she elevated the moral tone of her company's lives. The collaboration of Gottsched and the Neuberin, which lasted until 1739, when they fell out, is usually regarded as the turning point in the history of German theatre and the start of modern German acting. The Neuber company found, upon returning to Leipzig in 1737 after three years of engagements in other German cities, that their patent, after the death of Augustus in 1733, had gone to the company of Johann Ferdinand Müller, a proponent of the old improvisations and harlequinades. The Neuberin reacted by burning Harlequin on stage to announce his dismissal. The company never regained its hold, however—the popularity of musical shows adding to the difficulty, and musical interludes between the acts not proving enough to offset the musical shows. In 1740 the Neuber company accepted an invitation of the Empress Anna to appear in St. Petersburg (later Leningrad); but the empress died in 1741, and though the company had introduced modern theatre to Russia, by the time it returned to Leipzig, Gottsched had allied himself with another company. His difference with the Neuberin intensified: she replaced the togas he had specified for his *Sterbenden Cato* with flesh-coloured tights; he attacked her in his reviews; she represented him in a prologue as a bat-eared censor; an obscene pamphlet in reply cast aspersions on the actress' private life.

In 1747 she quit the stage but in the following year returned with a new company, which successfully presented Lessing's first play, *Der junge Gelehrte*. Indifferent success, however, dogged the company as it played at Dresden, Frankfurt, and Warsaw, as well as Leipzig. In 1753–54 the Neuberin attempted to establish herself at Vienna, but failed; and the outbreak of the third Silesian War (1756), her husband's death (1759), and the bombardment of Dresden (1760) forced her to leave. She died in a peasant's hut at Laubegast near Dresden on Nov. 30, 1760; and although she was refused burial in holy ground, a monument to her was erected in the town in 1776, commemorating her as "the foundress of good taste in the German theatre." She had already been immortalized as Madame Nelly in Goethe's *Wilhelm Meister*.

See P. Wurche, "Der Schritt in die Kunst: die Neuberin und die Gottscheds," in *Theater der Zeit*, IX (1954). (A. M. N.; X.)

NEUBRANDENBURG, a town of Germany, headquarters of the *Bezirk* (district) of the same name which after partition of the nation following World War II became part of the German Democratic Republic. It lies at the outflow of the Tollense See about 134 km. (83 mi.) N. of Berlin and is a rail and road junction. Pop. (1964) 37,394. Neubrandenburg was incorporated in 1248. It was severely damaged in World War II, and of many medieval brick buildings only a few remain. It became a district capital in 1952. Since then it has been much rebuilt and has a new town centre. Manufactures include foodstuffs, building materials, paper, agricultural machinery, chemicals and leather.

NEUCHÂTEL, a canton and town of western Switzerland situated in the central Jura; the loftiest summit of the area is Mont Racine, 4,731 ft., in the Tête-de-Ran range. The canton, with an area of 308 sq.mi., most of which is reckoned productive, had an estimated population of 160,000 in 1965 (about two-thirds Protestant and one-third Catholic, all French-speaking). It consists, for the most part, of the longitudinal ridges and valleys characteristic of the Jura (*q.v.*), while its drainage is unequally divided between the Lake of Neuchâtel (leading to the Rhine) and the Doubs river (leading to the Rhône). The canton can be divided into three regions: (1) an area along the shore of the lake, called Le Vignoble (from its vineyards), which varies from about 1,500 ft. to 2,300 ft. above sea level; (2) an intermediate region, Les Vallées, consisting of the two principal valleys of the canton (the Val de Ruz, watered by the Seyon, and the Val de Travers, watered by the Areuse) which lie at a height of about 2,300 ft. to 3,000 ft. above sea level; and (3) the highest region, known as Les Montagnes Neuchâteloises (3,000 to 3,500 ft.), and mainly composed of the long valley in which stand the industrial centres of La Chaux-de-Fonds (*q.v.*), Le Locle, La Sagne, Les Ponts-de-Martel and La Brévine.

The main railway line, Paris-Pontarlier-Neuchâtel-Bern-Interlaken-Milan, traverses the canton while La Chaux-de-Fonds and Le Locle are connected by rail with Morteau and Besançon in France. Other lines link Neuchâtel, the cantonal capital, with La Chaux-de-Fonds and Le Locle, as well as with Lausanne (for Geneva and the Valais to the south) and Biel (for Basel and Zürich to the north). There are also a number of local railways. The canton is served by an excellent road network.

The most valuable mineral product is asphalt, concentrated in the Val de Travers. The wine of Le Vignoble is plentiful and of excellent quality. The most characteristic industry is watchmaking, which has been prominent since the early 18th century in the highland valleys of La Chaux-de-Fonds, Le Locle and Fleurier.

The canton is divided into 6 administrative districts, which comprise 62 communes. All elective offices are held for four years. The legislature or *grand conseil* consists of members elected in proportion to population, and the executive or *conseil d'état* consists of five permanent *conseillers*. The canton in 1963 sent five representatives to the national council (*Nationalrat*), the lower chamber of the Swiss parliament. It sends, as do all the other members of the Confederation, two members to the council of states (*Ständerat*), the upper chamber.

History.—Novum Castellum (Neuchâtel) was first recorded in the will (*loll*) of Rudolf III, the last king of Burgundy, on whose death (1032) that kingdom reverted to the western empire. About 1034, Conrad II, the Salic emperor, gave the town and its territories to Ulrich von Fenis, count of a neighbouring fief, and although the numerous medieval feudal divisions cannot be traced in modern political geography, the nucleus of Neuchâtel canton was then created. The dynasty gradually increased its dominions, so that by 1373, when Count Louis died, it held practically all the area occupied by the present canton, with the exception of the lordship of Valangin, which was held by a cadet line of the house till about 1592. The dynasty ended with the death of Count Louis' daughter, Isabelle, and the estate was inherited by her nephew, Conrad, lord of Freiburg im Breisgau in the German Rhineland. During Isabelle's reign, in 1406, Neuchâtel entered into union with Bern, and therein played an important part in shaping Swiss destiny. In 1504 it passed through marriage to the

ducal house of Orléans-Longueville. The Reformation was introduced there by Guillaume Farel (*q.v.*) in 1530. It became a principality and remained a possession of Orléans-Longueville until 1707, when that house became extinct. A struggle arose as to the succession and, finally, the parliament of Neuchâtel decided in favour of Frederick I, the first king of Prussia. The nominal role of the Prussian king (for the country enjoyed practical independence) lasted until 1848, with a brief interval from 1806 to 1814, when the principality was held by Marshal L. A. Berthier by virtue of a grant from Napoleon. In 1814 its admission into the Swiss Confederation was proposed and in 1815 it became the 21st canton and the only nonrepublican member. The hereditary rulers of Neuchâtel were the last to maintain their position in Switzerland. This anomaly led in 1848 to the establishment (attempted in 1831) of a republican form of government, brought about by a peaceful revolution. A royal attempt to regain power in 1856 was easily defeated and finally, after long negotiations, the king of Prussia renounced his claims to sovereignty. Consequently in 1857 Neuchâtel became a full republican member of the Swiss Confederation.

NEUCHÂTEL, the cantonal capital, is situated on the lake of the same name. Pop. (1960) 33,430, mainly Protestant and all French-speaking. The town is built partly on the slopes of Chaumont (3,871 ft.), and partly on land reclaimed from the lake, supplemented by the growth of alluvial deposits; later an artificial embankment added much ground, which is now the site of fine promenades, quays and a harbour, official institutions and schools.

The castle (dating from the 12th to the 16th centuries and now the seat of the cantonal administration) and the adjoining medieval Collegiate Church of Notre Dame (now Protestant) are built on a hill. They were originally founded when Ulrich II, count of Neuchâtel, took up his residence in the town, to which he granted in 1214 a charter of liberties. The Collegiate church contains the monumental tomb of the counts of Neuchâtel (erected in 1372). There are a number of fine 17th- and 18th-century patrician dwellings, including the Palais du Dupeyrou (1768), and fountains. The town hall (1782–90) is in classic style.

Among the buildings on the quays are the Collège Latin, with the public library (1835); the Musée des Beaux-Arts, with modern Swiss paintings and various antiquities (including the collection of P. J. E. Desor relating to old lake dwellings, and the notable collection of automated dolls created by Pierre Jaquet-Droz [1721–90] and his son Henri-Louis [1752–91]); a hall dedicated to Ferdinand Hodler; and a modern education centre comprising the university (founded as an academy in 1838), the gymnasium, the institute of physics and the Swiss Laboratory of Horological Research. (G. PD.)

NEUCHÂTEL, LAKE OF (Ger. NEUENBURGERSEE). The lakes of Neuchâtel, Biel (Bienne) and Morat, connected by canals, are survivors of a former glacial lake in the lower Aare valley. Neuchâtel is the largest lake wholly in Switzerland. Its total area is 83 sq.mi. divided among the cantons of Neuchâtel, Vaud, Fribourg and Bern (about 2 sq.mi.). It is about 23½ mi. long, from 3¾ to 5 mi. wide, its greatest depth is 502 ft., and its surface is 1,407 ft. above sea level. The Thièle or Zihl river enters at its southwestern end and issues from it at its northeastern end, but it also receives the Areuse and Seyon (northwest) and the Broye (northeast). On its southeastern shore is the picturesque and historic little town of Estavayer. At the southwestern extremity of the lake is Yverdon, the Eburodunum of the Romans and the residence (1806–25) of Johann Heinrich Pestalozzi, the humanist-educator. The northwestern shore is far more thickly settled, where from southwest to northeast the towns are Grandson, Cortaillod, Serrières and Neuchâtel itself. On the north shore is La Tène (*q.v.*), famous for prehistoric finds, which gives its name to the late Iron Age culture. There are steamer services between the lakeside towns.

NEUHOF, THEODOR, BARON VON (1694–1756), German adventurer, for a short time nominal king of Corsica, was born at Cologne on Aug. 24, 1694, the son of a Westphalian nobleman. Educated at the court of France, he served first in the French army, then in the Bavarian. Görtz, minister to Charles XII of Sweden, having discovered Neuhof's capacity for intrigue, sent him to England and to negotiate with Cardinal Alberoni in Spain, where he was made colonel and married one of the queen's ladies-in-waiting. Deserting his wife soon afterward, he went to France and became mixed up in John Law's financial affairs; then he wandered about Europe under various disguises. At Genoa he made the acquaintance of some Corsican prisoners and exiles, and persuaded them that he could free their country from Genoese tyranny if they would make him king of the island. With their help and that of certain merchants in Tunis he landed in Corsica in March 1736, where the islanders, believing that he had the support of several of the powers, proclaimed him king as Theodore I. He forthwith issued edicts, instituted an order of knighthood and waged war on the Genoese, at first with some success. He was soon defeated; civil war broke out in the island; and he left Corsica in Nov. 1736, ostensibly for foreign assistance. He returned to Corsica in 1738 and 1743, but in the face of combined Genoese and French hostility he attempted no military action. Imprisoned for debt in London, he regained his freedom by mortgaging his "kingdom" of Corsica and subsisted on the charity of Horace Walpole and other friends until his death in London on Dec. 11, 1756.

BIBLIOGRAPHY.—Accounts of Neuhof diverge greatly. The *Memoirs of Corsica* (1768) by "Colonel Frederick," who claimed to be his son but was apparently a Polish adventurer otherwise known as Vigliawischi (perhaps properly Wieloweyski), are misleading. *See* A. Le Glay, *Théodore de Neuhoff, roi de Corse* (1907); A. Vallance, *The Summer King* (1956).

NEUILLY, TREATY OF, the peace treaty concluded between Bulgaria on the one hand and the Allied powers and their associates on the other after World War I. Signed by the Bulgarian prime minister Aleksandr Stamboliski at Neuilly, outside Paris, on Nov. 27, 1919, it came into force on Aug. 9, 1920.

Territorially, Bulgaria's western frontier was adjusted in favour of the new Kingdom of Serbs, Croats and Slovenes, that is, the future Yugoslavia, which gained: (1) an area in the north, west of Vidin; (2) the town of Tsaribrod with adjacent areas, making any Bulgarian advance on Nish over the Pirot area more difficult; (3) the upper part of the Dragovishtitsa valley, due west of Sofia; and (4) the western half of the salient in the Strumitsa valley which Bulgaria had acquired under the treaty of Bucharest in 1913 (*see* BALKAN WARS). More serious, however, were Bulgaria's losses in the south, where not only a small area in the Rhodope mountains southwest of Pashmakli but also the whole of western Thrace had to be ceded to Greece, so that Bulgaria's immediate access to the Aegean sea at Dédéagatch, the country's major gain under the treaty of Bucharest, was forfeited. For ethnic reasons, however, Bulgaria received a slight accession of territory on the southeastern frontier, at Turkey's expense, in the area northwest of Edirne. Altogether, Bulgaria lost about 300,000 people, not all of them Bulgars.

Bulgaria was allowed to maintain a regular army of 20,000 men, together with 10,000 gendarmes and 3,000 frontier guards. This total of 33,000 was not enough to keep order in the country, which consequently suffered serious internal disturbances.

The clause of the treaty dealing with reparations constituted the most realistic approach to the matter in the peacemaking after World War I. No attempt was made to seize or to distribute the Bulgarian merchant marine; the amount to be paid was fixed at the lump sum of 2,250,000,000 gold francs; and a reparation commission, consisting of French, British and Italian representatives, eventually remitted 75% of the amount fixed; and the annual sum required to meet the charges on the outstanding 550,000,000 gold francs of the debt, payable over 60 years, was well within the capacity of the new Bulgarian state.

See H. W. V. Temperley (ed.), *A History of the Peace Conference*, vol. iv and v (1921).

NEUILLY-SUR-SEINE, a fashionable northwestern suburb of Paris, France, *département* of Hauts-de-Seine, stands on the right bank of the Seine river, 8 km. (5 mi.) west of Notre Dame cathedral, and on both sides of the Avenue de Neuilly. Pop. (1962) 72,570. It is chiefly residential, and notable for its large areas of open spaces, mainly the remains of former estates. The

18th-century bridge was rebuilt 1935–46. A large modern office building occupies the site of the château de Villiers. The château de Neuilly, a favourite residence of Louis Philippe I, was burned in riots in 1848. Neuilly is served by the Paris electric railway, the Métro. Perfumes, chemicals, medicines, plastic materials, automobile parts, electric fittings and aircraft are made on the outskirts and on the Ile de la Grande Jatte. (H. DE S.-R.)

NEUMANN, (JOHANN) BALTHASAR (1687–1753), German architect of diverse talents, a master of the late Baroque style, was born in Eger, Bohemia, in 1687. In 1709 he emigrated to Würzburg, where he learned his profession. Neumann designed palaces, housing, public buildings, bridges, a water system, fireworks, and more than 100 churches. He ran a glass factory, became a colonel of engineers, and was a professor of architecture. A stolid and conventional man, he produced works brilliant in design and elegant in engineering.

Neumann the dreamer would conceive the most intricate and original interiors; Neumann the builder realized them, achieving a maximum of security from a minimum of material. He directed squadrons of painters, sculptors, woodcarvers, iron founders, and landscape gardeners in creating the sumptuously harmonious decoration of his masterpieces. The Residenz Palace in Würzburg (1719–46), designed by Neumann and Germain Boffrand, is one of the great palaces of the Baroque period. Neumann's church of Vierzehnheiligen is a triumph in Rococo styling. Among his other works are the episcopal palaces of Bruchsal and Werneck and the pilgrimage churches of Neresheim and Käppele near Würzburg.

See Max H. von Freeden, *Balthasar Neumann* (1953). (J. P. C.)

NEUMANN, FRANZ ERNST (1798–1895), German mineralogist, physicist, and mathematician, made important contributions to the mathematical theory of electrodynamics by establishing laws of the induction of electric currents in 1845 (*see* PHYSICAL UNITS: *Electrical Standards*). He was born at Joachimstal on Sept. 11, 1798. In 1815 he interrupted his studies at Berlin to serve as a volunteer in the final campaign against Napoleon and was wounded. Subsequently he entered the University of Berlin as a theology student, but soon turned to scientific subjects. His earlier papers were mostly concerned with crystallography (*see* METEORITES: *Structure*), and the reputation he earned led to his appointment as *Privatdozent* (lecturer) at the University of Königsberg, where in 1828 he became extraordinary professor and in 1829 ordinary professor of mineralogy and physics.

Working with minerals, he extended to compounds in 1831 the Law of Dulong and Petit on the heat of elements, formulating Neumann's Law that a compound's molecular heat is the sum of the atomic heats of its constituents. His work in optics produced papers that place him among the early searchers after a dynamic theory of light. In 1832 he used the then popular theory of the ether (*see* LIGHT: *History: The Dynamical Theories of the 19th Century*) to calculate results agreeing with those obtained by A. L. Cauchy, and succeeded in deducing laws closely resembling those of A. J. Fresnel (*see* LIGHT: *History: The Age of Fresnel*). In subsequent years he attacked the problem of giving mathematical expression to the conditions that hold for a surface separating two crystalline media and worked out from theory the laws of double refraction in strained crystalline bodies (*see* SURFACE TENSION: *General Properties of Surface Tension*). His last publication, one on spherical harmonics, appeared in 1878. Neumann had a part in founding a notable seminar in mathematics and physics to give students practical acquaintance with the methods of original research. He retired in 1876 and died in Königsberg on May 23, 1895. His works were published in three volumes (1906–28).

See biographies by I. Neumann (1929) and A. Wangerin (1907).

NEUMANN, JOHN NEPOMUCENE (1811–1860), Bohemian-U.S. Roman Catholic bishop of Philadelphia, the first American Catholic prelate proposed for canonization (1886), was born in Prachatitz, Bohemia, on March 28, 1811. He studied at the *Gymnasium* at Budweis, the diocesan seminary of Budweis, and the University of Prague, emerging with a reputation for a clear, penetrating, analyzing mind and for solid piety. His zeal for the American missions took him to New York, where he was ordained priest in June 1836. Neumann joined the Redemptorists in 1840, his holiness of life and administrative abilities winning for him the post of superior of St. Philomena's parish in Pittsburgh, Pa., and later command of all Redemptorists in the United States. He became rector of St. Alphonsus' parish, Baltimore, Md., in 1851, and was named by Pope Pius IX in March 1852 to rule the see of Philadelphia. For eight years Neumann worked to build churches, schools, and asylums, legislating for his priests and people and visiting every corner of his spiritual domain. He combated trusteeism; was the first prelate to organize a diocesan school system; and introduced the diocesan-wide celebration of the devotion called the Forty Hours.

A deep personal love of God and a resolve to lead others to him were the goals of Neumann's life. He died on Jan. 5, 1860, and in 1921 Pope Benedict XV declared his virtues heroic. He was beatified Oct. 13, 1963.

See Michael J. Curley, C.SS.R., *Venerable John Neumann, C.SS.R.* (1952), with bibliography; Johann Berger, C.SS.R., *Leben und Wirken des hochseligen Johannes Nep. Neumann* (1883), Eng. trans. by Eugene Grimm, C.SS.R., *Life of the Right Reverend John N. Neumann* (1884).

NEUMANN, JOHN (JANOS) VON (1903–1957), U.S.-Hungarian scholar was an outstanding mathematician and a scientist of extraordinarily broad interest and competence who contributed to several disciplines. Born in Budapest, Hung., Dec. 28, 1903, he was a general scientific prodigy. In 1923 he received a doctorate in mathematics from the University of Budapest and a degree in chemical engineering from the Eidgenössische Technische Hochschule (Federal Institute of Technology) at Zurich, Switz. He was *Privatdozent* (lecturer) at the University of Berlin from 1926 until 1929 when he became an assistant professor at the University of Hamburg. A visiting lecturer at Princeton University, he became professor of mathematical physics there. Von Neumann was appointed professor of mathematics in the Institute for Advanced Studies when it was founded at Princeton, N.J., in 1933, a post he held until his death in Washington, D.C., on Feb. 8, 1957.

His international reputation was based on contributions to mathematical and physical theory, most notably: his invention of the theory of rings of operators (Von Neumann algebras), initiated in the late 1920s; his *Mathematical Foundations of Quantum Mechanics* (1926; Eng. trans., 1955); his elaborate theory (1923) of numbers as sets; and, with Oskar Morgenstern, his *Theory of Games and Economic Behavior* (1944). He well may be remembered longest for his work in pure mathematics during 1933–43 (*e.g., see* GROUPS, CONTINUOUS: *Hilbert's Fifth Problem*); and his work on the theory of operator rings (*see* OPERATORS, THEORY OF) represents a high point of the axiomatic and integrative tendencies characteristic of 20th-century mathematics. This work showed that analysis (*q.v.*) had interesting and unsuspected connections with algebra and geometry.

In addition to his teaching, in the late 1930s Von Neumann began work as a consultant for the U.S. Navy and Army. During World War II, his concept of implosion speeded development of the atomic bomb at Los Alamos, N.M. From 1945 to 1955 he was director of the federal electronic computer project, his efforts substantially expediting development of the hydrogen bomb. Appointed to the U.S. Atomic Energy Commission in 1954, he won its $50,000 Enrico Fermi Award in 1956. He continued work for the commission even after cancer confined him to Walter Reed Hospital from 1956 until he died.

Von Neumann's posthumously published *Theory of Self-reproducing Automata* (1966; ed. and completed by A. W. Burks) is an attempt to move from an understanding of the human nervous system to a general cybernetic theory that would generate an increasingly sophisticated computer technology. His *Collected Works* (vol. 1–3, 1961–62; vol. 4–6, 1963) reveal distinguished contributions to several other disciplines including: logic, theory of sets, quantum mechanics, ergodic theory, almost periodic functions in a group, continuous geometry, design of computers, numerical analysis, astrophysics, hydrodynamics, and meteorology. (I. E. S.; X.)

NEUMANN, THERESE (1898–1962), German stigmatic, was born in the Bavarian village of Konnersreuth as the eldest daughter of a country tailor on April 8, 1898. At the age of 20 she underwent a severe nervous shock through the outbreak of a fire and subsequently suffered from hysterical paralysis, blindness and gastric troubles for several years. In 1926 a blood-coloured serum began to ooze from her eyes, and during Lent of the same year the stigmata (wounds resembling those of Christ in hands, feet and side) appeared. Throughout the next 30 years these continued to bleed on many Fridays, especially in Passiontide, and were accompanied by trances and other striking phenomena which attracted many visitors. Following her stigmatization, Therese claimed to live without food or drink, being sustained only by Holy Communion. At the request of her bishop she was subjected to a fortnight's investigation in 1927. Later the church authorities recognized this to have been inconclusive, as hysterical subjects are known to be able to sustain a complete fast for more than three weeks; in 1932 and 1937 she was requested to submit to another examination but refused, alleging that her father forbade her to do so. Hence her bishop issued no more permits for visits to her, which nevertheless reached a new peak in the years after World War II, when U.S. soldiers and others came to Konnersreuth in large numbers.

After 1950 the Passion ecstasies became much less frequent, though she continued to be visited by thousands each year until her death at Konnersreuth on Sept. 18, 1962. The controversy about the supernatural or purely neurotic origin of the phenomena continues.

See H. C. Graef, *The Case of Therese Neumann* (1951). (H. C. G.)

NEUMES: *see* MUSICAL NOTATION.

NEUMÜNSTER, a town of Germany, *Land* (state) of Schleswig-Holstein, which after partition of the nation following World War II became part of the Federal Republic of Germany, lies 66 km. (41 mi.) N. of Hamburg by road. Pop. (1961) 75,045. Its name derived from *novum monasterium* ("new minster"), the church of the monastery that was founded in 1125 by the Augustine missionary Vicelin, known as the apostle of the Wends; St. Vicelin's church (1829) is in the town, which was chartered in 1870.

Neumünster, which suffered heavy air-raid damage during World War II, has been rebuilt on modern lines. There are many schools, including one for textile engineering, and a textile museum noted for its collection of ancient textiles. A large public park has a zoological garden for native animals. Neumünster is a rail and road junction on the main routes from Hamburg to Kiel and Denmark. More than half the inhabitants are employed in industry (textiles, leather, chemical fibres, switch gears and paper) and the Bundesbahn (Federal Railways) repair plant. (R. U.)

NEUNKIRCHEN, a town of Germany in the Saarland, which in 1957 became part of the Federal Republic of Germany, stands on the Blies, 20 km. (12 mi.) by road N.E. of Saarbrücken. Pop. (1961) 45,625. Blast furnaces and pit derricks dominate the town which is surrounded on all sides by extensive woods. In addition to many administrative buildings and a new town hall, there are a park with a zoo, sports grounds and one of the most modern indoor swimming baths in West Germany. Neunkirchen is a junction on the railway from Saarbrücken to Mainz and has the steepest tram (streetcar) route in Europe. The town is a centre of mining, industry, communications and of cultural life for eastern Saarland. Besides coal mines and ironworks there are sawmills, breweries and textile factories. Neunkirchen was first mentioned in 1281. There is evidence of early iron founding (1595) and ironworks rebuilt in 1652. The town gained civic rights in 1922. (K. F. H.)

NEUQUÉN, an inland province of Argentina on the Chilean frontier, between the Colorado and Limay rivers. Pop. (1960) 109,890; area 58,448 sq.mi. (94,079 sq.km.). The greater part of the territory is mountainous, with fertile, well-watered valleys and valuable forests. The eastern part, however, contains large plains showing only stunted vegetation and having numerous saline deposits. The long droughts that prevail in this region have deterred agricultural settlement. Nevertheless, agriculture and stock raising provide the chief sources of wealth. The temperature of the Andean region is cold even in summer, but on the lower plains the summer is hot. The Neuquén, which meets the Limay near the 68th meridian to form the Río Negro, is the principal river of the province. The largest of a group of beautiful lakes in the higher Andean valleys is the celebrated Nahuel Huapí (*q.v.;* lion grass), which lies partly in the southwestern angle of the province, and partly in Río Negro and Chile. It is the source of the Río Limay and receives the overflow from two smaller neighbouring lakes.

The territory of Neuquén, officially created in 1884, was promoted to the status of a province in 1955. The population is concentrated in a few small towns on the rivers and in some colonies in the fertile districts of the Andes. The provincial capital, Neuquén (pop. [1960] 16,738), was founded on Sept. 12, 1904. Near the capital is the Río Negro dam, source of irrigation for a large area. The province is reached by a light-draft river steamer which ascends the Río Negro to the capital, at the confluence of the Limay and Neuquén, and by railway from Bahía Blanca to Zapala, via Neuquén. (GE. P.)

NEURALGIA. A symptom, not a disease, neuralgia is manifested by pain along the course of a nerve. Various forms are distinguished according to the nerve affected: suboccipital neuralgia when the pain is in the back of the head and neck, intercostal neuralgia when it is between the ribs, etc. Strictly speaking, the term is restricted to those nerve pains for which no specific cause and no evidence of impaired function of the nerve can be found. Actually the word is often employed for pain caused by local nerve damage when pain is the prominent symptom. Most sciatic neuralgia, for example, is attributable to mechanical compression and stretching of a sensory root of the sciatic nerve from displacement of an intervertebral disc within the spinal canal. Neuralgic pain is frequently the forerunner of hidden organic disease, and the first consideration in treatment is the search for a definitive cause.

Characteristically the pain of neuralgia is sharp, acute, darting and paroxysmal. The attacks, commonly brief in themselves, may succeed each other without respite for hours or days, robbing the victim of appetite and sleep and reducing him to a state of exhaustion and mental depression. Neuralgia of a nonspecific kind tends to occur during states of debility and malnutrition from any cause and in association with infections. Exposure, chilling and fatigue are sometimes precipitating causes.

Treatment for relief of symptoms is sometimes of little use, many cases proving refractory to all measures. Pain is controlled, as well as can be, by ordinary analgesics, together with hypnotics if required for sleep, avoiding narcotics if at all possible. Hot or cold applications, diathermy or repeated local anesthesia with procaine hydrochloride (Novocaine) may be beneficial. For extremely severe or prolonged attacks, palliative operations on sensory nerves, roots or their central connections have been resorted to with differing success.

Trigeminal Neuralgia.—In this condition, also called *tic douloureux*, the pain is strictly confined to one or all of the three divisions of the main sensory nerve of the face. Pain appears in the lower jaw, cheek, tongue and temple, in the upper jaw, cheek and side of the nose or in the forehead, depending on the division affected. The flashing, stabbing, boring pains, usually lasting less than a minute, are excruciating, and the sufferer commonly recoils from his agony with a spasmodic facial contortion. Characteristically, stimulation of circumscribed areas of the face or mouth, eating, talking or even the lightest touch may provoke an explosion of neuralgic pain. There is little, if any, discomfort during the intervals between paroxysms. The condition, for which no cause can usually be found, afflicts the elderly by preference and may have spontaneous remissions. Medical therapy is undependable, but surgical treatment is effective. Injection of the affected branch with alcohol gives prompt relief but rarely for more than a year or two. Cutting of the sensory roots within the skull affords almost certain permanent freedom from pain.

Atypical Facial Neuralgia.—This differs from trigeminal neuralgia in that the pain, although felt in the face, tends to be more diffuse, is duller in quality, persists for minutes or hours and is not ordinarily provoked by sensory stimulation. The nature of

the condition is obscure but it seems probable that it is a disorder of the sympathetic nervous system and may be a variant of migraine (*q.v.*). Some cases respond to a regimen of treatment for migraine, but most are more intractable. All do poorly with surgical treatment. A variety of paroxysmal, unilateral nocturnal neuralgic pain involving the eye and temple, often called histamine headache in the United States, is a closely related condition.

Postherpetic Neuralgia.—This is merely the continuation for weeks, months or sometimes years of the nerve-root pain which is present in the region of the skin eruption during the acute stage of an attack of shingles. This distressing sequel of the disease affects mostly elderly persons. X-ray therapy appears to benefit some patients. Otherwise, once established, the pain stubbornly resists treatment. *See* SKIN, DISEASES OF. (R. B. R.)

NEURITIS (NEUROPATHY) denotes a disease of nerves. Characteristic of neuritis are pain and tenderness; impaired sensation, strength and areflexia; and abnormal circulation and sweating in the distribution of the diseased nerve or nerves. Neuritis of the special sense organs and viscera has other, but equally specific, characteristics.

A unique feature of the nerve cell is its extraordinary length. In its course a nerve may lie next to skin or bone; it may pass through muscles or tunnels; proximally its roots lie in relation to the spinal column and distally its fibres diminish in calibre. All these anatomic vicissitudes represent hazards. Nerve fibres are sites of elaborate enzymatic systems that can be blocked by toxins or can fail through lack of specific vitamins. Nerve fibres are richly supplied with blood vessels, and disease of these vessels may have devastating effects. Nerve fibres are housed in connective tissue that may become infected, scarred, edematous or invaded by tumours, events that may cause injury to nerve fibres. (*See* also NERVE; NERVOUS SYSTEM, DISEASES OF.)

There are many causes of neuritis, but in general it may be said that when neuritis affects one nerve (mononeuritis) or a plexus of nerves (plexitis) the cause commonly is a mechanical one; that when several single nerves are affected simultaneously (mononeuritis multiplex) the cause often is a vascular or allergic one; and that when nerves are affected diffusely (multiple neuritis) the cause often is toxic, metabolic, viral or allergic. Electromyography, a procedure by which changes in the electric potential of muscle may be recorded through stimulation of its nerve, is of decisive help in the diagnosis of neuritis.

Mononeuritis and Plexitis.—Bell's palsy (neuropathy of the facial nerve) often follows exposure to a draft. The facial nerve passes through a bony canal that can accommodate little more than the nerve and its attendant blood vessels, and in about two-thirds of the cases of Bell's palsy the nerve is injured here. If continuity of the fibres is interrupted, they must grow anew. Growing fibres and their branches often arrive at a wrong destination, and this results in extraneous movements that ever after betray an old Bell's palsy.

One of the nerves most commonly afflicted is the ulnar, which serves the hand and arm. In about two-thirds of the cases this nerve is injured at the elbow, where it lies between skin and bone. The nerve again becomes vulnerable at the wrist, and ulnar neuropathy therefore is conspicuous among the occupational neuropathies.

The median nerve, serving muscles of hand and forearm, carries large complements of sensory and vasomotor fibres and is especially intolerant of injury. The commonest cause of median neuritis is compression of the nerve in the carpal (wrist) tunnel. This is convincingly demonstrated by electromyography. Slight injury to the nerve at higher levels may result in a prolonged and distressing affliction of the hand known as causalgia.

The radial nerve spirals the humerus (the bone of the upper arm) immediately under the skin and here is subject to compression. The wrist and finger drop that results is sometimes called Saturday night paralysis. A small cutaneous branch of the radial nerve may be compressed at the wrist by the band of a wrist watch, with resulting chiralgia paraesthetica.

In at least half of 400 cases of neuropathy of the brachial plexus that were reviewed, the brachial plexus (the great nerve plexus of the neck and armpit, where meet all the nerves supplying shoulder, arm and hand) was injured by traction or compression. In a fifth of the cases, cancer of the breast or lung had invaded the plexus.

Involvement of the sciatic nerve (the great nerve supplying the thigh and leg) or its roots accounts for about 40% of cases of neuritis. Among the causes are protrusion of intervertebral disks, arthritis of the spine and trauma of the nerve itself.

Crossed leg palsy is caused by wedging of the common peroneal nerve (serving the anterior muscles of the leg) between the head of the fibula and the opposite knee. When prolonged squatting compresses the nerve between the head of the fibula and the tendon of the biceps femoris muscle, a foot drop results, sometimes called gardener's paralysis.

Numbness of the lateral aspect of the thigh because of neuritis of the lateral femoral cutaneous nerve is known as meralgia paraesthetica. The nerve usually is injured where it traverses or passes under the inguinal ligament.

Mononeuritis Multiplex.—When several isolated and even widely separated nerves are involved simultaneously, it is usually found that trouble has started within the nerve itself. This may occur in leprosy (*q.v.*), in serum paralysis, in periarteritis nodosa and in porphyria (*q.v.*).

Multiple Peripheral Neuritis.—This term (also polyneuritis or polyneuropathy) denotes diffuse and symmetrical involvement of nerves. Symptoms usually begin in the feet, then in the hands, then progress upward. The usual causes are bacterial, viral, chemical and metabolic poisons, allergy or the lack of substances that are needed to support the function of nerves. Associated with multiple neuritis may be the Guillain-Barre syndrome, in which the content of protein of the spinal fluid is elevated without increase in the number of cells.

Treatment of Neuritis.—The general principles of treatment include management of the underlying cause, care of the afflicted limbs, application of heat, adequate nutrition and physical therapy. Specific forms of therapy include the administration of BAL (2,3-dimercapto-1-propanol) in the treatment of arsenical polyneuritis; of EDTA (ethylenediaminetetraacetic acid) in the treatment of lead poisoning; of cortisone in the treatment of serum paralysis and the neuritides of collagen diseases; and of vitamins of the B complex in the treatment of neuropathies associated with poor nutrition. (H. W. WN.)

NEUROLOGY is the area of science that deals with the nervous system. *See* NERVE; NERVE CONDUCTION; NERVOUS SYSTEM; NERVOUS SYSTEM, DISEASES OF; NERVOUS SYSTEM, SURGERY OF.

NEUROLOGY, COMPARATIVE. The field of comparative neurology comprises the nervous mechanism and activities of all animal types, from the most primitive to man. Nearly all living organisms are sensitive to sudden changes in environmental conditions. This property of sensitivity is one of the fundamental characteristics of living matter and is termed irritability. Changes in environment, which may be of many kinds, act as stimuli; because of the irritability of living matter, a stimulus results in some form of response that usually is advantageous to the organism.

Introduction.—Stimuli as a rule are localized as to point of impact, and all animals except the lowest forms possess special cells or aggregations of cells for the reception of different types of stimuli. Such specialized cells are called receptors; in their most elaborate form, such as the eye and the organ of hearing of higher animals, they constitute the special sense organs. Both in man and in lower animals there are many types of simpler organized receptors that are activated by a variety of external and internal stimuli including touch, temperature changes, chemical substances, pain-producing contacts and contraction of muscle. The stimulus typically produces a change in the part of the cell to which it is applied or in the receptor, and is followed by a wave of change that progresses to points distant from that of impact.

The power of transfer of an impulse initiated by a stimulus is called conductivity and represents another characteristic of living matter. All living cells probably possess it in some degree, but

nervous tissue is especially adapted for the reception and conduction of stimuli. The response may be accomplished by another part of the same cell, which may or may not be modified for that purpose, or by specialized cells connected with the receptors by conducting fibres. The structure that has the capacity for response is called the effector.

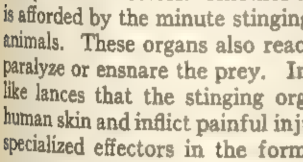
FIG. 1.—SIMPLE RECEPTOR-EFFECTOR SYSTEM

INVERTEBRATES

Protozoans.—These animals consist of a single cell. Some protozoans possess a system of delicate threads or fibrils that interconnect the bases of whiplike locomotory cilia. These fibrils centre in a small body, the motorium, which is situated near the gullet. Co-ordinated movements of the cilia adapted to propel the animal forward or backward indicate the presence of a special conducting mechanism; this is provided by the fibrils, which constitute a primitive neuromotor system.

Sponges.—In sponges, which consist of many cells, no nervous structures have been identified. These animals have a system of channels with inlet and outlet pores through which a current of water may pass through their bodies. Minute organisms that serve for food are extracted from the water by cells lining the channels. The chief movements of sponges consist of opening and closing the pores that govern the circulating stream. These movements are accomplished by very simple contractile cells that appear to be activated by direct stimulation without the intervention of nervous elements. Such musclelike elements have been designated independent effectors. Another example of an independent effector is afforded by the minute stinging organs of jellyfishes and related animals. These organs also react directly to stimuli and serve to paralyze or ensnare the prey. In the larger jellyfishes the threadlike lances that the stinging organs discharge can penetrate the human skin and inflict painful injuries. In the higher animals more specialized effectors in the form of muscles, glands and electric organs are activated by impulses transmitted to them by nervous tissue.

Coelenterates.—The coelenterates, jellyfishes and related animals, also possess effectors in the form of well-differentiated muscles, whose cells can change their shape rapidly. Certain of these muscles may respond directly to stimuli but as a rule muscle responds to a nervous impulse. In the tentacles of sea anemones and related animals a simple receptor-effector apparatus is found that consists of a sensory cell and muscle.



ADAPTED FROM G. H. PARKER, "THE ELEMENTARY NERVOUS SYSTEM," J. B. LIPPINCOTT COMPANY, PHILADELPHIA, 1919

FIG. 2.—COMPLEX RECEPTOR-EFFECTOR SYSTEM OF SEA ANEMONE

The sensory cell reaches the external surface and constitutes a receptor. The receptor is stimulated by mechanical impact or by dissolved substances, such as meat juices, in the water. The deep part of the receptor cell gives rise to a fibrous process that serves as a conductor. This process has numerous branches that form a plexus in the layers beneath the surface and end in relation to the muscles in the deep layers. The plexus spreads the stimulus so that a widespread response of muscle is produced from a localized stimulus. This response results in movements of the tentacles to carry food to the mouth. The combination of specialized receptor cells and muscle makes possible relatively quick movements in response to slight stimuli.

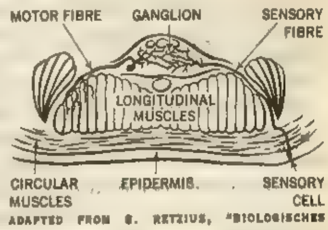
A further elaboration of the receptor-conductor-effector apparatus, found in hydroid polyps, sea anemones and jellyfishes, includes primitive nerve cells and their processes which are interposed between the receptors and effectors. Each of these primitive nerve cells has numerous branching fibres that form an intricate plexus beneath the surface of the animal and penetrate to internal structures. There is good histological evidence that the processes of the nerve cells do not fuse but only interlace or run parallel with each other. They have points of contact at which the nerve impulse is transmitted from one fibre to another. Such a point of contact between individual nerve cells or their processes is known as a synapse.

Synaptic junctions are characteristic features of the nervous systems of higher animals, and in these animals they serve as one-way valves that transmit impulses in only one direction. In the jellyfishes, however, transmission may be in either direction. An impulse initiated at any point, accordingly, may spread through the entire nerve plexus to all parts of the body, in contrast with the manner of its spread in the greater part of the nervous system of higher animals in which the one-way synaptic connections direct the impulses into specific channels.

Higher Invertebrates.—The nervous system of animals above the jellyfishes assumes such a variety of forms that only a few examples can be given. In all of the bilaterally symmetrical animals, however, it is made up of specific nerve cells, which, with their processes, long and short, are known as neurons. Typically the cell bodies are grouped into masses called nerve centres, whereas the longer processes are collected into bundles in a central nervous axis that connects the nerve centres with each other and into peripheral bundles known as nerves. The nerve centres and connecting bundles form a central nervous system. The nerves connect the peripherally or internally situated receptor and effector organs with the central nervous apparatus.

As represented in segmented invertebrates such as the earthworm and the insects, the central nervous system comprises an anterior collection of nerve cells and fibres, usually called the brain, and two elongated strands of nerve fibres and groups of cells extending throughout most of the length of the body.

The groups of nerve cells, called ganglia, constitute nerve centres that occur in pairs, one pair for each body segment. Each pair is interconnected by short transverse bundles of nerve fibres so that a ladderlike pattern of the central nervous system results. The brain is situated in the head region, above the digestive tube, but is connected to an enlarged nerve centre at the anterior end of the nerve cord by a strand of nerve fibres that passes downward on either side of the forward part of the alimentary canal. In the invertebrates the nerve cord lies beneath the digestive tract.



ADAPTED FROM G. RETZIUS, "BIOLOGISCHES UNTERSUCHUNGEN"

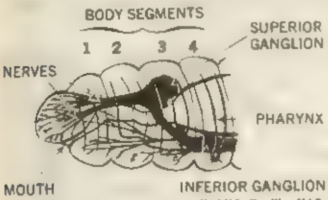
FIG. 3.—TRANSVERSE SECTION THROUGH VENTRAL BODY WALL AND A GANGLION OF CENTRAL NERVOUS SYSTEM OF THE EARTHWORM

Earthworm.—In the earthworm a pair of ganglia occurs in each of the segments of the body. From these ganglia, and from the brain, nerves pass to the adjacent body parts, to the muscles and to the skin. The earthworm has sensory cells in the skin, especially in the anterior part of the body. The outer ends of these cells reach the external surface and are modified as receptors. Their inner ends are elongated as small nerve fibres that collect together to form nerves, which extend to the nerve centres. Within the latter these fibres make synaptic connections with the cell bodies, or their processes, of a second set of neurons whose long fibres become included in the nerves and are distributed to muscle. A stimulus applied to the skin may produce a muscular movement, the nervous mechanism involved consisting of receptor or sensory neuron, connections in the nerve centre and an effector or motor neuron. Such a chain of neurons from receptor to effector constitutes a reflex arc, the simplest comprising two elements and their synaptic connection in the nerve centre.

A third type of neuron situated between the sensory and the motor neurons is also found in the earthworm. It is known as the internuncial neuron and serves as an adjustor. Such neurons occur only within the brain and the nerve cord and its centres, extending lengthwise from one nerve centre to another and conduct-

ing impulses that influence the activities of segments of the body remote from the point of stimulation.

Even in the worms there is some degree of control by the anterior nerve centres over other parts of the nervous system. After the brain of an earthworm is removed the animal can eat and crawl, right itself and perform other functions normally. It is restless and active, however, its anterior segments are lifted upward and it requires a much longer time to burrow than the normal worm.



ADAPTED FROM A. E. SHIPLEY AND E. W. MACBRIDE, "ZOOLOGY," 3RD EDITION. BY COURTESY OF CAMBRIDGE UNIVERSITY PRESS

FIG. 4.—SIDE VIEW OF BRAIN AND ANTERIOR NERVES OF THE EARTHWORM

Marine Clam Worm.—The clam worm, *Nereis,* whose nervous system is built on the same general plan, has few sensory cells in the skin but possesses several pairs of eyes and feelers and tentacles that are stimulated by chemical substances. These all are attached to the head region and their nerves are connected with the brain. When the brain is removed, the animal loses sensitivity to light and chemical changes; it ceases to feed and to burrow and it becomes overactive.

Much more definitely than in the earthworm the brain of the clam worm is a sensory centre that normally exercises a restraining control over the chief motor centres. These centres, situated in a nerve centre beneath the gullet, have connections with the segmental nerve centres.

FIG. 5.—NERVOUS SYSTEM OF HORSEFLY

Insects.—Some of the activities of many animals are instinctive. Much of the behaviour of insects is of this type. Such animals have no basis of learning but rest on a structural pattern of the nervous system which is preformed in each individual. Instinctive acts require only an appropriate stimulus to start them but are much more complicated than reflexes.

Bees, for example, build their combs and do other things instinctively and without training, but their nervous system also is adaptable to some degree so that they can learn to find their way and are helped by their fellows. Even higher animals perform many instinctive acts, such as the suckling of young mammals or the crying of a newborn infant.

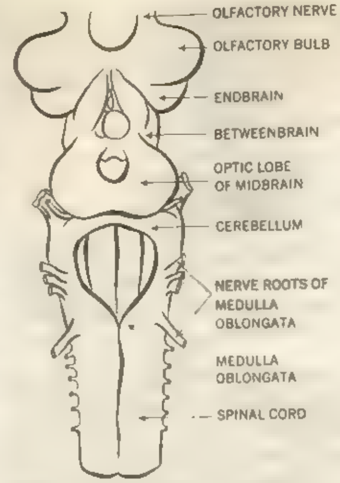
FIG. 6.—BRAIN OF HAGFISH

VERTEBRATES

The central nervous system of the vertebrates (animals with spinal axis of cartilaginous or bony segments) consists of a spinal cord surrounded by the vertebrae and a brain situated in the head.

Spinal Cord.—The spinal cord is largely a reflex organ but is influenced by impulses from the brain centres. It also relays to the brain sensory impulses brought by the spinal nerves. In mammals the motor activities of the cord are more strongly influenced by the brain than in lower vertebrates. In addition there is a voluntary motor pathway, originating in the cerebral cortex, the impulses of which result from integrations at the highest levels of the nervous system rather than at reflex levels.

The relative functional importance of the sensory and some of the motor systems of the brain varies in different species. Also many water vertebrates, such as fishes, have a special system of sensory organs and nerve centres, the lateral line system, that is lacking in air-breathing animals. The relative size of the nerve centres of the brain corresponds with the importance of such centres to the different groups of animals; for example, in birds, which have extremely good visual powers, the optic centres are large, whereas the lateral line centres are absent.



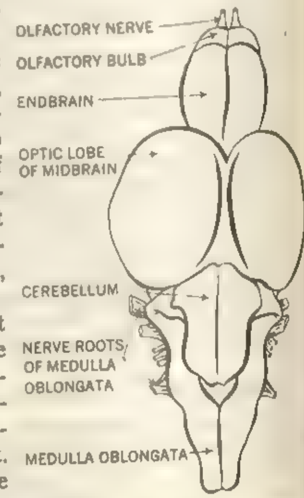
ADAPTED FROM O. LARSELL, "JOURNAL OF COMPARATIVE NEUROLOGY," VOL. 86, PP. 359–446, 1947

FIG. 7.—BRAIN OF LAMPREY

Through observation and experimental studies most of the functional regions and related fibre bundles of the vertebrate brain have been determined and their activities investigated.

Brain.—In all animals from the worms and insects to the highest forms the brain is an important and characteristic part of the nervous system. It is always situated at the anterior end of the animal and with it are connected the principal sense organs of the body. In man and other higher animals the brain is thus associated with the organs of sight, hearing, smell and taste. The development of these special receptors and of the brain has progressed hand in hand in the evolutionary process. This process has involved transformation of several of the sense organs of the head from surface receptors, which require contact of the stimulus with the body surface, to distance receptors, the stimuli of which come from more or less remote points although they must impinge on the specialized structures, such as the eye or the ear, to be effective.

There is reason to believe that the distance receptors have evolved from the contact receptor type and with this transformation the brain has also undergone a far-reaching development. As the distance receptors become increasingly important the brain becomes a more complex switchboard to meet the needs of increased sensory reception. With the development within it of more and more internuncial neurons the brain becomes in the higher animals the centre for increasingly complex nervous activities.



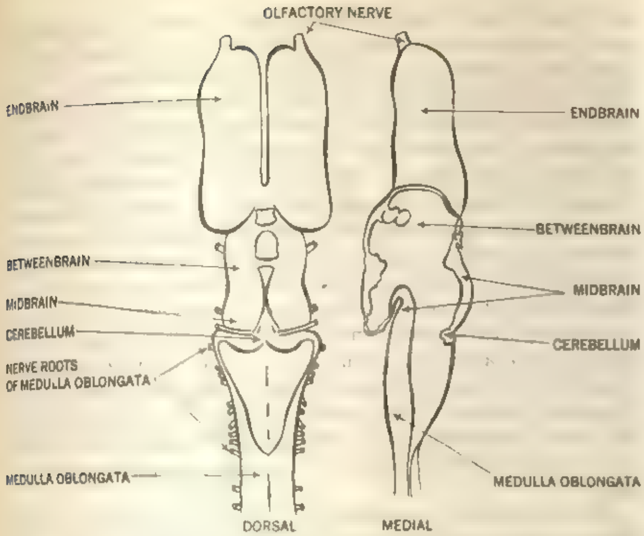
O. LARSELL

FIG. 8.—BRAIN OF YOUNG SALMON

The brain comprises five divisions (*see* below) whose relative size varies with the sensory equipment and other variables of the different groups of vertebrates. Paired nerves are attached both to the brain and the spinal cord. The spinal nerves include both sensory and motor fibres and are similar in all vertebrates but vary in number. The nerves connected with the brain are made up of diverse combinations of sensory and motor fibres and some are entirely sensory or entirely motor.

Each of the five divisions of the brain, termed the endbrain (telencephalon), betweenbrain (diencephalon), midbrain (mesencephalon), cerebellum (metencephalon) and medulla oblongata (myelencephalon), has characteristic structural patterns and functions. Part of the endbrain and all of the betweenbrain, midbrain and medulla oblongata constitute the basis of the entire organ; collectively these subdivisions are termed the brain stem (*see* BRAIN).

Lower Vertebrates.—In all but the lowest vertebrates a covering layer, the mantle or pallium, is superposed on the deep part of the endbrain, and a cerebellum is found above the anterior part of the medulla oblongata. From the pallium the cerebral cortex

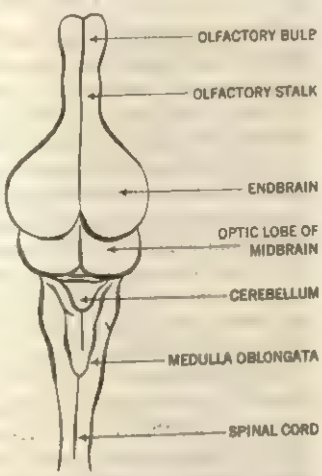


ADAPTED FROM O. LARSELL IN H. MORRIS, "MORRIS' HUMAN ANATOMY," 11TH EDITION, BLAKISTON DIVISION, MCGRAW-HILL BOOK COMPANY

FIG. 9.—BRAIN OF SALAMANDER

is differentiated. This is lacking in fishes and lower urodeles but beginning with the frog and upward through the animal series it assumes increasing size and importance; in man it is so extensive as to hide the remainder of the brain when viewed from above. The cortex consists entirely of internuncial neurons and constitutes the adjustor apparatus, which is at the same time the most complex and also of the highest order in the nervous system. The brain stem consists of complex reflex centres and their connecting fibre bundles, many of the centres having connections with the cerebral cortex as well as with the lower centres.

Mammals, Including Man.—The cortex of mammals is divided into sensory, motor and association areas. The sensory areas receive relayed impulses, such as visual and auditory, from centres in a subdivision of the betweenbrain called the thalamus. The motor areas give rise to fibres that reach lower centres related to motor activity. The association areas are small in lower mammals, but in man they constitute the greater part of the cortex. In these areas more complex patterns of integration are formed from impulses supplied by other centres, cortical and thalamic.

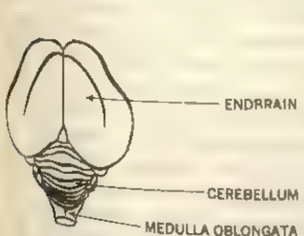


ADAPTED FROM A. FREDERIKSE, "THE LIZARD'S BRAIN," NIJKERK, NETH., 1931 (DISSERTATION, UNIVERSITY OF AMSTERDAM)

FIG. 10.—BRAIN OF LIZARD

The frontal lobe of the cerebrum, in which the most complex integrations occur, is very small in lower mammals but increases in size until in the higher apes it forms a large subdivision of the brain. In man it is especially prominent and includes the cortex involved in the highest activities of the human mind. Other lobes of the cerebral cortex also increase in size and complexity from the lower to the higher mammals.

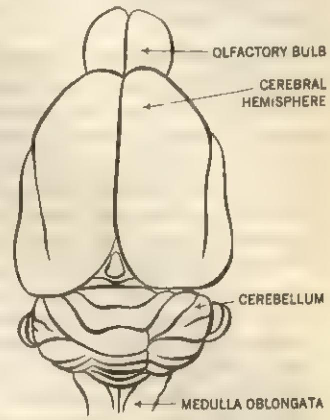
In the ascending scale, from the lowest to the highest animals and man, the nervous system becomes increasingly complex in structure. The impulses that reach it provide an increasing amount of information regarding environmental conditions, and the brain exercises an increasing dominance over the activities of lower nerve centres.



ADAPTED FROM C. J. HERRICK, "JOURNAL OF COMPARATIVE NEUROLOGY," VOL. 1, 1893

FIG. 11.—BRAIN OF GOLDEN EAGLE

In mammals as well as man the dominance over lower centres may express itself in inhibitions or modifications of behaviour that result from integrations of impulses from the most important sense organs or from memory of past experiences. Such integrations may overcome or modify responses organized at lower levels; for example, an individual with social training may suppress so purely a reflex act as a sneeze, which in the untrained person may take explosive force. Some acquired functions such as speech, recognition of spoken or written words and various skills, furthermore, are localized in one or the other hemispheres of the cerebrum. In right-handed persons the so-called dominant hemisphere is the left; in left-handed persons it is the right.



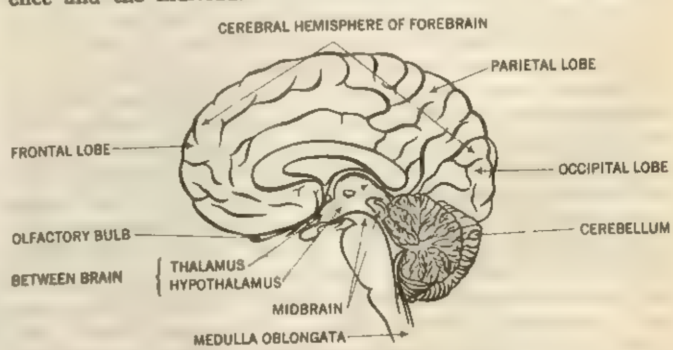
ADAPTED FROM E. HORNE CRAIGIE, "CENTRAL NERVOUS SYSTEM OF ALBINO RAT," P. BLAKISTON'S SON AND CO., PHILADELPHIA, 1925. BY COURTESY OF UNIVERSITY OF TORONTO PRESS

FIG. 12.—BRAIN OF RAT

Trends in the Nervous System.—Comparative studies of the nervous system by anatomical and physiological methods have revealed the following trends: increase in the speed of conduction of stimuli and the impulses resulting from them—for example, the rate of conduction in the nerve plexus of the jellyfish attains a maximum speed of 120 cm. (48 in.) per second, whereas in a human nerve it may be more than 100 times as fast; integration of impulses so that a given stimulus may result in increased response or in failure to respond; modification of the pattern of response; dominance by the brain as a result of connection with it of the most important sensory organs; and control of motor centres by the brain through the action of its adjustor mechanism.

The human brain is the most intricate mechanism in nature. It comprises pathways of many degrees of complexity, from a relatively simple reflex arc, illustrated by the pathway involved in constriction of the pupil in response to light (sensory impulses emanating from receptor cells in the retina of the eye travel along the optic nerve to a specific centre in the midbrain, which in turn relays these impulses to a motor centre from where new impulses are dispatched to the muscles of the iris to cause constriction), to extremely complex integrations that affect behaviour.

These latter integrations may involve not only present experience and the individual's memories of his own past, but also



O. LARSELL

FIG. 13.—MEDIAL VIEW OF HUMAN BRAIN

"racial memories" of man as stored in folklore and books. The mind, of which the brain is the organ, can analyze, synthesize and project to the future; it is capable of imagination and other qualities that give man predominance by reason of the complexity of the cerebral cortex and its connections.

NEUROPHARMACOLOGY AND PSYCHOPHARMACOLOGY are, respectively, the study of the physiological action of drugs on the nervous system and the study of the effects of drugs as seen in behaviour. The drugs of interest are said to be neurotropic; *i.e.,* they have special affinities for nerve tissue. They include anesthetics, analgesics (pain relievers), stimulants, alcohol and other depressants, barbiturates and other hypnotics, opiates and other narcotics, and tranquilizers. Most of them are discussed in detail under group titles (*e.g.,* ANESTHESIA AND ANESTHETICS; TRANQUILIZING DRUGS) or under particular drug names (*e.g.,* MARIJUANA; MORPHINE) in separate articles (*see* Index). The present article offers, first, a discussion of neurotropic drugs as a class—their history and use. The rest of the article is concerned with one subclass: the so-called psychedelic drugs, which include LSD-25, mescaline, and psilocybin. These are described in terms of their chemistry, their profound effects on the conscious state, and the social and legal issues raised by their use.

For anatomical structures mentioned in this article *see* BRAIN; NERVOUS SYSTEM. For an overview of the behavioural disorders named here *see* PSYCHOLOGY, ABNORMAL: *Abnormalities of Behaviour.*

NEUROTROPIC DRUGS

History.—Man has been experimenting for thousands of years with a variety of naturally occurring substances that act on nervous tissue: alcohol to intoxicate his weary mind, belladonna to calm an angry intestine or to poison an adversary, curare to stupefy prey from the tip of an arrow, strychnine to eliminate barnyard pests. The relief of pain, in particular, is an age-old aim of mankind, and various narcotic and sleep-producing agents were undoubtedly used by primitive man. But there is another kind of pain—the pain of being—and from time immemorial man has been trying to expand his vision, change his mood, alter his inner existence, or stupefy his awareness with such drugs as alcohol, opium, and cannabis. It is written in Genesis (9:20) that Noah planted a vineyard; "and he drank of the wine, and became drunk, and lay uncovered in his tent." Alcohol has been used by many cultures and even worshiped as a god. Opium has also been used extensively since the time of ancient Greece. Homer tells how some of Odysseus' crew succumbed to forgetfulness in the land of the Lotus-eaters. The ancient Vedic philosophers of India spoke of soma, a mysterious and probably mythical plant. Coca, coffee, and tobacco have also played their parts in history.

Several of the important early studies in physiology were directed toward understanding the site and mode of action of some of these agents; *e.g.,* the work of J. J. Wepfer in 1679 on the toxicology of water hemlock, Peter Daries' observations in 1776 of the effect of belladonna on the pupil of the eye, and the discoveries in the first part of the 19th century by two great physiologists, François Magendie and his pupil Claude Bernard, of the localization of the action of the convulsive drug strychnine to the spinal cord and of the skeletal-muscle paralyzing drug curare to the myoneural junction. These and other early studies were confined to the more accessible parts of the nervous system. Only in recent years have techniques been available for the study of chemical and electrical changes in the tissue of the brain itself—although brain responses had been inferred, from behaviour, since ancient times.

Uses.—Many of the chemical agents that affect living protoplasm are not capable of acting on the brain, but some of those that do are important in medical therapeutics (and in social relations). Examples are alcohol, the general anesthetics, the analgesic opiates, and the hypnotics, which produce sleep—all classified as central nervous system depressants. Certain other drugs, *e.g.,* strychnine, nicotine, picrotoxin, caffeine, cocaine, and amphetamine, stimulate the nervous system. These stimulants and depressants are of little if any value in psychiatric therapy. In fact, drugs truly useful in the treatment of mental illness were unknown to science until the middle of the 20th century. With the discovery of reserpine and chlorpromazine some of the major forms of mental illness, especially the schizophrenias, became amenable to chemotherapeutic treatment. Reserpine, a *Rauwolfia* alkaloid introduced in the 1940s, was soon displaced in psychiatric practice by chlorpromazine and a number of other phenothiazine derivatives, first synthesized in the 1950s. These tranquilizing drugs seem to reduce the incidence of certain kinds of behaviour, particularly hyperactivity and agitation. A second group of drugs has achieved popularity in the management of milder psychiatric conditions, particularly those in which patients manifest anxiety; this group includes meprobamate and the two benzodiazepine derivatives, chlordiazepoxide and diazepam—drugs which have a mild calming, or sedative, effect and are also useful in inducing sleep.

Not all drugs in psychiatric use have a tranquilizing action. The management of depression requires a different pharmacological effect; and the drugs of choice have been described as being euphorizing, mood-elevating, or antidepressant, depending on their particular pharmacological properties. Monoamine oxidase inhibitors such as isocarboxazid, nialamide, and tranylcypromine have been employed for this purpose, but in the 1960s the dibenzazepine derivatives such as imipramine and amitryptaline, which are closely related structurally to the phenothiazines, were more widely used. There are also drugs useful in overactive states such as epilepsy and Parkinsonism; examples are the anticonvulsant drugs diphenylhydantoin sodium and trimethadione, and the antiparkinsonian drug trihexyphenidyl. The psychedelic drugs, discussed below, also may have therapeutic uses.

THE PSYCHEDELICS

The psychopharmacological drugs that have aroused widespread interest and bitter controversy are those that produce marked aberrations of behaviour. The most important of these are *d*-lysergic acid diethylamide, commonly known as LSD-25, which originally was derived from ergot (*Claviceps purpurea*), a fungus on rye and wheat; mescaline, the active principle of the peyote cactus (*Lophophora williamsii*), which grows in the southwestern United States and Mexico; and psilocybin and psilocin, which come from Mexican mushrooms (notably *Psilocybe mexicana* and *Stropharia cubensis*). Other drugs of this group include bufotenine, originally isolated from the skin of toads; harmine, from the seed coats of a plant (*Peganum harmala*) of the Mediterranean region and the Near East; and the synthetic compounds *d*-methyltryptamine (DMT) and dimethoxyphenylethylamine. Cannabis is not usually included in this group, but there is no particular justification for its exclusion. It is a resin obtained from the leaves and tops of the hemp plant (*Cannabis sativa*), and is known by several names: bhang in India, hashish in Asia Minor and Egypt, kef in northern Africa, and marijuana in the Western Hemisphere.

Terminology.—It is difficult to find a suitable generic name for a class of drugs having as many diverse effects as have been reported for these substances. Abnormal behaviour as profound as the swings in mood, disturbances in thinking, perceptual distortions, delusions, and feelings of strangeness that sometimes occur with these drugs is usually indicative of a major mental disorder; consequently these substances are often called psychotomimetic to indicate that their effects mimic the symptoms of a naturally occurring psychosis. There are indeed points of similarity between the drug states and the natural psychoses, but there are also many dissimilarities—so many as to make the resemblance quite superficial. However, such exogenous substances as the bromides, heavy metals, belladonna alkaloids, and intoxicants can cause abnormal behaviour to a degree sometimes described as psychotic, and if the list is extended to include the drugs being discussed here, then the objection—that the term psychotomimetic should refer only to the mimicking of natural

CHEMICAL STRUCTURE OF MAJOR PSYCHEDELIC DRUGS AND CERTAIN IMPORTANT INDOLE AMINES AND CATECHOLAMINES THAT OCCUR NATURALLY WITHIN THE CENTRAL NERVOUS SYSTEM

LSD, psilocybin, and psilocin resemble structurally the brain amine serotonin in possessing the indole ring (centre). Mescaline and the two neurohumoral amines which it resembles, epinephrine and norepinephrine, are not indole compounds, but their structures can be represented to suggest a relationship to the indole ring: the carbon chain at the side, which is conventionally represented as a straight chain, can be visualized as curling around (dashed arrows) and finally forming an incomplete indole ring as drawn for mescaline, where only the bond between the final nitrogen and the carbon is missing

psychoses—is no longer valid. Taking this point of view, some investigators prefer the term psychotogenic ("psychosis-causing"). One of the most conspicuous features of this kind of drug experience is the occurrence of the distinctive change in perception called hallucination (*q.v.*). For this reason the term hallucinogenic is sometimes used. Most people are aware, however, even while under the influence of the drug, that their unusual perceptions have no basis in reality; so this is not a very accurate use of the term. Strictly speaking, very few people truly hallucinate as a result of taking a hallucinogen.

All of these terms are borrowed from medicine and are closely identified with pathology. In this sense, all are negative. Humphry Osmond proposed in 1957 that these drugs be called psychedelic ("mind-manifesting"). This term shifts the emphasis to that aspect of the drug experience that involves an increased awareness of one's surroundings and also of one's own bodily processes—in brief, an expansion of consciousness. William James observed at the turn of the century that "our normal waking consciousness, rational consciousness as we call it, is but one special type of consciousness, whilst all about it, parted from it by the filmiest of screens, there lie potential forms of consciousness entirely different" (*The Varieties of Religious Experience*, 1902). This is the experience that is sought and valued by the drug user. The term also shifts emphasis from the medical or therapeutic aspect to the educational or mystical-religious aspect of the drug experience. Only certain people, however, ever have a psychedelic experience in its fullest meaning, and the question of its value to the individual is entirely subjective. The possibility of dangerous consequences, too, may be masked by such a benign term.

None of these terms, then, is entirely satisfactory, and one or two are distinctly misleading. Since a choice must be made for convenience, the term psychedelic has been adopted here as being nonpejorative and is widely current.

History.—Native societies of the Western Hemisphere have utilized, apparently for thousands of years, plants containing psychedelic substances. The sacred mushrooms of Mexico were called "god's flesh" by the Aztecs (seemingly in close parallel with "the body of our Lord" in the Christian Eucharist). During the 19th century the Mescalero Apaches of the southwestern U.S. practised a peyote rite which was adopted by many of the Plains tribes. Peyotism (*q.v.*) eventually became fused with Christianity, and the Native American Church was formed in 1918 to protect peyotism as a form of worship. The drugs are old, and so is the controversy surrounding their use.

Scientific interest in these substances developed slowly. In the mid-19th century the psychiatrist B. A. Morel used hashish to instruct his students in the subjective nature of mental illness. The neurologist Weir Mitchell wrote about his experience with peyote before the turn of the century, and his account attracted the serious attention of two distinguished psychologists, Havelock Ellis and William James. Mescaline was finally isolated as the active principle of peyote in 1896, and its structural resemblance to the adrenal hormone epinephrine was recognized by 1919. Some interest in model psychoses (*i.e.*, drug-induced simulations of abnormal behaviour patterns) followed, but it was not until 1943, when the Swiss chemist Albert Hofmann accidentally ingested a synthetic preparation of lysergic acid diethylamide and experienced its psychedelic effects, that the search for a natural substance responsible for schizophrenia (*q.v.*) became widespread. Gordon Wasson, a New York banker and mycologist, called attention to the powers of the Mexican mushrooms in 1953, and the active principle was quickly found to be psilocybin.

Chemistry.—LSD is an amine alkaloid derived from lysergic acid, an indole compound. Both the levorotatory (*l*-form) and dextrorotatory (*d*-form) alkaloids of ergot have been isolated, but only the *l* isomers, which are derivatives of lysergic acid, are pharmacologically active. The *d* isomers are derivatives of isolysergic acid. The optical isomerism is due to the presence of an asymmetrical carbon atom in the lysergic acid portion of the molecule. LSD also has stereoisomers because of an asymmetrical side chain. The psychedelic effects of LSD occur only with the *d* isomer of lysergic acid diethylamide; the *l* isomer is inactive, as are both isomers of isolysergic acid diethylamide. Changes in the structure of the LSD molecule also alter significantly the actions of the drug. With the monoethylamide, which has one of the two ethyl groups removed from the side chain, the effects on the central nervous system are greatly reduced; and the monobrom derivative, which has a bromine atom in the 2-position of the indole portion of the nucleus, is virtually devoid of psychedelic effects.

The indole moiety in the LSD molecule is of considerable interest because of the ability of LSD to antagonize serotonin, the indole amine of natural occurrence in the brain. Several of the other drugs of this group—psilocybin, psilocin, bufotenine, harmine, and *d*-dimethyltryptamine—also have an indole moiety. It was supposed at first that this blocking property against an important brain amine might account for the psychedelic action of LSD. Subsequent study, however, with congeners of LSD indicated that the relationship is quite imperfect: methysergide and the monobrom derivative of LSD are both potent inhibitors of serotonin, yet have little psychedelic activity.

Mescaline does not have an indole moiety; it is structurally related to the adrenal hormones epinephrine and norepinephrine—catecholamines that are very active in the peripheral nervous system and are suspected of playing a role also as neurohumors (chemical mediators of nerve impulses) in the central nervous system.

Physiological Action.—The psychedelics are capable of producing a wide range of subjective and objective effects; however there is apparently no reaction which is distinctive for a particular drug. Subjects are unable to distinguish among LSD, mescaline, and psilocybin when they have no prior knowledge of the identity of the drug ingested. These drugs induce a physiological response in man that is consistent with the type of effect expected of a central-nervous-system stimulant. Usually there is constriction of the peripheral arterioles, elevation of the systolic blood pressure, dilatation of the pupils, and some facilitation of the spinal reflexes. These effects are characteristic of an excitatory response of the sympathetic nervous system and are probably mediated centrally. The brain response, as measured by the electroencephalograph (EEG), is also excitatory, presenting the familiar low voltage, rapid activity associated with states of arousal.

Experimental animals are not very susceptible to the effects of the hallucinogens; large doses generally are required to induce even a slight response. LSD in animals has effects resembling those caused by the ergot alkaloid ergonovine, which induces contractions of the uterus and is used also to relieve migraine; but LSD, unlike ergonovine, produces distinctive psychological effects at doses that have virtually no effect on the reproductive or other organ systems. It seems therefore that the psychedelics exert their principal actions on the central nervous system.

There is considerable difference in the potency of these drugs. A grown man requires about 500 mg. of mescaline or 20 mg. of psilocybin or only 0.1 mg. of LSD for full clinical effects when the substances are ingested orally. There are also differences in the time of onset and the duration. Psilocybin acts within 2 to 30 min. and the effects last about 5 to 6 hr. LSD acts within 30 to 60 min. and the effects usually last for 8 to 10 hr., although occasionally some effects may persist for several days. Mescaline requires 2 to 3 hr. for onset, but the effects last for more than 12 hr. All psychedelics presumably are lethal if taken in large enough quantities, but the effective dose is so low compared to the lethal dose that death has not been a factor in experimental studies.

Physiological tolerance for these drugs develops quite rapidly in man and monkeys: fastest for LSD, somewhat more slowly and less completely for psilocybin and mescaline. The effects are lost for a particular dose level of LSD within three days of repeated administration, but the original sensitivity is quickly regained if several days are allowed to intervene. Cross-tolerance has been demonstrated for LSD, mescaline, psilocybin, and certain of the lysergic acid derivatives. Tolerance to one of these drugs reduces the effectiveness of an equivalent dose of the second drug—which suggests a common mode of action for this group. LSD is rap

idly absorbed from the gastrointestinal tract, to become widely distributed throughout the body; it is localized particularly to the liver, but very little of it appears in the brain. It is probably excreted by the liver as 2-oxy-LSD and then eliminated in the feces. Of considerable interest is the finding that LSD disappears from the brain at about the time when the full clinical effects occur; this suggests that the action of LSD is not direct but, instead, is mediated by some alteration of biochemical events in the brain.

Attempts to localize the site of action of these drugs have been only partially successful. The reticular formation of the brainstem appears to be more sensitive to incoming sensory stimulation following LSD, and all of the psychedelics are capable of inducing an alert type of EEG pattern in the intact brain of experimental animals but not in animals having the brainstem transected just below the midbrain. This would place one site of action in the brainstem at a level above the first cervical vertebra and below the midbrain. LSD and mescaline induce paroxysmal electrical activity in rhinencephalic structures, particularly the septal region, and this activity correlates grossly with the appearance of disturbed behaviour in man and monkeys. Psychedelic agents also induce high amplitude, seizurelike wave discharges in the hippocampal structures—EEG phenomena that are associated with a disruption of learned performances in the cat. Finally, transmission in the lateral geniculate nucleus can be selectively depressed with LSD—a finding which would have a bearing on the visual effects that are so frequently reported by users of psychedelic drugs.

Psychological Effects.—Most persons regard the drug experience as being something totally removed from anything they have ever encountered in normal, everyday experience. The subjective effects vary greatly among individuals and even for a particular person from one drug session to the next. The variations seem to reflect such factors as the mood and personality of the subject, the setting in which the drug is administered, his expectation of a certain kind of experience, the meaning for the individual of the act of taking the drug, and his interpretation of the motives of the person who is administering the drug to him. Nevertheless, certain invariant reactions seem to stand out. The one most easily described by users is the effect of being "flooded" with visual experience when the eyes are closed as well as when they are open. Light is greatly intensified; colours are vivid and seem to glow; images are numerous and persistent, yielding a wide range of illusions and hallucinations; details are sharp; perception of space is enhanced; and music may evoke visual impressions, or light may give the impression of sounds. A second important aspect, which people have more difficulty in describing, involves a change in the feelings and the awareness of the self (*see* PERSONALITY: *Self-Realization and the Self-Concept*). The sense of personal identity is altered. There may be a fusion of subject and object; legs may seem to shrink or become extended, and the body to float; space may become boundless and the passage of time very slow; and the person may feel completely empty inside or he may believe that he is the universe. This type of reaction has been called depersonalization, detachment, or dissociation. Increased suspiciousness of the intentions and motives of others may also become a factor. At times the mood shifts. Descriptions of rapture, ecstasy, and an enhanced sense of beauty are readily elicited; but there can also be a "hellish" terror, gloom, and feelings of complete isolation. For some people the experience is so disturbing that psychiatric hospitalization is required. Studies of performance on standardized tests show some reduction in reasoning and memory, but the motivation of the subject probably accounts for much of the performance decrement, since many people are uncooperative in this type of structured setting while under the influence of a drug.

Medical Uses.—Interest in these drugs was routinely scientific for the first few years following the discovery of LSD, but in the 1950s professional groups began to explore the use of the psychedelics as adjuncts to psychotherapy and also for certain purposes of creativity (*q.v.*). It was at this juncture, when the drugs were employed to "change" people, that they became a centre of controversy.

LSD is not an approved drug (*see* below, *Sociolegal Aspects*); consequently its therapeutic applications can only be regarded as experimental. In the 1960s LSD was proposed as an aid in the treatment of neurosis, particularly in cases recalcitrant to the more conventional psychotherapeutic procedures, but further research was needed. LSD also was being given serious trial in the treatment of alcoholism. This type of psychiatric problem does offer an objective criterion of success: the alcoholic stops drinking. Early reports were sufficiently encouraging to warrant continued study.

LSD has also been employed to reduce the suffering of terminally ill cancer patients; here, too, preliminary results were encouraging. The drug was also under study as an adjunct in the treatment of narcotic addiction, of autistic young children, and of the so-called psychopathic personality; and the use of various psychedelics continued to be advocated in the experimental study of abnormal behaviour, because of the degree of control which they offer.

Sociolegal Aspects.—If the psychedelic drugs have social utility, it is likely to reside in their rather unusual ability to evoke a mystical-religious experience. Positive change in religious feeling is a rather common finding with these drugs. Whether they are also capable of producing religious lives is an open question. These drugs appear to enhance personal security. Out of self-trust should spring trust of others—basic trust; and this may be the psychological soil for trust in God.

The other social aspects are more debatable. Timothy Leary, a leading spokesman for LSD users, repeatedly asserted that these drugs have great educational and religious value. In June 1962 he established a Psychedelic Training Centre at Zihuantanejo, Mex., where he attempted to apply the findings and theories which he, Richard Alpert, and others had evolved while at Harvard University. The experiment was interesting but short-lived: powerful social forces were aroused (as they had been at Harvard) and the program was closed in June 1963. Various cults have since sprung up, dedicated to a mystique characterized by Leary's slogan, "Turn on, tune in, and drop out"; *i.e.*, take the drug, explore the self and universe under its influence, and renounce contemporary Western values.

LSD can be dangerous when used improperly. Mood swings, time and space distortion, "hallucinations," and impulsive behaviour are complications specially hazardous to the individual when he is alone. In the 1960s the suicide rate was not high in the various investigational groups, but the rate of serious untoward psychological effects requiring psychiatric attention climbed steadily. Technically, LSD is not addicting; however, there is a tendency on the part of those who take the psychedelics informally to repeat the drug experience and to experiment with other drugs. The special language, method of proselytizing, and psychological dependence surrounding the use of psychedelics bear striking resemblance to the context of narcotics addiction. (*See* DRUG ADDICTION.)

Cultists and scientific investigators alike, in the U.S., were handicapped after 1966 by a federal order restricting experimentation with LSD to a few laboratories; its manufacture, sale, and general use otherwise became illegal. A black market flourished, however, since the drug is readily synthesized and even a small quantity—less than an ounce—provides thousands of "trips" (individual dosages). The use of peyote (*i.e.*, mescaline) was prohibited under narcotic laws in some states and uncontrolled in others.

Psilocybin, like LSD, was limited to investigational use, with supplies under the control of the pharmaceutical company licensed to manufacture it in the U.S.

Many of the questions which these drugs pose can be answered in time by sufficient scientific research. The overriding question, however, is one which no laboratory experiment can answer, and that is the question of value. Ultimately, society as a whole must decide whether or not the psychological effects of the psychedelic drugs are desirable.

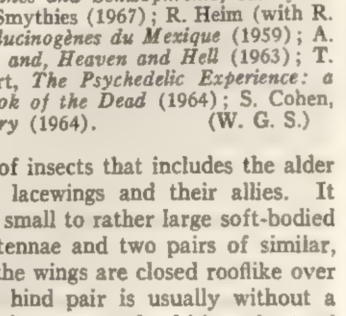
NEUROPTERA, an order of insects that includes the alder flies, snake flies, ant lion flies, lacewings and their allies. It comprises about 4,500 species of small to rather large soft-bodied insects with usually elongate antennae and two pairs of similar, net-veined, membranous wings; the wings are closed rooflike over the body when at rest and the hind pair is usually without a plicated posterior lobe. The mouth parts are for biting, the tarsi are five-segmented, and there are no cerci or tail filaments. All Neuroptera undergo complete metamorphosis, and the larvae are active and predatory with well-developed antennae, sense organs and legs; they are mostly terrestrial, but some are aquatic. The pupae have the appendages free and are generally enclosed in silken cocoons.



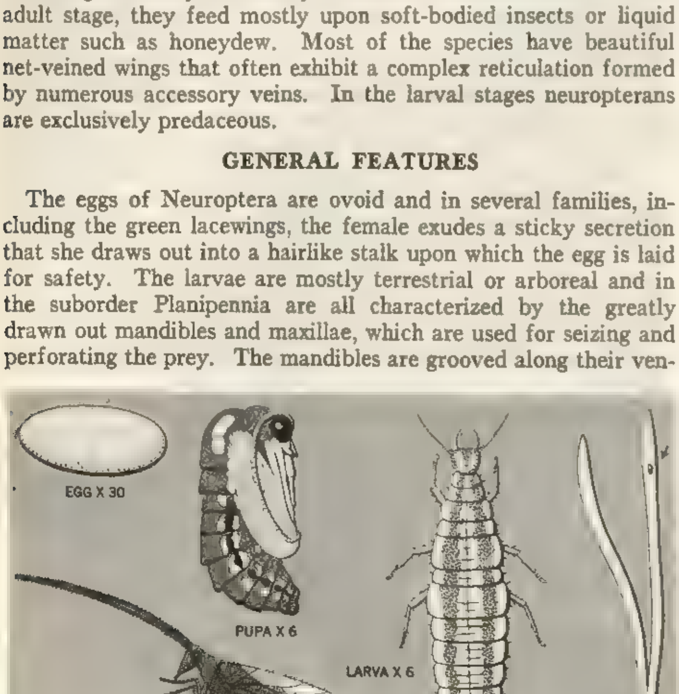
BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM (NATURAL HISTORY)

FIG. 1.—GREEN LACEWING (CHRYSOPIDAE)

Neuroptera are all insects of weak flight. They are rarely abundant as individuals. In the adult stage, they feed mostly upon soft-bodied insects or liquid matter such as honeydew. Most of the species have beautiful net-veined wings that often exhibit a complex reticulation formed by numerous accessory veins. In the larval stages neuropterans are exclusively predaceous.

GENERAL FEATURES

The eggs of Neuroptera are ovoid and in several families, including the green lacewings, the female exudes a sticky secretion that she draws out into a hairlike stalk upon which the egg is laid for safety. The larvae are mostly terrestrial or arboreal and in the suborder Planipennia are all characterized by the greatly drawn out mandibles and maxillae, which are used for seizing and perforating the prey. The mandibles are grooved along their ventral surface; the maxillae, which closely resemble the mandibles, fit one into each groove; in this way the two sets of appendages function as a pair of tubes through which the body juices of victims are sucked out. Larvae of the Planipennia are further remarkable for the fact that six of their eight excretory tubes become transformed into silk glands, the silk being emitted through an anal spinneret.



BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM (NATURAL HISTORY)

FIG. 2.—LIFE CYCLE OF THE BROWN LACEWING (HEMEROBIUS STIGMA)

Larvae of all Neuroptera are carnivorous and prey mostly upon other forms of insect life. When mature those of the Planipennia construct silken cocoons and, prior to the emergence of the adult insect, the pupa cuts open the cocoon with its mandibles and, being mobile, often travels some little distance before the imago emerges. Little is definitely known respecting the specific nature of the food of the adults; many are nocturnal in habits and are attracted to lights, while most of the day-flying species are rarely seen on the wing.

Geographical Distribution.—Certain families of Neuroptera are nearly world-wide in their distribution. Chrysopidae, for example, are found in almost all extensive areas of land except New Zealand; Sialidae have an almost world-wide though discontinuous range; while the Raphidiidae are mainly restricted to the northern hemisphere. Several families, on the other hand, are almost confined to Australia, which has a more diverse fauna of Planipennia than any other region of the globe, although the Megaloptera are represented there only by a few species. There are 13 families of Neuroptera in the United States but only 7 in the British Isles.

Geological Distribution.—Megaloptera are evidently an archaic group but their fossil remains, unless very perfect, are difficult to identify. The earliest undoubted remains of this suborder have been found in the Permian rocks of the U.S.S.R. The Planipennia first appear as fossils in Permian beds of the U.S.S.R. and Australia.

Economic Importance.—Neuroptera as a whole are distinctly beneficial to man in their larval stages. Larvae of alder flies and dobson flies form food for trout and other fishes, while those of the Planipennia prey upon many soft-bodied noxious insects. In Europe and North America the most beneficial sorts are the brown lacewings, green lacewings and the dustywings. In Australia larvae of the moth lacewings destroy numbers of chafer beetle grubs in the soil.

RELATIONSHIPS AND CLASSIFICATION

The order may be divided into two suborders, Megaloptera and Planipennia.

Suborder Megaloptera.—This suborder is characterized by veins with little or no tendency to fork at the margins of the wings, the third vein in the wing (radial sector) with few branches; larvae with biting mouth parts; and pupae not enclosed in true cocoons.

This group includes a small number of archaic insects separable into two superfamilies comprising about 200 species throughout the world.

Superfamily Sialoidea, all with aquatic larvae, include the alder flies (*q.v.*; family Sialidae), so called because in England the adults often frequent alders along the banks of streams. Their larvae respire by means of seven or eight pairs of slender, jointed, abdominal gills. The genus *Sialis* is widely distributed with many North American species and two British. Also included are the large dobson flies (*q.v.*), belonging to the family Corydalidae and found in North and South America and in parts of the old world. Smaller members of the same family are often known in America as fish flies (*q.v.*).

Superfamily Raphidiodea or snake flies are distinguished by the elongate prothorax and by the very long ovipositor in the female. They are terrestrial insects whose larvae are found under the bark of trees and feed on scale insects and aphids.

Suborder Planipennia.—This suborder is characterized by veins with evident forking at the margins of the wings, third vein (radial sector) usually with numerous branches; larvae with piercing mouth parts; and pupae enclosed in cocoons.

Included here are most of the Neuroptera. They are nearly all terrestrial insects, only a small number being partially or truly aquatic in their larval stages. Planipennia are divided into

families of which only the most important are mentioned.

Ithonidae or moth lacewings are confined to Australia; they are large, stoutly built, mothlike insects with primitive venation. Their larvae live in the soil where they prey upon those of chafer beetles, to which they bear a close general resemblance.

Hemerobiidae and Chrysopidae, the brown and the green lacewings, are widely distributed and fairly numerous in species. Their larvae roam about vegetation preying upon mites, aphids, thrips and other soft-bodied insects (*see* LACEWING FLY).

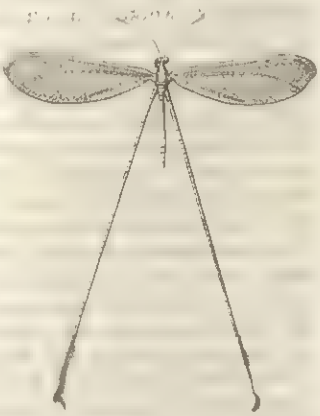
Osmylidae have aquatic larvae. They are medium- to large-sized species which differ from the lacewings in certain venational characters. They are widespread in the tropics but are represented in Europe by only one species and are absent from North America.

Sisyridae, which also have aquatic larvae, differ from the Osmylidae in having very few cross veins to the wings, besides being much smaller in size. They are brown or fuscous insects found along the borders of rivers that contain the freshwater sponge upon which their larvae feed and live. Three species of *Sisyra* occur in Great Britain, and this genus, along with *Climacia,* is found in the United States.

Mantispidae or mantis flies (*q.v.*) are easily distinguished by the elongate thorax and the prehensile forelegs, which resemble in form those of the common mantis (*q.v.*) and are likewise used for seizing other insects that serve as their prey. The larvae of the European *Mantispa styriaca* are predacious upon young *Lycosa* spiders and during development they undergo striking changes of form. The family is mainly tropical but occurs in southern Europe and in much of the United States.

Psychopsidae have very broad, rounded wings supported by a stout midrib and with a densely reticulated venation. Many are insects of striking beauty. Their larvae have been found beneath the bark of trees. The family has a wide discontinuous range occurring in South Africa, Tibet, China and Australia.

Nemopteridae differ from all other Neuroptera in having very long threadlike or ribbonlike hind wings. Their larvae occur in caves, on the floors of buildings, among debris, etc., where they prey upon smaller forms of insect life. The family occurs in many of the warmer parts of the world, including southern Europe, but is absent from North America.



BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM (NATURAL HISTORY)

FIG. 3.—NEMOPISTHA IMPERATRIX (NEMOPTERIDAE)

Myrmeliontidae or ant lion (*q.v.*) flies bear a general resemblance to dragonflies and have short knobbed antennae. Although most abundant in the warmer parts of the world, about 65 species occur in the United States, several occur in Europe, one being found as far north as Sweden, but none are found in the British Isles. Their larvae, called ant lions or doodlebugs, live on the ground, where some make pitlike snares for entrapping their prey, while others hide away under stones or debris.

Ascalaphidae are closely related to the preceding family but can be distinguished easily by their much longer antennae as well as by differences in venation. Their larvae either hide away on the ground or live concealed on the bark of trees. They are chiefly tropical insects, only a few species occurring in southern Europe and North America.

Coniopterygidae or mealywings (*q.v.*), number about 70 species and are the smallest and most aberrant of all Neuroptera. They are covered with a white powdery secretion, their wings have comparatively few veins and the hind wings are much reduced in size. Their larvae roam about plants, preying upon aphids, scale insects and mites. Many species are found in the United States but only a few species are found in Great Britain.

Tillyard, *The Insects of Australia and New Zealand* (1926).

(A. D. I.; F. M. CR.)

NEUROSES are psychological disorders which arise from a person's unsuccessful attempt to deal with inner conflicts and stressful life situations. They are adaptive in that they aim at the resolution of opposing forces within the personality through the discharge of accumulated inner tension and anxiety. The anxiety may be experienced directly or manifested in the form of bodily discomfort, phobias, obsessional thoughts, compulsive acts, mild depression, altered states of consciousness or physical complaints in the absence of organic and structural pathology. The neuroses represent attempts to obtain partial gratification for impulses and drives in a manner which was more or less successful in an earlier period of development. The disorders are benign disturbances within the personality and are to be differentiated from psychoses (*q.v.*) in that total disorganization and loss of contact with reality do not occur.

Although recognizable neurotic syndromes have been described since the Hippocratic period, the tendency for many centuries was to consider the illness a result of demonic possession or willful simulation. With the development of scientific medicine based on pathology, the 19th century considered neuroses as a primary functional disorder of the central nervous system. The French neurologist Jean Martin Charcot (*q.v.*) laid the foundations for a psychological understanding of neuroses through the use of hypnotic techniques for the treatment of hysterical disorders. The psychological approach was further developed by Sigmund Freud (*q.v.*), who demonstrated the effect of unconscious forces within the mind, the symbolic meaning of neurotic symptoms, the significant etiological agents in childhood experience, the importance of unacceptable repressed sexual and aggressive drives and a technique of treatment based on psychological principles. The modern psychiatric outlook is largely based on the discoveries of Freudian psychoanalysis.

Freud divided the neuroses into two major categories, the actual neuroses and the psychoneuroses. Although not universally accepted, this division is useful in understanding and classification. The actual neuroses include symptomatic disorders which are primarily reactions to acute stressful situations and arise as a result of excessive stimulation originating either environmentally or internally.

Symptoms are simply the discharge of accumulated tension rather than an attempt at the resolution of psychological conflict. The traumatic neuroses—such as the "shell shock" of World War I, the combat fatigue of World War II or the emotional disorders following civilian disaster—are essentially neuroses of this type. The symptoms are an attempt to deal with catastrophic external events of such magnitude that the personality has no recourse but the immediate dissipation of the accumulated tension. These reactions are short-lived and usually disappear with the removal of the stressful situation.

The actual neuroses also include reactions to endogenous stresses, that is, stimuli which arise within the organism. If a weakened personality becomes flooded by sexual or aggressive excitation, a paniclike state may result. When a state of overstimulation and insufficient motor discharge becomes chronic, diffuse symptoms such as general fatigue, tension, dizziness, insomnia, pressures and pain in the head, neck and back occur. This general state of exhaustion and bodily preoccupation is characteristic of neurasthenia and hypochondriasis.

These actual neurotic reactions may in turn become converted into psychoneurotic reactions in which the symptomatic response

carries a more elaborate psychological content. The reaction in the psychoneurotic condition is a result of the meaning of the stimulus rather than its magnitude. An objectively insignificant stress may produce a psychoneurotic reaction in a person who is particularly vulnerable because of his inability to handle such frustrations. To illustrate, in wartime a traumatic neurosis may develop following prolonged and threatening bombardment during combat. A psychoneurosis may intervene when under similar conditions the death of a comrade arouses intolerable feelings of guilt in a soldier for whom the event recapitulates a childhood jealousy of an older brother. Since Freud first distinguished the two neuroses, clinical experience has demonstrated that most actual or traumatic neuroses are frequently elaborated into psychoneuroses.

CAUSATION

Evaluation of Factors.—Modern psychiatry considers many factors in the causation of the neuroses. Although in a particular patient one factor may be more important than others, all must be evaluated in attempting to understand the origins of neuroses. Since these factors fall into a complementary series, it is unlikely that a single linear relation between specific cause and end result will be found.

Socio-Economic and Cultural Factors.—These may be causative in the development of neuroses because of the presence of conflicting and opposing values within a society. A person may strive toward the gratification of ends, such as "belongingness" and competitiveness, which are essentially contradictory. The satisfaction of one value may make it impossible to satisfy the other. A group of neo-Freudian psychiatrists have tended to relate the findings of psychoanalysis to the social sciences in order to elucidate the mutual interactions between culture and disturbances in personality. Among these, Erich Fromm and Karen Horney (*q.v.*) have considered neurotic conflict to be primarily the result of reactions to social institutions.

One type of social organization or ethnic group may encourage neurotic responses either by its own nature or by its mode of relating to a larger group. Attitudes toward class position, urbanization, sharp transitions in prevailing social codes, and prejudicial attitudes toward minority groups affect the development and content of neuroses. It is well established that social position affects to a large extent the type of treatment a neurotic patient will seek for his illness.

Constitution.—Although psychiatry does not deny the significance of heredity, this factor is not credited with the overwhelming importance attached to it prior to the 20th century. A therapeutically oriented psychiatry is inclined to minimize hereditary influences and to deal more with experiential factors subject to observation and change.

Parental Attitudes and Early Childhood Experiences.—These are considered to play a critical role in the development of faulty patterns of neurotic interaction. The experiences of the child in the family setting determine to a large extent the subsequent personality development.

An attitude of love, acceptance and security in the family tends to foster healthy behaviour patterns. Inconsistency, rejection and deprivation tend to create areas of vulnerability which may become sensitized in later life.

Oedipus Situation.—The parental attitudes and the constitutional predispositions converge at the time of the development of the Oedipus complex (*see* PSYCHOANALYSIS) to create the basic personality pattern with which the person handles situations of stress subsequently. At the ages of three to five, the child begins to develop a close, positive bond with the parent of the opposite sex and to resent and feel jealousy toward the parent of the same sex. If the previous relationships with the parents have been relatively nontraumatic, and if the parental attitudes during this stage, called by Freud the Oedipus situation, are not excessively prohibitive or stimulating, this phase of development is passed through harmoniously. Should trauma occur, regressive techniques which have been found useful in handling stress in early phases of development are again used and may become a consistent mode of handling emotional difficulties in the future. The early attempt to resolve the problems of the Oedipal situation by regression is called the infantile neurosis, and it is a forerunner of similar reactions which occur during the adult neurosis.

Following the resolution of the Oedipus complex the character structure becomes consolidated as a habitual mode of relating to situations in later life.

Precipitating Stress.—Should living provide no major frustrations, the character defenses prove adequate for adaptation and the person may then remain free of a symptomatic neurosis unless a precipitating stressful event occurs.

Interrelations.—The five causative factors are related to one another dialectically; that is, in order for a symptomatic neurosis to occur, one factor may be quite significant while another may not. Thus, socio-cultural factors may be of minimal importance but the parental influences may be markedly traumatic, or the resolution of the Oedipus complex may have left only minor psychological scarring while the precipitating event may present a major and insurmountable frustration.

Psychopathology of Neurotic Conflict.—The causative factors in neuroses were described above in a primarily chronological manner. The shifts in forces as they occur in the development of the adult neurosis can be understood as a retracing of a similar sequence.

The precipitating event is the actual life stress with which the person has difficulty in coping. It may be either a temptation or frustration, and the stress itself may penetrate consciousness only dimly. Following a period of unsuccessful attempts at adaptation through fantasy or action, a regression to earlier adaptive pattern occurs. The patterns, which resemble the infantile neurosis, were a source of gratification in early life and are thus called into play to help the person adjust to the immediate stress.

Such regressive maneuvers consume great energy, since the struggles are worked out on an unconscious level. Much effort is expended in keeping the nature of the conflict removed from awareness, because the original wishes and impulses which make up the content of the primary conflict were and continue to be highly unacceptable to the self. The apparently irrational quality of the adult neurosis thus is due to the fact that the mechanisms used to handle psychological stress, though appropriate to the unique childhood situation, are not suitable for adult life. The extent of the neurotic disability is determined by the amount of energy expended in keeping repressed and inactive the impulses which strive toward fulfillment.

The symptom itself is a symbolically expressed compromise of the conflict between unacceptable impulses and prohibitive restraints, permitting partial expression for both opposing forces.

Neurosis, Normality and Psychosis.—The distinction between normal and neurotic expression is not so great as is commonly believed. It must be realized that all persons share similar childhood experiences, and the repression of primitive impulses by the ego is a universal phenomenon in human development. Thus there is a potentiality for a neurotic reaction in most so-called normal persons, and it is likely to arise when the environment presents to the person a stress which stimulates his unique vulnerability.

In most instances, however, such neurotic reactions are not clinically significant, because they are either socially acceptable, psychologically rationalized as idiosyncrasies, or transient in appearance so that they appear as trivial occurrences such as dreams, errors or slips in speech.

The differentiation between neuroses and psychoses is more meaningful, though here too it is frequently difficult to make a rigid and meticulous distinction. For legal, social and therapeutic purposes, many psychiatrists feel a distinction is justified. In the psychoses the degree of social disorganization and loss of contact with reality is of major proportions. In contrast to the neuroses, the inner assessment of external reality in the psychoses is greatly impaired, and reality is imbued with attributes which are projections of inner experiences. The neurotic, unlike the psychotic,

does not form delusions or hallucinations, nor does he engage in forms of thinking which are bizarre and grossly illogical. The distinction is greatest in the area of social adaptiveness. The neurotic is often able to continue to function within the social unit, and others may remain unaware of the extent of his suffering.

The psychotic, on the other hand, is much more obviously a misfit, a threat to himself or to others, and markedly dissimilar in attitude and action to those around him. This does not imply that the criteria for diagnosis are social and cultural, although it is frequently stated that a particular reaction which appears in one social group as extreme deviance may be positively sanctioned and accepted in another. Though cultural relativity must be taken into account, the differentiation between neuroses and psychoses is ultimately made on the basis of the inner psychological attitudes and behaviour.

TYPES OF PSYCHONEUROTIC DISORDERS

Most classifications of neurotic disorders have been inadequate because of the multiplicity of causal factors, the general overlapping of clinical syndromes and the changing historical aspect of the neurotic illness. Whereas in the 19th century massive hysteria involving major bodily dysfunction was a common type of psychiatric illness, by the middle of the 20th century it had largely disappeared as a clinical entity, and most neurotic illness appeared to be based on disorders in character structures and personality types. Though a tendency to classify on the basis of predominant symptom complexes remained, symptomatic manifestations were found to be secondary to defects in total personality development.

In 1952 a standard nomenclature was adopted by the American Psychiatric association. Neurotic disorders and personality disorders were differentiated largely on the basis of clinical clustering rather than on the basis of etiological antecedents.

In the standard nomenclature the psychoneurotic disorders are classified as follows: (1) anxiety reaction, (2) phobic reaction, (3) dissociative reaction, (4) conversion reaction, (5) obessive-compulsive reaction and (6) depressive reaction.

Anxiety Reaction.—Anxiety is a diffuse fear which is not restricted to definite situations or objects. It is subjectively experienced as dread, apprehension or tension and may arise in any situation in which the integrity of the personality is threatened. The anxiety is not controlled by any specific psychological defense mechanism as in other neurotic reactions. Anxiety frequently arises when there is a failure of repression of forbidden sexual impulses or aggressive urges, usually in association with major life adjustments related to shifts in vocational, interpersonal, sexual or marital adaptations. The patient is in a constant or periodic state of apprehensive expectancy. Since defense mechanisms are not brought into play to handle the anxiety, it can be considered the simplest type of neurosis from a structural point of view.

The tension is frequently expressed in the form of insomnia, outbursts of irritability, agitation, palpitations of the heart and fears of death or "insanity." These patients are frequently fatigued as a result of the excessive effort they must expend in managing the distressing fear. Occasionally the anxiety is expressed in a more acute form and results in physiological concomitants such as nausea, diarrhea, urinary frequency, suffocating sensations, dilated pupils, perspiration and hyperventilation.

Phobic Reaction (Anxiety Hysteria).—A phobic reaction resembles an anxiety reaction in that the discomfort experienced by the patient is also fear. In this condition, however, the fear is of a definite external situation. The anxiety of phobic patients has become detached from a specific inner idea, object or situation and is displaced to a symbolic idea or external situation in the form of a specific neurotic fear. The patient cannot avoid experiencing acute discomfort if he is exposed to the external situation which he fears, even though he is consciously aware that no actual danger exists. The fear actually is derived from unconscious sources, such as forbidden impulses and wishes of a sexual and aggressive nature; and is displaced to an object which is symbolic of the fulfillment of the threatening wish. The commonly observed forms of phobic reactions include fear of venereal disease, fear of small enclosed places (claustrophobia), fear of high places (acrophobia) and fear of open places (agoraphobia).

The phobic patient can control his anxiety if he avoids the phobic object or situation. If he were to carry out a phobic activity it would unconsciously mean to him that he was performing the forbidden activity and gratifying the forbidden wish. The anxiety and suffering serve as a form of self-punishment for the unconscious tendencies and impulses.

Dissociative Reaction.—At times a person may handle his anxiety in such a manner as to obliterate certain functions of the personality, such as consciousness or memory. Though this is essentially a neurotic disturbance, the extent of the dissociation occasionally may reach psychotic proportions.

One of the commonest of the dissociative reactions is amnesia. Dissociative amnesia is a blotting out of awareness of highly unpleasant memories. These are experiences involving great terror, as in military combat, or experiences which have aroused great shame, guilt or loss of self-esteem.

Amnesic patients frequently accept their loss of memory indifferently and casually, indicating that a valuable protective function is performed by the reaction.

Dissociative reactions also are characterized by disturbances of consciousness such as dream states, stupor, coma and sleepwalking. Such phenomena are usually preceded by strong emotional experiences and represent the wishful reliving of an unacceptable fantasy in a dramatic and colourful manner.

In the dissociative fugue there is a temporary loss of personal identity, and actions are performed which in the patient's normal state would be firmly prohibited by the conscience. The patient may protect himself against punishment by assuming a false identity, later developing an amnesia for the experience when he returns to his usual self.

Although there appears to be a conscious deliberate element in the patient's behaviour, the dissociative reactions are actually motivated and set in action by parts of the mind that do not involve conscious volition.

Conversion Reaction.—In the conversion reactions anxiety, instead of being consciously experienced either diffusely as in the anxiety reactions or displaced as in the phobias, is "converted" into symptoms involving organs or parts of the body innervated by either the sensory or motor nerves. The symptoms serve to prevent or lessen conscious anxiety, and usually are symbolic of the underlying mental conflict. Such hysterical symptoms represent an attempt to resolve a conflict symbolically. Thus, an essentially mental content is converted into a somatic expression. To illustrate, the wish of a female patient to withhold medication from her dying father and thus hasten his death is converted into a hysterical paralysis of an arm; this partially serves to carry out the wish and also to punish the patient for entertaining the wish. The form of the conversion symptom may be determined by a somatic symptom which is contiguous to the conflictual situation. In the above example, the symptom began when the woman's arm fell asleep while she watched over her father in his illness.

Persons with a hysterical type of personality are prone to self-display and dramatic behaviour. Many are adept at ruling others directly by bids for sympathy or attention or indirectly by frightening others or by appearing pitiful and appealing. Egocentricity, predilection for fantasy and daydreaming, emotional liability and suggestibility are predominant character traits.

The physical symptoms may be either sensory or motor. Among common sensory symptoms are pain, anesthesia, numbness and such disturbances of the special senses as blindness or deafness. The symptoms are found to have a specific symbolic relation to psychologic conflict, and they differ from organic disturbances by revealing absence of neurological findings upon physical examination. The motor disturbances—common among them paralyses, tics, tremors, inability to speak (aphonia) and writer's cramp—also occur without demonstrable physiological or anatomical change.

The patient with a hysterical conversion reaction may utilize the symptom to provide himself with secondary gratifications. The secondary gain is the material, emotional and social advantage

contributed by the symptom. The presence of the symptom permits a self-justifiable escape from anxiety-provoking life situations. The symptom also provides dependent satisfactions of a regressive nature as a result of the sympathy with which the sick are frequently treated.

The successful conversion reaction, like the dissociative reaction, is accompanied by a marked absence of anxiety or conscious concern. Though the disability may mobilize concern in others, the patient may appear tranquil and content. *See* also HYSTERIA.

Obsessive-Compulsive Reaction.—In this reaction the anxiety is associated with the presence in consciousness of unpleasant and morbid thoughts or repetitive impulses to perform apparently meaningless and ritualistic acts. Although the patient may regard his ideas and behaviour as unreasonable, he is unable to control them. Either the obsessive thought or the compulsive ceremonial may arise singly or both may appear in sequence. The patient regularly repudiates the distressing thoughts, which are often highly repugnant and concerned with violently aggressive or sexually perverse impulses. However, the more he struggles to dispel his thoughts, the more insistently do they intrude. Great fear may be associated with such ruminations, and a ritualistic act frequently serves as an attempt at mastery of the fear. Although patients may fear that they are likely to act out the disturbing impulses, an obsessively neurotic patient almost never carries out the thought against which his conscience rebels so strongly.

Occasionally the preoccupations may be with absurd trivialities or circular speculations on abstruse religious or philosophical issues.

The personality of obsessive-compulsive patients is characterized by inflexibility, constant doubt, vacillation and adherence to excessive standards of morality. They tend to be overconscientious and inhibited in the expression of pleasure and in the capacity for relaxation. A tendency toward checking and rechecking of the simplest acts contributes toward lack of productivity and the consumption of much energy in unprofitable and wasteful labour.

The recurrent thought may be the direct expression of a primitive impulse or it may represent a substitute or concealment for it. A further attempt to handle the guilt and anxiety associated with the impulse is provided by the compulsive act. Should the act be obstructed in some manner, the patient will experience anxiety directly. Although most compulsive rituals are rather simple—such as persistent handwashing, counting, touching or the repetition of stereotyped words or phrases—occasionally elaborately formalized and time-consuming ceremonials are necessitated. The compulsive acts are similar to the magical expiatory rituals of nonliterate societies and similarly attempt to deal with potentially threatening situations.

The predominant psychological mechanisms utilized by the compulsive patient are undoing and isolation. The compulsive act is an attempt at undoing, since the action essentially nullifies any harm the patient feels he may cause by his wishes. The mechanism has originated in early childhood and is related to the child's propensity for utilizing magical fantasies and superstitions to master disorganizing traumatic states within the developing ego. Isolation is observed in the separation of the obsessive wish from any emotional content aside from anxiety. The wish is reacted to as if it were alien to the total personality.

Depressive Reaction.—A psychotic depression is a major disturbance involving the entire personality and disrupting contact between the patient's self and external reality. The neurotic depressive reaction is a less malignant condition, which may be precipitated by the loss of a valued person, object or idea. The emotional state is characterized by melancholy, brooding, hopelessness and an attitude of self-criticism and self-depreciation. Psychological processes, such as thought, and physical activity are retarded. There is a lack of initiative, curtailed concentration and preoccupation with feelings of guilt for past failures which are exaggerated beyond their just proportions.

Commonly, the depressive reaction follows the loss through abandonment or death of someone to whom the patient was closely attached, and in this regard it resembles a normal reaction of grief; the difference resides in the prolongation and severity of the depressive reaction and the appearance of guilt and self-accusations. A neurotic reaction results when the lost or abandoned person is regarded ambivalently, that is, when intense feelings of both love and hate are experienced toward the other person, and the hatred is felt to be unacceptable and thus repressed. In depression, since guilt prevents the outward expression of rage, the hatred is turned on the self, accounting for the feelings of unworthiness and occasional thoughts of self-destruction.

Depressive feelings may arise in situations of helplessness, frustration and great loss of self-esteem. In persons who are habitually inhibited in the expression of aggressive impulses, a depressive reaction may intervene if an external situation mobilizes the expression of such forbidden impulses. In contrast to the compulsive person, who handles his guilt by rituals of expiation, the melancholic attempts to handle his guilt by turning his hostility against his own person. The more malignant symptoms which accompany psychotic depressions, such as suicide attempts, profound stupor and physical debility, are absent.

Character Neuroses.—A large group of personality disturbances in which the defect is expressed primarily in the character rather than in symptoms are described as character neuroses or neurotic characters. The patient may not suffer from any of the usual psychological symptoms such as anxiety, depression, obsessions or compulsions, but instead may manifest generalized pathological patterns of action or behaviour.

The inner psychological problems are expressed in interaction with the environment rather than in symptom formation.

TREATMENT

The treatment of the neuroses takes two main forms: it is directed either toward the alleviation of environmental pressures or toward effecting changes within the person which allow him to cope with his external and internal conflicts more suitably.

In the acute traumatic neuroses environmental manipulation is the most desirable treatment. Temporary removal from the scene of battle during combat is effective for many in whom the neurosis was primarily a reaction to a stress of overwhelming magnitude.

Treatment directed toward the individual may be either somatic or psychological. Somatic treatment is essentially symptomatic in that no attempt is made to eradicate the roots of the psychoneurotic condition. Therapy is directed toward ameliorating the discomfort associated with the symptoms through the use of sedation, postural relaxation or pharmacological tranquilizing agents. The symptoms frequently recur when somatic treatment stops.

Psychotherapy is an attempt to deal with the patient through psychological means either through the use of reassurance and suggestion or through the provision of insight and understanding of the conflicts. In both forms of psychotherapy the essential vehicle is the communicative potential of the doctor-patient relationship. Psychoanalysis is the most thorough form of insight psychotherapy, and various modifications of psychoanalytic techniques and principles are commonly used in the treatment of the neuroses.

NEUROSES, EXPERIMENTAL are complex behavioural disturbances in animals, primarily emotional in character, produced experimentally by behavioural methods as opposed to direct assault on the nervous system by drugs, poisons, brain lesions or other physical or chemical agents.

Historical Background.—The first experimental neuroses were discovered by accident. During the normal course of his research on conditioned salivation reflexes in dogs, Ivan Petrovich Pavlov and his co-workers occasionally noted that the general behaviour of an experimental subject might change radically. A

previously manageable and co-operative dog would become unmanageable and unco-operative. Changes in behaviour were dramatic and included frequent vocalizations, restlessness or inactivity, avoidance of the experimental situation and everything associated with it, insomnia or somnolence and loss of appetite. Also noted were physiological symptoms including changes in heart rate, breathing rate and changes in the frequency of micturition and defecation; the nature of the symptom varied with the individual dog.

The following description of the onset of an experimental neurosis illustrates the profound changes in behaviour that typically occurred. In the experiment reported, the dog was being trained to salivate when a luminous circle was projected onto a screen (directly in front of the animal) and not to salivate when an ellipse was shown. This training was accomplished by giving the dog a small quantity of food whenever the circle appeared but withholding the food whenever the ellipse was presented. Eventually, the animal learned to salivate when the circle was presented and not to salivate when the ellipse was shown. After this differentiation had been established, the shape of the ellipse was approximated by stages to that of the circle by changing the ratios of the semiaxes until the ratio 9:8 was reached. At this point the differences between the circle and ellipse were so minimal that the ability of the animal to tell the difference between them practically disappeared; *i.e.*, the animal's discriminating ability became severely taxed. The animal's behaviour soon changed drastically. Pavlov wrote:

> After three weeks of work upon this differentiation [*i.e.*, ellipse 9:8 versus circle] not only did the discrimination fail to improve, but it became considerably worse, and finally disappeared altogether. At the same time the behavior of the animal underwent an abrupt change. The hitherto quiet dog began to squeal in its stand, kept wriggling about, tore off with its teeth the apparatus for mechanical stimulation of the skin, and bit through the tubes connecting the animal's room with the observer, a behavior which never happened before. On being taken into the experimental room the dog now barked violently, which was also contrary to its usual custom; in short it presented all the symptoms of a condition of acute neurosis. On testing the cruder differentiations they also were found to be destroyed, even the one with the ratio of the semi-axes 2:1. (*Conditioned Reflexes*, p. 291, Oxford University Press, London, 1927.)

In addition to difficult discriminations Pavlov found that sudden changes in the experimental procedure or the use of painful stimuli might also cause similar behavioural disturbances.

Pavlov's choice of the term neurosis was unfortunate. As pointed out by H. S. Liddell, F. A. Beach and others, the term implies that behavioural disturbances in other animals are analogous to behavioural or psychic disorders in man. Although a few investigators believe that such is the case, most are unwilling to make such an assumption. The consensus is that much more compelling evidence is needed to establish the hypothesis that human neuroses are fundamentally the same as those of other animals; a position that such is the case is more an act of faith than anything else. In human beings, the distinctive character of neurotic symptoms is related to a relatively high level of ability to think, introspect and imagine. Nevertheless, most investigators note that the types of stress that tend to induce abnormal behaviour in other animals, and the types of therapy that tend to be beneficial for them, often show instructive resemblances to stimuli that induce corresponding changes in people.

Pavlov's subsequent descriptions of behavioural disorders in other dogs, together with an enumeration of some of the variables that affected such responses, established the first meaning of the term experimental neurosis—its historical or classical meaning. For Pavlov, an experimental neurosis was said to exist when previously learned conditioned reactions were disrupted and the animal became more or less useless as an experimental subject unless given a vacation or unless other steps were taken (*e.g.*, injections of bromide had a beneficial effect on some dogs).

Once a neurosis had occurred the animal's disturbances were not confined to the laboratory but might also be observed in his pen and in his relations with humans or with other animals. Also, once established, a neurosis might last a week, a month or even years in the absence of remedial treatment.

Pavlov identified two types of neuroses, inhibitory and excitatory, distinguished from each other in terms of the performance of the animal in the conditioning situation. A failure to respond to the conditioned stimulus altogether (as in the case reported above) identified an inhibitory neurosis. Conversely, a tendency to respond to any change in the environment—that is, to respond at the slightest provocation—identified an excitatory neurosis. Pavlov found that some dogs tended to exhibit inhibitory reactions, while others developed excitatory neuroses. Such findings led him to develop a nervous system typology to which dogs were assigned depending on their symptoms.

Since Pavlov's classic studies, the meaning of the term experimental neurosis has changed greatly. It has been applied, both as a descriptive and as an explanatory concept, to widely divergent forms of behaviour (possibly sharing some common elements, however) observed in a great many species (*e.g.*, sound-induced convulsive seizures in rats and aggressive resistiveness in the pig). Such an extension in meaning has been an almost inevitable consequence of the great world-wide interest in behavioural disturbances that followed Pavlov's pioneering studies, and the hundreds of research studies that resulted. Because of this extension in meaning, however, the term has acquired an omnibus character, and the establishment of defining criteria acceptable to most workers in this area has not been possible. Accordingly, the term experimental neurosis has tended to fall into disuse in favour of purely behavioural descriptions of less complex experimentally produced changes in emotional (and other forms of) behaviour.

In effect, researchers have tended to analyze experimental neuroses into simpler, more conceptually manageable component parts, and to study these parts intensively in the laboratory. Experimental techniques uniquely suited for producing select symptoms at will have been developed, and factors influencing rather limited but well-defined behavioural disorders continue to be investigated in a variety of disciplines. Studies of conditioned emotional responses of the fear or anxiety variety, conditioned avoidance responses, conditioned reactions to punishment, conditioned conflict behaviour, conditioned physiological reactions and studies of body damage resulting from psychophysiological stress have largely replaced the broader study of experimental neurosis.

Nevertheless, as pointed out by R. W. Russell and Liddell, the term experimental neurosis is important because of its historical significance and because later observations of experimentally produced behavioural abnormalities in animals may be referred to the systematic writings of Pavlov on this subject. Also, a number of investigators have continued Pavlov's classical methods for studying experimental neuroses in animals.

Extensions of Pavlov's Work.—W. H. Gantt, at the Johns Hopkins university, and Liddell, at Cornell university, continued and extended Pavlov's work in the United States. They and their co-workers, after about 1930, worked to verify Pavlov's findings and to investigate further the variables that influence classically defined experimental neuroses and associated conditioning phenomena in a variety of mammals.

Gantt thoroughly investigated the visceral and autonomic conditioned reactions (primarily heart rate, respiration, sexual functions) that accompany motor or salivary conditioned responses in dogs. He studied these reactions—their onset, course and duration—for periods ranging from 5 to 14 years in dogs. One important finding was that heart rate is a much more sensitive indicator of conditioning effects than overt emotional reactions or conditioned motor or secretory responses. Not only were conditioned increases in heart rate established sooner, but also they continued to occur in many subjects long after overt emotional, salivary or motor components had been extinguished (in one case, even after an 18-month vacation from the experimental regimen).

Another important finding was that neurotic symptoms not previously observed might occur several years after the original behavioural trauma. Gantt reported spontaneous sexual erections in a dog, for example, both in the sound-proof enclosure in which the dog was placed for conditioning or observation and at the country retreat where the animals were taken for periods of rest and vacation. This symptom (as well as very frequent urination)

became most pronounced about two years after the main experimentation had been completed, and frequently appeared whenever an event reminiscent of the early conditioning procedure occurred (*e.g.*, the appearance of Gantt at the country retreat).

Liddell extended Pavlovian conditioning methods to other mammals. He and his co-workers studied experimental neuroses in the goat, sheep, rabbit and pig as well as in the dog, but the sheep was his standard experimental subject. After preliminary attempts to establish conditioned salivation in sheep and goats, he abandoned this procedure in favour of the defensive leg-flexion conditioned reflex.

In this procedure a signal, usually a sound or light, is turned on for a few seconds before the onset of a momentary mild shock to a foreleg of the animal. The signal and shock are terminated together. Eventually, leg-flexion, which initially occurs only at the moment that the shock is given, begins to occur at the moment the signal is turned on. At this point the animal is said to have acquired a conditioned leg-flexion reflex.

Liddell has emphasized the mildness of the shock, which, he indicates, is barely perceptible to the human hand. Although the animal starts slightly when the shock is delivered, it soon quiets down. Using this procedure Liddell has produced marked behavioural deviations in his subjects. The animals develop highly stereotyped responses which vary widely from somnolence and immobility to hypersensitivity and overactivity, both in and out of the experimental situation. Such sheep will occasionally lose their gregarious tendencies and stray away from the main flock. In at least one case this tendency caused the death of an animal, which, separated from the main flock, fell victim to maurading dogs.

The relative nonsignificance of the level of shock used by Liddell is illustrated by control experiments in which sheep were subjected to the same procedures known to produce abnormal behaviour in this species, with the difference that the conditioned stimulus or signal was omitted. Under these conditions the sheep did not become neurotic. That is, if the sheep were spared from having to listen to or see the conditioned stimulus (sound or light) they did not become behaviourally disturbed by the shock, even after hundreds of trials.

This does not mean that the animal would not eventually become neurotic, however, if shocks were given indefinitely. More than anything else, Liddell's findings demonstrate that very specific conditioned stimuli (*e.g.*, a tone) result more readily in neuroses when paired with mild shock than do very diffuse conditioned stimuli (*e.g.*, features of the experimental room, the time of day, persons present during conditioning). If a neurosis were established to such a diffuse conditioned stimulus, however, it undoubtedly would be much more pervasive and much more difficult to remedy. This expectation is in line with other research which has shown that emotional behaviour conditioned to a diffuse, ambiguous stimulus situation lasts longer and is harder to eradicate than are behavioural disorders conditioned to a clearly defined conditioned stimulus.

Liddell emphasized the temporal relations between the various phases of the conditioning procedure in the production of experimental neuroses. Two types of reproducible abnormal responses that are dependent upon the duration of the interval between trials have been observed in sheep and goats. The first is a forced extensor rigidity of the foreleg to which the shock electrodes are taped; this symptom occurs when a regimen of ten conditioning trials each day, separated by two minutes each, is employed. The second type is an increase in the number of leg flexions, beginning with the onset of the conditioned stimulus and continuing until the shock is delivered; this symptom is seen when the same number of daily trials is given (*i.e.*, ten) but the interval between trials is extended to seven minutes. The first case was likened by Liddell to Pavlov's inhibitory neurosis, the latter to Pavlov's excitatory neurosis.

Other Approaches.—N. R. F. Maier, B. W. Lichtenstein and J. H. Masserman among others, produced atypical responses in rats, cats, dogs and monkeys using conditioning methods other than those of Pavlov.

Maier trained rats to jump across a space to one of two distinctive stimulus cards in order to receive a food reward. If the animal jumped to the correct card, the card fell over and the animal landed on a platform where a piece of food was found. A jump to the incorrect card resulted in a bump on the nose (the incorrect card was locked in place) and a fall into a net below. The correct card was changed from right to left, at random, to prevent the animal from learning to jump always to one side.

The animals readily learned to jump to the correct card. Then the procedure was changed so that the previously correct card was locked in place during 50% of the trials, randomly determined. With this change in procedure a jump to the card previously designated correct resulted in a bump to the nose and a fall into the net on half the trials. After a few trials with the changed procedure, the animals showed great hesitancy before jumping, and eventually stopped jumping altogether.

Maier then forced the animals to jump by directing a jet of air at them, or by applying an electric current to the stand. Under these conditions the animals soon developed abnormal jumping responses, punctuated by stereotypy, and some animals showed violent running fits (after leaping to the floor instead of jumping to a card), or convulsive seizures.

Maier argued that the seizures of his rats were caused by the conflict engendered in them when forced to make a choice in the unsolvable choice situation. Although conflict may play a role, C. T. Morgan, F. W. Finger and J. Wolpe are unconvinced of the necessity of a conflict formulation. Morgan, for example, produced similar convulsions in rats by exposing them to the sound frequencies produced by a hissing air stream, in the absence of any conflict.

Lichtenstein and Masserman produced feeding inhibitions in dogs, cats and monkeys. The procedure involves shocking or blowing a stream of air at the animal or exposing it to a so-called psychologically traumatic stimulus at the moment food is taken. A psychologically traumatic stimulus is a fear-arousing but physically innocuous stimulus. Monkeys, for example, seem afraid of toy snakes. When a feeding inhibition is established, the animal refuses to eat in the experimental situation, even though he should be intensely hungry. The animal may also refuse food in its home cage.

The most striking result of Lichtenstein's experiments was the alleviation of the learned feeding inhibition in dogs by prefrontal lobotomy. The inhibition was reconditioned after the operation and alleviated again by a second posterior cut. Finally, the response was again conditioned and alleviated once more after a third sectioning of the forebrain.

Masserman emphasized the role of motivational conflicts, or conflicts among basic needs of the animal, as causative factors in the development of experimental neuroses. His dynamic formulations reflect his psychoanalytic orientation and are couched in terms to make them applicable to human as well as to animal behaviour disorders. The need for a conflict formulation, however, is not established. Wolpe showed that the same sort of behavioural disorders reported by Masserman may be produced by shocking cats or directing air at them, even though these disagreeable events are never associated with eating or food getting. Perhaps the most instructive outcome of Masserman's work is his determination of therapeutic procedures which appear to have beneficial effects in people and other animals. This, of course, should not be taken as prima facie evidence that the dynamics underlying the observed changes in behaviour are identical.

Theories About Causes.—Many theories attempt to explain experimental neurosis. Perhaps the most frequently quoted are those of Pavlov, Gantt and Liddell.

Pavlov believed that behavioural disturbances in both man and animal are caused by a conflict between cortical processes of excitation and inhibition which, under normal conditions, are kept in balance. His theory can be understood best perhaps, in the terms of a conditioning experiment.

In the circle-ellipse experiment noted above the cells of the salivary gland presumably were stimulated (ultimately) by cortical brain cells whenever the circle was presented; this stimulation de-

fined a cortical excitatory process. Secretion of saliva presumably was inhibited whenever the ellipse was presented; this defined a cortical inhibitory process. When the stimulation entering the central nervous system from the circle and the ellipse became so similar that both excitatory and inhibitory processes tended to be aroused simultaneously (*e.g.*, when the semiaxes of the ellipse were in the ratio of 9:8), the pronounced conflict between these processes became too much for the animal's nervous system, and experimental neurosis resulted.

Cortical conflicts might occur also, Pavlov believed, if either excitatory or inhibitory processes became overstrained. Excitatory overstraining might occur if conditioned stimuli of greater intensity than normal were introduced during a conditioning experiment; inhibitory overstraining, if the animal were forced to wait longer than usual for a reinforcement—*e.g.*, food during salivation experiments. (A reinforcement is an object or event that elicits an unlearned response or reflex; *see* ANIMAL BEHAVIOUR.)

Gantt enunciated two principles that he considers fundamental for understanding the causes of experimental neurosis—principles evolved from his intensive, long-term study of individual dogs. The first he terms schizokinesis and the second autokinesis.

Schizokinesis refers essentially to the animal's propensity to overreact, autonomically, during the process of acquiring adjustive reactions (*e.g.*, conditioned responses). Thus, Gantt considers as pathological the persistence of conditioned heart-rate responses long after overt conditioned reactions have disappeared. He suggests that other autonomic effects associated with conditioning (such as increased stomach acidity and the release of adrenalin by the adrenal medulla) may disturb the normal functioning of the organism and pave the way for later behavioural pathology.

The term autokinesis refers to another organismic propensity which further contributes to the formation of behavioural disorders. This is the tendency for earlier traces of long-past incidents to undergo dynamic change in the nervous system (to ferment, as it were) and eventually make their presence known as new symptoms which may appear years after the original disturbance. Unlike schizokinesis, however, autokinesis may also work in favour of the organism. Gantt suggests that autokinesis may be responsible for long-term effects of therapeutic efforts which may not be visible in the short run.

Liddell's theory emphasizes the strains and stresses of the conditioning situation itself as instrumental in causing experimental neurosis. He was greatly impressed by the resistance of his animals to Pavlovian conditioning. He sees the whole conditioning procedure as stressful, constantly taxing the nervous system of the animal, forcing it to maintain a state of readiness or vigilance. This state has been compared to what H. Selye termed the alarm reaction, the first stage of the organism's physiological response to stress. The restriction imposed on the animal by the chamber and restraining harness used during conditioning, and the animal's self-imposed restriction in attending and responding to the monotonous and regular conditioned signals, inevitably followed by relatively inconsequential amounts of shock or food, are the sources of its neurosis, according to Liddell. He suggests that the conditioned signal triggers innate, tense, preparatory reactions in the animal (*i.e.*, vigilance) which, in the animal's natural environment, prepares it for fight or flight. Moreover, the effects of repeatedly triggering the vigilance reaction (day after day and month after month) generally tend to be cumulative.

Gantt's and Liddell's theories point up the reality and primacy of autonomic conditioning, and the effects of monotonous provocations, respectively, in the development of abnormal animal behaviour. The degree to which these findings may be generalized to man, however, remains an open question, which further research should settle.

Many other theories have been proposed to explain experimental neuroses, both as classically defined by Pavlov and as defined by some of the later workers. Notwithstanding the extant theories, most workers in the area of emotional behaviour agree that a better understanding of the more elemental emotional reactions of animals (*e.g.*, conditioned "fear," conditioned avoidance behaviour, conditioned punishment reactions) must precede a better understanding of a phenomenon as complex as experimental neurosis, however defined. An adequate theory should also assign due weight to genetic constitutional factors, innate behavioural tendencies, and to the tendency to misconnect causes and events (*i.e.*, to learn "superstitions"). Happily, the investigation of such simpler emotional reactions and the role played by genetic and other variables in disturbed emotional behaviour is being vigorously pursued in many laboratories.

NEUSIEDLER LAKE (NEUSIEDLERSEE; Hungarian FERTŐ), situated in Burgenland (east Austria) and northwest Hungary, is slightly saline, very shallow (2–10 ft. deep), and its level and size (about 125 sq.mi.) vary with climatic fluctuations. In 1742, 1811, 1865 and 1871 it almost completely disappeared. Its origin is not completely established, but it was formed during the Pleistocene probably as the result of tectonic subsidence which brought its present bed below groundwater level. Neolithic and Bronze Age finds do not indicate *Pfahlbauten* (pile dwellings) but a smaller size lake in prehistoric times. A canal (dug 1873–95) links its southern part with the Répce, a Danube tributary, and drains or adds water according to the seasons. A protected area since 1935, the heavy growth of reeds around its banks constitutes a noted bird sanctuary sheltering about 250 species. The lake has a beneficial influence on agriculture as a regulator of climate and ground water, and its reed resources, at present inadequately utilized, provide raw materials for cellulose manufacture and various building materials. The lake is fished, mainly for carp, and serves as a recreation area for nearby Vienna. Major places on its shores are Neusiedl, Podersdorf (the main summer resort) and the wine centre of Rust. (K. A. S.)

NEUSS, a town of Germany in the *Land* (state) of North Rhine-Westphalia which after partition of the nation following World War II became part of the Federal Republic of Germany. It is an important traffic centre at the junction of railway lines to Cologne, Viersen, Zevenaar (the Netherlands), Düren and Rheydt. Neuss lies near the west bank of the Rhine, opposite Düsseldorf, with which it is connected by the Erft canal, and its harbour makes it accessible to small ocean-going vessels. Its population (92,916 in 1961) is predominantly Catholic. Neuss was founded as a Roman fortress (the Novaesium of Tacitus); it was later captured by the Franks and was renamed Niusa. The town, which was chartered 1187–90, was unsuccessfully besieged by Charles the Bold (1474–75); it was sacked by Alessandro Farnese in 1586 and passed to Prussia in 1816. Now an important industrial centre its various enterprises include the manufacture of machinery, screws, rivets, chemicals, concrete, rope, ceramics and bricks. Neuss is also an important grain market and food-processing centre.

The Quirinus church (damaged during World War II) is a fine example of the transition from the Round to the Pointed style. The Romanesque Obertor (a massive gatehouse), part of the medieval town fortifications, houses the Clemens-Sels museum, which contains Roman antiquities, medieval pictures and sculptures, numerous documents of local history and a modern section.

The "Neusser Kirmes," a famous Rhineland *Schützenfest* (rifle marksmanship contest) takes place at the end of August.

(I. F.)

NEUSTADT AN DER WEINSTRASSE (formerly NEUSTADT AN DER HAARDT), a town of Germany in the *Land* (state) of Rhineland-Palatinate which after partition of the nation following World War II became part of the Federal Republic of Germany. Pop. (1961) 31,567. It lies 22 km. (14 mi.) W. of Speyer at the junction of railway lines to Worms, Weissenburg and Kaiserslautern. Its convenient location and picturesque setting under the eastern slope of the Haardt mountains at the mouth of the Speyerbach have made it a favourite tourist resort. Neustadt is the centre of the Pfalz wine trade and the famous *Deutsche Weinlesefest* (wine festival) is held annually in October. The training and research institute of viticulture and horticulture is of international repute. The town was chartered in 1275 and its historic buildings include the Casimirianum (the seat of Heidelberg university, 1578–83, now a popular convention hall), the *Stadthaus* (formerly a Jesuit college) and the 14th-century Gothic Abbey church (Stiftskirch). Apart from the wine trade, economic activities include food processing and the manufacture of metal products, textiles, paper and concrete.

NEUSTRELITZ, a town of Germany which after partition of the nation following World War II became part of Neubrandenburg *Bezirk* (district) in the German Democratic Republic. Pop. (1961) 27,663. It is situated on the Zierker See, 107 km. (67 mi.) N. of Berlin by road. Extensive agricultural land surrounds the town, which was severely damaged in the last days of World War II. A junction on the Berlin-Stralsund railway, economic activities include foodstuffs, wood and engineering manufactures. Neustrelitz was incorporated in 1736 and until 1918 it was the residence of the grand dukes of Mecklenburg-Strelitz.

NEUSTRIA, in the Merovingian period of French history, was the western Frankish kingdom as opposed to Austrasia (*q.v.*), the eastern kingdom. The term appears in the chronicle of the pseudo-Fredegarius (mid-7th century). While Austrasia, by derivation, was the land in the east, Neustria was the "new" (Fr. *neuf;* German *neu*) land; *i.e.*, the whole area colonized by the Franks since their settlement in the north and northeast of Gaul. A similar distinction was made in the Lombard kingdom in northern Italy, where the names "Austria" (= Austrasia) and "Neustria" denoted the territory to the east and to the west, respectively, of the Adda river. In Frankish history the 7th century was marked by rivalry between Austrasia and Neustria, whose king often also ruled over Burgundy. The victory of Pepin of Herstal, mayor of the palace in Austrasia, over the Neustrians at Tertry in 687 assured the ultimate ascendancy of Austrasia.

In the later Merovingian period the names Neustria and Francia were used interchangeably by Neustrian writers to designate the kingdom of which they were subjects, thus betraying their conviction that Neustria formed the heart and core of the Frankish lands. Later the name Neustria came to denote a much smaller area, the territory between the Seine and the Loire; and when, in the middle of the 9th century, the Bretons gained control of the districts of Nantes and Rennes, the name Neustria was used to denote a still more restricted area. Indeed, in the 11th and 12th centuries certain writers used "Neustria" synonymously with "Normandy." In the same way the name "Austrasia," superseded in its former location by "Lotharingia" under the Carolingians (*see* LORRAINE), was sometimes later used to denote the land originally settled by the Hessian Franks (*Chatti*); *i.e.*, the valley of the Main river, still later called Franconia.

NEUTRALISM. In the two decades following World War II this term came to mean the policy of nonalignment with major allied systems as pursued by India, Burma, the United Arab Republic, Yugoslavia and most of the new Asian and African states. These countries refused to align themselves with the Communist bloc led by the Soviet Union or with the western bloc led by the United States, but they were not "isolationist"; as members of the United Nations they took an active interest in international problems.

A similar policy, known as the avoidance of "entangling alliances" or as "isolationism," was advocated for the United States by Presidents Washington and Jefferson and pursued during the European wars between France and Great Britain after the French Revolution, and for a century after the peace of 1815. President Wilson sought to depart from this policy after the United States entered World War I but the senate's rejection of the League of Nations and of the alliance with France and Great Britain against Germany resulted in a continuance of the neutralist policy until World War II.

After World War II the United States not only abandoned this policy itself by creating the North Atlantic Treaty organization and other alliances against Communism but also criticized other states for pursuing a neutralist policy. It was sometimes suggested in congress that economic assistance should not be given to neutralist countries but only to American allies. This attitude, however, began to change in 1956 as the power situation between the great blocs was becoming more evenly balanced, as the practical difficulties of the neutralist states became more obvious, as the Soviet Union began to give economic aid to these states and as it became apparent that unless the west continued to give them aid, the neutralist states would become wholly dependent upon the Communist bloc.

Neutralism and Neutrality.—Neutralism is often confused with neutrality (*q.v.*) but the two terms have distinct meanings. Neutralism refers to the foreign policy of a state in time of peace while neutrality is a term of international law referring to the rules that states are obliged to follow during a legal state of war in which they are not belligerents. Their neutral status implies strict impartiality and abstention from any assistance to either belligerent and the enjoyment of rights of maritime trade with all belligerents subject to the danger of belligerent capture and condemnation of neutral ships for carriage of contraband, breach of blockade or unneutral service. During the 19th century the United States not only pursued a policy of neutralism but it also carefully observed the obligations and demanded the rights of neutrality during wars between other states.

Neutralist states have justified their position not only for practical reasons but also in principle on the ground that everyone should be presumed innocent until proven guilty. In accord with this principle they have declined to assume in advance that the United States, the Soviet Union or any other country is intending to embark upon an aggressive action or other violation of the charter before an incident arises and, therefore, have refused to enter alliances or collective defense arrangements directed against particular states. They have also declined to assume that the ideology or the political or economic system with which a nation conducts its domestic affairs violates its international obligations; they assert that this attitude accords with the United Nations charter provision that forbids intervention in matters essentially within the domestic jurisdiction of any state. It would therefore seem that a policy of neutralism is entirely in accord with the obligations of UN members but neutrality in the conventional sense is forbidden if the UN functions, as it is supposed to, in determining the innocent and guilty party in hostilities. (Q. W.)

NEUTRALITY. As understood at the beginning of the 20th century, when it held an honoured place among the situations regulated by international law, neutrality could be defined as the legal position of third states which, in a war between two others or groups of others, chose to remain apart from the conflict, but in doing so had certain rights and duties that had to be respected by the belligerents and observed toward them. War was then a legal procedure over the initiation of which the unorganized community of nations exercised no control. When a state found its rights violated or its just claims denied, it might have recourse to force to vindicate them. States not directly involved in the conflict thereupon declared their neutrality and adopted a position of impartiality toward the belligerents.

Historical Background.—It was one thing for the neutral state not to take sides between the belligerent governments and quite another to be willing to abandon its trade with the citizens of the belligerent countries. Early in the 18th century, Holland

Sweden and other maritime countries felt that they should have the right to continue their normal trade relations with the countries at war, and they resisted the restrictions that the belligerents sought to impose upon them. By the time of Vattel's treatise on the law of nations in 1758 the rights of neutrals were defined along general lines, but new situations were constantly arising to create controversies. The United States had scarcely won its independence when it found in 1793 that both Great Britain and France were violating its rights as a neutral, capturing its vessels on grounds of alleged breach of blockade and carriage of contraband. The situation led to hostilities with France in 1798 and became so acute in 1812 that the United States, harried by the "paper blockades" of both belligerents, declared war against Great Britain as the worst offender. Paradoxically enough, when the United States was at war in 1861–65 it extended the scope of the existing rules of blockade and contraband (*qq.v.*), and in the famous case of the "Alabama" held Great Britain to account for allowing the construction of a Confederate cruiser in its neutral ports. (For a statement on neutrality stemming from the Crimean War *see* PARIS, DECLARATION OF.)

At the end of the Napoleonic Wars the great powers that were represented at the Congress of Vienna agreed upon the principle of the perpetual neutrality of Switzerland and thereafter Switzerland successfully maintained its neutrality. In 1839 the great powers of Europe also recognized Belgium as a perpetually neutral state and bound themselves to intervene if either party to a war violated that neutrality. During the Franco-German War of 1870–71 the neutrality of Belgium was reaffirmed by treaties concluded by France, Prussia and Great Britain.

1907: New Conditions and New Rules.—The opening of the 20th century found the conflict between belligerent and neutral interests even more acute than a century earlier. Nations still retained the right to go to war at will, but with the advance of science the instruments of war had become more destructive and the commerce of neutrals far more extensive, with resulting conflicts of interest. The second Hague conference of 1907 sought to compromise the conflicting interests, adopting two separate conventions, one dealing with the rights and duties of neutral states in war on land, the second dealing with the rights and duties of neutral states in naval war. The adoption of the first convention offered little difficulty, since the principle of the inviolability of neutral territory was already well established; but the second was complicated by questions of naval power, the size of merchant marines, colonial possessions and other factors bearing upon the success of naval warfare. The outstanding controversies were concerned with the scope of contraband and the effectiveness of blockade. The United States, anticipating the status of a neutral, sought to have the rules drafted as much as possible in favour of neutral commerce; Great Britain, anticipating involvement in a war, pressed for restrictions upon commerce in the interest of the effectiveness of naval power. Lists of contraband were drawn up, but it was difficult to determine what should be done with articles that were susceptible of use in war as well as for purposes of peace. Belligerents must not blockade neutral ports; but what if goods ostensibly destined to a neutral port were to be transshipped to a neighbouring belligerent country? Could neutral vessels be destroyed when captured for carriage of contraband or breach of blockade under circumstances when they could not be taken into a belligerent port for adjudication? These and numerous other questions were left unsettled by the convention and were taken up a year later at the London Naval conference; but the compromises there reached, embodied in the Declaration of London, had not yet been ratified when war broke out in 1914.

Breakdown of Neutrality.—Elaborate as were the provisions of the agreements adopted at The Hague in 1907 they proved unequal to the strain put upon them when war broke out in 1914. Germany's violation of the neutrality of Belgium at the opening of the war proved to be a forecast of what was to come. Great Britain pressed hard upon the neutral rights of the United States by diverting vessels for search in port, requisitioning them and extending the rules of blockade and contraband. Germany pressed even harder with submarine attacks upon passenger ships. The sinking of the "Lusitania" in 1915, followed by the renewal of submarine warfare against merchant ships in 1917, finally led the United States to declare war. Before that, however, on Oct. 16, 1916, President Wilson, harassed by both belligerents, had come to the conclusion that it was time to put an end to the right to make war. The "business of neutrality," he said, was over. No nation must henceforth be permitted to set in motion forces so destructive to the normal commerce of peaceful nations. War by its very nature put the neutral state in a position where it must either abandon its neutral rights or fight to maintain them.

Such was the intent of the covenant of the League of Nations. The members of the League undertook to act collectively to protect one another. A state that resorted to war in disregard of its pledges of pacific settlement was held to have committed an act of war against all other members of the League, which were pledged to discontinue trade and financial relations with it. Neutrality was now at an end. An individual state might still have recourse to force, but the collective action taken against it, in whatever form, would not be "war" in the old technical sense. The council of the League explicitly declared in 1920 that, "The idea of neutrality of members of the League of Nations is not compatible with the other principle that all the members of the League will have to act in common to cause their covenants to be respected."

Under these circumstances it is of interest to note that Geneva was chosen as the permanent seat of the League because of Switzerland's neutrality. The League council in 1920 recognized Switzerland's permanently neutral status and agreed that no military force would be required of it in the event of a breach of the covenant (*see* SWITZERLAND: *History*).

Neutrality Revived.—The United States, the former champion of neutral rights, refused to ratify the treaty of Versailles, which embodied the covenant of the League of Nations. What then would be its rights as a neutral in the event of collective action by the League? If it insisted upon trading with a state against which the sanctions of art. 16 of the covenant were being applied, the sanctions could not be effective. Advocates of the League argued that there was a moral obligation upon the United States to forego claiming its neutral rights under such circumstances. The moral obligation was held to have been given legal force by the provisions of the Pact of Paris of 1928 (*see* KELLOGG PACT), which condemned recourse to war and renounced it as an instrument of national policy. But the implied exception of the right of self-defense left the situation somewhat uncertain; and under the circumstances the American republics, meeting in Havana in 1928, felt it desirable to adopt a formal convention on maritime neutrality, based largely upon the Hague convention of 1907, with an exception in favour of states having obligations previously undertaken. War between Bolivia and Paraguay raised issues as to the applicability of the convention, with the result that the Argentine antiwar treaty of 1933 made provision that, in case of noncompliance by a state with the obligations of nonaggression and pacific settlement, the contracting parties would "adopt in their character as neutrals a common and solidary attitude," thus reinstating neutrality if the League of Nations should fail to act.

Neutrality on the Eve of World War II.—As the clouds of war grew darker with the attack by Japan upon China in 1931 and the attack by Italy upon Ethiopia in 1935 the debate among jurists became more acute. The leading European jurists, and many American jurists also, looked upon neutrality as fundamentally immoral because it represented a refusal to distinguish between right and wrong in the conduct of states; other American jurists found it impractical to make the distinction and advocated policies of restriction upon traditional neutral rights. The U.S. congress responded to the appeal that the country must not be drawn into a war by the commercial interests of its citizens seeking the profits of neutral trade with the belligerents, as was said to have been the case in World War I. A law of 1935 made it illegal to export arms, ammunition or implements of war from any place in the United States to any port of the belligerent states or to any neutral port for transshipment to a belligerent country; and a later section made it unlawful for American citizens to travel as

passengers on vessels of a belligerent nation (except at their own risk), thus preventing loss of American lives by another "Lusitania" disaster. A year later, in 1936, a second law made it illegal to make any loan or extend any credit to a belligerent, thus depriving bankers and munitions makers of any business interest in the outcome of the war. Again, in 1937, a "cash-and-carry" plan was put into effect; it provided that certain articles and materials, as determined by the president, were to be paid for before leaving the United States and were to be transported in the vessels of some other country. The president was to determine when a state of war existed and issue a proclamation to that effect. All three laws clearly indicated that no discrimination would be made between the possible belligerents on ground of acts of aggression in violation of the Kellogg pact.

Neutrality During World War II.—When war broke out in 1939 there was a temporary revival of the traditional law of neutrality. The League of Nations found it impossible to put into effect the provisions of the covenant under the circumstances of such a bold challenge to its authority. The smaller European powers were permitted to remain neutral for a time, but only while the Axis powers were gathering their forces.

In the western hemisphere the United States took the lead in proclaiming its neutrality, going so far as to announce that it was "on terms of friendship and amity with the contending powers," no distinction being made between them in line with the implications of the Kellogg pact. Following the lead of the United States the American republics, in accordance with decisions taken at the conferences held in 1936 and 1938, met at Panama on Sept. 23, 1939, and issued a general declaration of neutrality, setting forth certain standards they proposed to follow and creating an Inter-American Neutrality committee to formulate recommendations with respect to problems that might arise. At the same time the Declaration of Panama was issued; it proclaimed that "as a measure of continental self-protection" the American republics were entitled to have the waters adjacent to the American continents free from the commission of hostile acts by the belligerents. A "zone of security" was marked off, defining the area from which belligerent operations were to be excluded. No measures of enforcement were provided in the declaration, but the use of the term "self-protection" indicated that a violation of the declaration would not be taken lightly. Great Britain protested against this extension of neutral rights, which, it insisted, required its specific assent to become binding. In like manner the German government held that the zone of security could not be regarded as in force until accepted. Within three months of the issuance of the declaration the German battleship "Graf Spee," damaged in an engagement with three British cruisers, took refuge in the harbour of Montevideo. Having exhausted its permissible stay the vessel left the harbour and by prearrangement with a German merchant ship was scuttled at a point within the river claimed by Uruguay to be within its territorial waters.

On the continent of Europe one violation of neutrality succeeded another. On Feb. 17, 1940, a British destroyer pursued the German transport "Altmark" into Norwegian territorial waters and rescued from its decks hundreds of officers and men belonging to various British merchant ships captured and sunk by German warships. Norway protested, but two months later the country as a whole was occupied by German troops. The occupation of Denmark by Germany and that of Greece by Italy followed. On May 10, the German government, alleging that it was in possession of evidence that the Allies were about to attack through Belgium, the Netherlands and Luxembourg, invaded these three neutral states without warning. On its part Great Britain occupied Iceland in order to forestall a German invasion of the island. Yugoslavia, refusing to depart from its position of neutrality, was occupied by the Axis armies on April 6, 1941.

Endless controversies developed over the scope of contraband goods, whether absolute or conditional, and the effectiveness of blockade. Goods such as rubber, which had never been classified as contraband in earlier wars, were now found to have great value for military purposes, making the lists of the Declaration of London meaningless. The earlier doctrine of the "ultimate destination" of cargoes left the neutral free to sell its goods in the open market of a neutral state. But what if a neutral state adjacent to Germany should transship the goods to the enemy state? Would not that constitute an indirect violation of the blockaded enemy ports? Even a guarantee from the neutral state that the goods would be consumed in the country still left the neutral state a larger portion of its own domestic produce to transship to Germany. So argued Great Britain on both points. The meeting of foreign ministers of the American republics at Panama in 1939 protested the placing of foodstuffs and clothing intended for civilian populations on lists of contraband, but to no avail. New circumstances had arisen and war, said both belligerents, was not what it used to be.

The United States, as the leading neutral, yielded on most points; or rather, with the experience of World War I behind it, the dominant opinion in congress was that it was better to abandon the "freedom of the seas" than to risk a conflict in the interest of the commerce of its individual citizens. But its sympathy with the Allied powers grew stronger with each new incident. In July, 1940, a meeting of foreign ministers of the American republics was held at Havana at which, in anticipation of a possible victory of Germany, a system of regional defense was adopted, accompanied by a convention providing for the provisional administration of European colonies and possessions in the Americas, clearly indicating the realization that a victory of Germany would be a danger to the western hemisphere.

More directly contrary to its status of neutrality were the negotiations of the United States with Great Britain by which 50 destroyers, described as "out-of-date," were exchanged for the lease of naval bases on British islands in the Caribbean. The fact that Germany chose to overlook the transaction rather than risk an open break with the United States did not make the act any the less a violation of neutral duty, and the allegation of self-defense was without justification except in anticipation of a German victory.

But the exchange of destroyers for naval bases was a minor violation of neutrality compared with the passage of the Lend-Lease act on March 11, 1941, by which congress authorized the president to lease, lend or otherwise dispose of defense articles to the government of any country whose defense the president deemed vital to the defense of the United States. This act was justified on the ground that Germany had violated the Kellogg pact, thus permitting other parties such as the United States to discriminate against it. Neutrality was now at an end except to the extent of a formal declaration to that effect. Two months later the "Robin Moor," a neutral U.S. vessel, was sunk by a German submarine on the high seas, the passengers and crew being left afloat in small lifeboats. The president, in describing the act to congress, branded the sinking of the "Robin Moor" as "the act of an international outlaw."

Neutrality ended for the United States with the Japanese attack at Pearl Harbor on Dec. 7, 1941. A month or more later the foreign ministers of the American republics met at Rio de Janeiro, and, after reaffirming their pledge that an act of aggression against one of them would be considered as an act of aggression against all, recommended the breaking of diplomatic relations with the Axis powers. A number of them promptly declared war, but even for the rest neutrality was over. For other states, previously neutral, the status ceased to have any technical meaning.

Effect of the Charter of the United Nations.—The underlying assumption of the charter of the United Nations, as had been that of the covenant of the League of Nations, was that the old right of individual states to have recourse to armed force was, except in case of individual or collective self-defense, the prerogative of the collective group acting through the Security council looking to the suppression of acts of aggression and the maintenance of the general peace. Such collective action as might be decided upon by the Security council would not be "war" in the technical sense, so that states not participating in the measures taken would not be "neutral" in the traditional sense. While there is no obligation, except by special agreement, for every member to take part in military measures of enforcement, there is the

obligation of affording mutual assistance in carrying out the measures decided upon by the Security council, which would preclude any claim of the traditional neutral rights.

But what if a conflict of ideologies and military policies between the leading members of the United Nations should reach the point where the system of collective security might prove to be unworkable? What then would be the attitude of third states that could not risk taking sides between the two powerful contenders, now become more powerful with the discovery of a weapon of devastating power? A new position of "neutralism" developed, not one of claiming rights as against the two possible belligerents, but a position of remaining as completely aloof as possible from the impending conflict, which might at any time pass from that of a cold war to a fighting one over which it was clear that the Security council could exercise no control (*see* NEUTRALISM). A war in violation of the provisions of the charter could not be expected to keep within the traditional laws of war. The atomic bomb had eliminated the old distinctions between combatants and noncombatants, making the risk of participating even in discussions of the Security council too great for the defenseless nation. Specific application of the new status of neutrality was given by the Declaration of the 14-nation conference at Geneva in 1962 by which Laos was recognized as a neutral state and on its part pledged itself to remain neutral. Meanwhile Switzerland, while not a member of the United Nations, retained its old status as a neutral under the covenant of the League of Nations, and Austria, on becoming a member of the United Nations, was recognized as having a similar status. *See* WAR; INTERNATIONAL LAW, PUBLIC; UNITED NATIONS. *See* also references under "Neutrality" in the Index.

NEUTRALIZATION is a setting of limitations upon the belligerent capacities of a sovereign state, which thereupon becomes bound not to do or to suffer certain things, such as the building of fortifications or the presence or passage of armed forces in a defined area. This area is usually smaller than the whole territory of the state, but a similar situation may be created in respect of a whole state, when that state undertakes not to take part in wars except in self-defense. The resulting situation is in this case commonly called perpetual neutrality. For instance, when Austria's status was regulated by the state treaty of 1955, Austria unilaterally and voluntarily declared by a separate instrument that it would be perpetually neutral, defend its neutrality, join no military alliances and allow no foreign bases on Austrian territory. The state treaty prohibited Austria from possessing atomic and similar weapons. Neutralization agreements affect other states, if and so far as these assume obligations in the event of a breach of the agreement or if they undertake themselves to abstain from certain actions.

A state is not, of course, bound by a neutralization agreement which it has not signed, and therefore the only way to ensure complete immunity from attack is by a universally signed convention. In practice, considerations of geography and comparative power determine what signatures are necessary to make a particular agreement effective.

Neutralization, which is the outcome of agreement, is to be distinguished from neutrality (*q.v.*), which is an attitude adopted by a state at will, in face of a particular situation, and for no specifically prescribed period—as, for instance, with Sweden or the Republic of Ireland during World War II, these states choosing to remain outside the contest.

Among islands, Corfu was neutralized upon its cession to Greece in 1863, Spitsbergen (Svalbard) and Ahvenanmaa (the Aland Islands) were neutralized in 1920 and 1921 respectively. Norway undertook in 1920, by a convention signed by eight other states, not to build a naval base in Spitsbergen or to use it for any military purposes. Russia, which acquired Ahvenanmaa from Sweden in 1809, agreed in 1856, upon the insistence of Sweden and other powers, not to fortify the islands or to maintain any military or naval establishment in them. After World War I Finland, to which the islands then passed, gave a similar pledge in a convention signed in 1921 in company with nine other states (excluding the U.S.S.R.); this promise was repeated in 1947 in the peace treaty with Finland.

Instruments declaring the neutrality of whole states were signed in respect of Switzerland in 1815, of Belgium in 1839, of Luxembourg in 1867 and of the Vatican city-state in 1929 (the last was signed only by the Holy See and Italy). Switzerland continued to maintain its neutrality, but Belgium abandoned that attitude after World War I and Luxembourg after World War II.

(P. J. A. C.)

NEUTRON, a particle in the atomic nucleus which has no electrical charge. The discovery of the neutron played an important part in opening the way for the utilization of nuclear energy. Fission of the atomic nuclei of various isotopes of uranium, plutonium, etc., it was learned, could be induced by bombarding them with the neutral particles. In this process, additional neutrons are released, making possible the so-called chain reaction. This is the principle of the fission bomb developed during World War II. Also, the released energy has been harnessed for industrial use by controlling the reaction so as to prevent it from going substantially beyond the point where the chain reaction is self-sustaining.

The neutron and the proton are now considered to be the basic building materials of which all atomic nuclei are composed. The neutron has a mass slightly greater than that of the proton.

History.—Following publication in 1911 of his concept of the atom as a structure built around a nucleus, Lord Rutherford conducted experimental studies of the atomic disintegration of light elements. In 1920, in a lecture to the Royal Society, he offered laboratory proof that the long-range particle emitted by nitrogen under bombardment with alpha rays is the proton, which is the nucleus of the hydrogen atom and part of the nucleus of all other atoms. The proton is the simplest of all nuclei, and carries a positive electrical charge.

With the discovery of this first nuclear reaction, Rutherford's nuclear hypothesis was further validated. He then offered still another hypothesis. The observed reactions of the proton, he said, were consistent with the supposition that it was linked with another, still undiscovered constituent in the nucleus—a particle that was electrically neutral.

In 1932, Sir James Chadwick demonstrated that the radiation created when beryllium is bombarded by alpha particles consists of a stream of nuclear particles carrying no electrical charge. Rutherford's hypothetical particle, now an established fact, was named the neutron. Earlier, Frédéric Joliot and Mme. Irène Joliot-Curie in Paris had investigated this penetrating radiation emitted by beryllium when bombarded by alpha particles. They found that the radiation which had previously been interpreted by W. Bothe and H. Becker as a gamma radiation (*see* RADIOACTIVITY), was capable of propelling hydrogen nuclei (protons) with very high speed. Chadwick, after a thorough experimental investigation of all the properties of the new radiation, came to the conclusion that it must consist of neutral particles of a mass nearly equal to that of the proton. The major argument in this conclusion was the speed given by the newly discovered particle to various atomic nuclei in collisions. The assumption of a massive particle rather than a gamma ray brought order into the experimental observations.

It was soon found that neutrons, because of their lack of electric charge, are particularly effective in causing nuclear transformations (*see* ATOM; NUCLEUS). In 1934 Enrico Fermi and his collaborators showed that nearly every element in the periodic table may undergo a nuclear transformation when bombarded by neutrons. In many cases, radioactive isotopes of the elements are formed in this way (*see* ISOTOPE: *Radioactive Isotopes*). Slow neutrons were found particularly useful in producing these transformations.

Fermi found that uranium was among the elements in which neutron bombardment induced transformations. This element was investigated in greater detail by Lise Meitner and Otto Hahn in Berlin in subsequent years. Their results were difficult to interpret, until late in 1938 Hahn and F. Strassmann found that at least one of the radioactive elements formed by bombardment of uranium was an isotope of barium. This was immediately interpreted by Otto Frisch and Meitner (also two weeks later and independently, by Hahn and Strassmann themselves) as indicating that the uranium nucleus had been split into two massive fragments, a process later called fission. The important technical developments resulting from this discovery will be described in a later section of this article.

Properties of Free Neutrons.—It is appropriate to discuss the properties of the neutron by comparing them with those of its counterpart in the atomic nucleus, the proton.

The neutron, as already mentioned, has no electric charge, whereas the proton has one positive elementary charge (1.6×10^{-19} coulombs). This causes great differences in the passage of the two particles through matter: a fast-moving proton ejects electrons from atoms which it encounters, and thereby produces heavy ionization along its path with consequent loss of energy. Because of this, the track of a proton can easily be observed in a cloud chamber. The neutron, having no electric charge, cannot produce ions but can only make direct collisions with atomic nuclei. Its track, therefore, cannot be observed, but the presence of neutrons can be deduced from the visible tracks in a cloud chamber of charged recoil nuclei which have been set in motion by neutron impact. (See *Detection of Neutrons*, below.)

Another consequence of the absence of ionization is that neutrons do not lose energy so long as they do not collide with atomic nuclei. Since such collisions are very rare, a neutron travels far through matter before losing its speed. Protons, on the other hand, travel only very short distances because they lose their energy by ionization. For instance, a proton with a velocity of 3×10^9 cm./sec., which is the order of magnitude of the velocities common in nuclear physics, will travel about 0.005 cm. in a material such as iron or copper. A neutron of the same velocity will travel about 5 cm. before it makes its first collision with a nucleus, and since it loses only a fraction of its energy in each collision, it will continue to travel for 10 to 100 times this distance before it is finally captured by a nucleus. Neutrons are, therefore, very penetrating.

Mass.—The mass of the neutron is very nearly the same as that of the proton. In the physical scale of atomic weights (in which the isotope C^{12} has a mass of exactly 12), the mass of the neutron is 1.00867. On the same scale, the mass of the hydrogen atom is 1.00797 and that of the proton 1.00728. The neutron is, therefore, slightly heavier than the proton and even slightly heavier than the hydrogen atom (proton plus electron).

The fact has two important consequences. First of all it makes the neutron unstable and subject to beta disintegration (*see* below).

The second consequence is that the neutron cannot be considered as a proton and an electron bound together in some way. Therefore, the neutron and the proton have to be regarded as fundamental particles which are closely related to each other in a manner the details of which were still unknown as of the mid-1960s, although by that time much was known of the forces between them. The view then gaining currency was that protons and neutrons were simply two different charge states of the same entity called the nucleon.

Spin, Magnetic Moment and Statistics.—Just like the more familiar fundamental particles, the electron and the proton, the neutron has a "spin"; *i.e.*, it has properties which are analogous to those of a spinning top. The value of the spin (angular momentum) is $\frac{1}{2}(h/2\pi)$, where h is Planck's constant, just as for proton and electron. It also shares with proton and electron the property of obeying Fermi-Dirac statistics, which makes it impossible for two neutrons in an atom to be in the same quantum state. The value of the spin and the fact that neutrons obey Fermi-Dirac statistics are further arguments against the interpretation of the neutron as a combination of electron and proton.

The neutron has a magnetic moment whose direction is opposite to that of its spin, as if a negative electric charge were revolving in the rotation of the spinning top. The value of the magnetic moment has been measured with great accuracy and is 1.9135 nuclear magnetons. This is defined in terms of the mass M of the proton as $eh/4\pi Mc$. The proton has a positive magnetic moment (as if a positive charge were revolving) whose value is 2.7928 nuclear magnetons. The magnetic moment of the electron is negative and is almost one Bohr magneton (about 1,840 nuclear magnetons).

Beta Decay.—According to the theory of radioactive beta decay (*see* RADIOACTIVITY), the process taking place is $n \rightarrow p + \beta^- + \bar{\nu}$, indicating the formation of a proton p, negative electron β^- and antineutrino $\bar{\nu}$, respectively. This fundamental process was first observed for free neutrons in 1949. A. H. Snell and collaborators at Oak Ridge, Tenn., detected the simultaneous occurrence of a proton and an electron coming from the decay of neutrons in a high intensity beam issuing from the nuclear reactor (see *Nuclear Energy*, below). In 1950 John M. Robson at Chalk River in Canada observed the decay of the neutron and also measured the energy spectrum of the decay electrons. In a sensitive mass spectrometer he identified the heavy particles as protons. The negative particles in coincidence with the protons were detected in a beta ray spectrometer which measured the electron energy. The observed maximum energy of the decay electrons gives a value for the mass of the neutron which compares very well with the more accurate measurements (*see* above) made from observations on numerous nuclear transmutations in which all the masses and energies, except the neutron's mass, are known.

Free neutrons decay according to the usual laws of radioactive decay. Robson deduced a value for the half life of the neutron of 10.2 min., in excellent agreement with the value estimated from theory; in the 1960s the value was given as 12 min.

Wave Properties.—Quantum mechanics postulates that every particle exhibits wave properties with a characteristic wave length $\lambda = h/mv$, where λ is the wave length, h is Planck's constant, and mv is the momentum of the particle. Neutrons are no exception and the existence of this property gave rise to an active field of research in neutron optics. Experimental methods for obtaining monochromatic neutrons, or neutrons of a single momentum, and ways of measuring their diffraction by crystals were devised, much as X-rays were used to study crystals. Because neutrons are strongly scattered by lighter nuclei, as mentioned below, they help to disclose the part taken by light atoms in crystal lattices where X-rays are affected scarcely at all. Promising results are found in the study of magnetic substances. As the neutron has a magnetic moment but no electric charge, passage of a neutron beam through strongly magnetized iron causes the neutrons to show polarization effects not exhibited by other particle waves. A slow neutron of kinetic energy 0.13 electron volts has a particle wave length of 1×10^{-8} cm. (1 Å). Neutrons that, as a result of collisions, have come into equilibrium with their surroundings are called thermal neutrons. Their average energy is about 0.025 electron volts, hence, their particle wave lengths are about 5 Å. The marked resonance absorption of slow neutrons appears to be closely linked with this wave nature of the neutron and its likelihood of being captured for appreciable lengths of time within the potential barrier of a nucleus.

Neutrons as Building Blocks of Nuclei.—According to present theory, all nuclei are composed of neutrons and protons. The theory replaced the older one, now completely discarded, that protons and electrons were the building stones of the nucleus. Even before the discovery of the neutron, this older theory had encountered grave difficulties. For example, according to quantum mechanics, electrons cannot be compressed into such a small space as the inside of a nucleus. Additional arguments arise from the spin and the statistics of atomic nuclei, and the peculiar phenomena connected with beta radioactivity.

The proton-neutron hypothesis has met with considerable success, however, and has been used to explain a number of fundamental properties of atomic nuclei. It is well established that protons

and neutrons inside the nucleus can be considered to conform to the laws of quantum mechanics.

According to the proton-neutron hypothesis the atomic number Z (charge) of a nucleus is equal to the number of protons contained in it. The mass number A, *i.e.*, the integer nearest to the atomic mass, is the sum of the numbers of protons and neutrons since each of these particles contributes about one atomic mass unit. The isotopes of a given element, therefore, all contain the same number of protons but varying numbers of neutrons; for instance, whereas any isotope of the element carbon contains 6 protons, the most abundant isotope C^{12} contains in addition 6 neutrons, while the less abundant stable isotope C^{13} contains 7 neutrons, the radioactive isotope C^{14} contains 8 neutrons and C^{11} contains only 5 neutrons.

Perhaps the most important information about a nucleus is provided by its exact weight. From it the binding energy of the nucleus can be deduced, with the help of Einstein's relation, $E = mc^2$. For instance, the helium nucleus has a mass of 4.00288. Since its atomic number is 2 and its mass number 4, it contains 2 neutrons and 2 protons; the combined weight of these 4 particles is 4.03300. The difference between this and the weight of the helium nucleus represents the binding energy with which the 4 particles are held together in the nucleus. The energy represented by this mass difference is tremendous. The formation of 4 g. of helium from 2 g. of hydrogen and 2 g. of neutrons would release as much energy as the burning of about 100 tons of coal if such a process of fusion could be brought about.

A binding of this tremendous strength cannot be the result of electric forces; moreover, no such forces act on neutrons anyway, because of the absence of electric charge. Gravitational forces are even more inadequate to account for the strong binding. A new force must therefore be assumed, which is known as nuclear force. The exact character of nuclear forces was only partially known as of the mid-1960s; however, it was known that they act only over very short distances, having a range of about 3×10^{-13} cm. and being negligible outside this range. The exploration of nuclear forces is the prime objective of nuclear physics. The scattering of neutrons of various velocities by protons has given fundamental information about nuclear forces.

Neutron-neutron and proton-proton forces are found to be about equal within the nucleus, and there is a strong tendency for equal numbers of neutrons and protons to form the lighter atoms. In the heavier atoms, the number of neutrons exceeds that of protons. For example, uranium-238 has 92 protons and 146 neutrons; uranium-235 has the same number of protons but only 143 neutrons. The separation energy of a neutron, or the energy that must be supplied to extract a neutron from a nucleus, ranges from 5 to 13 Mev (million electron volts) except for some of the lighter elements to be mentioned below.

Neutron Production.—Since the neutron is not stable and is readily captured by a nucleus (see *Properties of Free Neutrons*, above, and *Nuclear Reactions Produced by Neutrons*, below), few neutrons are found in nature in the free state, *i.e.*, outside of atomic nuclei. Therefore, if an experimenter wishes to work with neutrons, he must produce them by means of nuclear reactions. These reactions fall into three types: (1) reactions initiated by an energetic charged particle, such as the nucleus of light or heavy hydrogen or helium, commonly called proton, deuteron and alpha particle, respectively; (2) reactions initiated by gamma rays (electro-magnetic radiation); (3) nuclear fission.

Reactions Produced by Charged Particles.—This type of reaction was historically the first method to produce neutrons and, until 1942, the only way to produce them in quantity. It is still the most versatile method, being capable of producing neutrons of specified kinetic energy. Chadwick, in his first experiments, obtained neutrons by bombarding beryllium or boron with alpha particles, according to the nuclear equation $He^4 + Be^9 \rightarrow C^{12} + n^1 + Q$ where Q, the increase in kinetic energy, is in this case 5.76 Mev. With the growing prevalence of high-energy accelerators, neutrons were mostly produced by bombarding various atomic nuclei with deuterons and sometimes with protons, accelerated in a cyclotron or some similar device. This has the advantage that the number of particles obtainable is very much greater than the number of alpha particles emitted by available amounts of radioactive material, and neutrons of much higher energies than those from natural sources are available. This has led to a great expansion in the nuclear particles being studied (*see* PARTICLES, ELEMENTARY). Particular nuclear reactions useful for the production of neutrons will be discussed below.

One of the prime considerations for choosing a particular nuclear reaction for the production of neutrons is the yield. This depends sensitively on the kinetic energy of the bombarding particle, and on the nature of the bombarding particle as well as that of the target nucleus. The bombardment of beryllium with deuterons gives in general a higher yield than any other combination of nuclei. However, even for this reaction, the yield is very small and changes rapidly with the energy of the deuterons: at 1 Mev deuteron energy, it is about 1 neutron for 100,000 deuterons; at 10 Mev, about 1 in 1,000, and further increase of the deuteron energy, to 40 Mev is expected to increase the yield to about 1 in 100. The yields are so small because the deuteron loses kinetic energy continuously by ionizing the atoms of beryllium through which it passes, and in general it will have lost all its energy before it has had a chance to hit a beryllium nucleus and disintegrate it. A cyclotron may give a current of deuterons of about 100 microamperes; if the deuteron energy is 10 Mev, this will produce about 10^{12} neutrons per second.

The yield from the bombardment of beryllium with alpha particles is about 1 neutron for 4,000 alpha particles (if the alpha particles comes from radon). One curie of radon (*i.e.*, the amount which is in radioactive equilibrium with 1 g. of radium), intimately mixed with beryllium will give about 10,000,000 neutrons per second. An average cyclotron is thus equivalent in neutron production to about 100,000 curies, *i.e.*, to the radioactive rays from 100 kg. of radium.

At very low energy the yield decreases rapidly. The reason is that the incident particle (deuteron or alpha particle) cannot come close to the beryllium nucleus because there is a strong electrostatic repulsion between them, and there is not sufficient kinetic energy to overcome this repulsion. For instance, the yield for deuterons of 500,000 ev (electron volts) on beryllium is only 1 neutron per 2,000,000 deuterons, and at 250,000 ev it is immeasurably small.

Neutrons can also be produced by deuteron bombardment of other light nuclei such as deuterium, lithium, boron, nitrogen, etc. The yields are usually smaller by a factor of between two and ten than the yields from beryllium at the same energy.

In any nuclear reaction energy is either released or absorbed. When neutrons are produced from deuterons, there is normally an energy release because the proton is not very strongly bound to the neutron in the deuteron and can be bound more strongly to the target nucleus. For instance, with a beryllium target, the energy release is 4 Mev; with a deuterium target, 3 Mev. Higher energy releases are obtained from lithium or boron targets, namely 15 and 13 Mev, respectively. These targets can, therefore, be used to produce very high energy neutrons from deuterons of quite low kinetic energy, which can be accelerated by apparatus of only moderate size and cost. Still higher energy neutrons can be obtained by deuteron bombardment of tritium, the hydrogen isotope of mass 3, with an energy release of 18 Mev; this reaction is also useful because of its high yield at deuteron energies of a few hundred thousand volts.

An important problem in experiments on fast neutrons is the obtaining of neutrons of a well-defined energy (monochromatic neutrons). In general, a nuclear reaction will give neutrons of many different energies because the residual nucleus (which remains after emission of the neutron) can be left in several different energy states. Thus, the deuteron bombardment of boron gives, besides the fast neutron group with 13 Mev energy release, at least 3 other groups with energy releases of 9, 6 and 4 Mev, respectively; the reaction with lithium gives neutrons of all energies below the maximum, and that with beryllium also gives many energy groups.

On the other hand, the reaction between two deuterons is satis-

factory because in this case the residual nucleus (helium 3) does not have any excited states. The deuteron-deuteron reaction $H^2(d,n)He^3 + 3.28$ Mev has, therefore, been an important reaction for producing monochromatic neutrons. The reaction between tritium and the deuteron also fulfils this criterion and at the same time gives very high energy neutrons according to the reaction $H^3(d,n)He^4 + 17.6$ Mev, where H^3 stands for tritium and d for deuteron.

Neutrons can also be produced by bombarding a nucleus with protons. In this case energy is always absorbed and the reaction, therefore, begins to take place only above a certain kinetic energy of the proton, the threshold energy. Measurement of this threshold energy is valuable in making accurate comparisons between the masses of atomic nuclei and has given an accurate value of the mass of the neutron. The reaction between lithium 7 and a proton $Li^7(p,n)Be^7 - 1.65$ Mev gives monochromatic neutrons with high yield, and is valuable for the accurate study of neutrons of moderately low kinetic energy, so long as the energy of the incident protons is not too high.

Neutron Production by Gamma Rays.—Neutrons can be released from nuclei by gamma rays, *i.e.*, by electromagnetic radiation of extremely short wave length. The energy of one quantum of gamma radiation, $h\nu$, must be greater than the energy with which the neutron is bound to the rest of the nucleus. In most nuclei this separation energy is about 8 Mev; notable exceptions are beryllium $Be^9(\gamma,n)Be^8 - 1.67$ Mev and deuterium $H^2(\gamma,n)H^1 - 2.23$ Mev for which the separation energies are 1.67 and 2.23 Mev, respectively.

The yield of neutrons is very small, even for gamma rays of high energy. Average yields are about 1 neutron for 1,000 gamma rays if sufficient material is provided to absorb the gamma rays (this requires a thickness of several centimetres of iron or about a metre of beryllium); in thin layers, the yield is proportionally less. The efficiency of gamma rays in producing neutrons usually rises with increasing gamma-ray energy and reaches a maximum at a gamma-ray energy of about 15 to 20 Mev per quantum.

Neutron Production by Fission.—In the fission of uranium and other heavy nuclei, neutrons are emitted. This is the basis of the nuclear chain reaction which is the most economical means of producing large quantities of neutrons.

The fission of uranium can be induced by neutrons; in each fission one neutron is absorbed whereas more than one neutron is emitted. Each of the emitted neutrons can in turn produce fission in another uranium nucleus provided (1) the neutrons are not absorbed by other nuclei, and (2) a sufficient amount of uranium is used to prevent escape of the neutrons. In this way a nuclear chain reaction is obtained in which neutrons are continuously produced by fission and in turn cause fission in other nuclei.

There is virtually no limit to the number of neutrons that can be produced in this way. The only practical limitation comes from the considerable amount of energy released in fission which must be dissipated. If 100,000 kw. can be dissipated or used in production of useful power, more than 10^{18} neutrons per second are produced; one such reactor thus gives a neutron production equivalent to the output of 1,000,000 cyclotrons. However, for experimental purposes it is necessary to remember that the neutrons will be distributed over a larger area, making their density per unit area not much greater than that from a cyclotron, and the neutrons also will be of lower energy, in general, than those from a cyclotron. In addition, in working with larger numbers of neutrons, the health hazards must be considered. But despite these shortcomings, intense beams of neutrons from nuclear reactors are commonly used for experiments.

Nuclear Reactions Produced by Neutrons.—The most important physical property of neutrons is the absence of electric charge. This enables them to approach an atomic nucleus without being repelled by its positive charge. Therefore, a neutron can enter an atomic nucleus no matter whether it is fast or slow. On the other hand, a charged nuclear particle like a proton or deuteron can enter a nucleus only when it has a sufficiently high velocity to overcome the electric repulsion; hence the usefulness of a charged particle for producing nuclear reactions is exhausted after it has been slowed down. Accordingly, the yield of nuclear reactions produced by a charged nuclear particle is only of the order of 1 in 1,000 or less (see *Reactions Produced by Charged Particles*, above); on the other hand, the yield of nuclear reactions from very slow neutrons is nearly 100%; almost every neutron which is produced will ultimately be captured by a nucleus and will produce some nuclear reaction.

Several types of reaction between neutrons and atomic nuclei will be discussed below. Which of these reactions takes place in any given collision between neutron and nucleus is a matter of chance; the probability of any given type of reaction depends on the particular nucleus with which the neutron collides, and on the velocity of the neutron. Some reactions, notably the capture of neutrons with the emission of gamma radiation, are enhanced by reducing the velocity of the neutrons while others can be initiated only by fast neutrons.

Scattering of Neutrons.—The simplest process which may occur when a neutron hits an atomic nucleus is scattering, *i.e.*, a change of the direction in which the neutron moves. This scattering may be elastic like the collision between two billiard balls; in this case, the kinetic energies of the neutron and the nucleus after the collision add up to the kinetic energy of the neutron before the collision; or the scattering may be inelastic, *i.e.*, kinetic energy may be lost and transformed into internal energy of the bombarded nucleus.

At relatively low neutron energy, elastic scattering takes place in collisions between neutrons and protons, although neutron capture to create deuterons also occurs. A neutron of nearly any energy may give rise to resonant capture, with radiation of gamma rays and consequent loss of kinetic energy of the neutron. Above about 0.1 Mev, inelastic scattering becomes rapidly more important and predominates over elastic scattering when fast neutrons collide with heavy nuclei. In the majority of cases, a very large fraction of the kinetic energy is lost in inelastic collisions, so that the neutrons emerge after the collisions with an average kinetic energy of about one-quarter of their initial energy or less. The remainder of the energy has been transformed into excitation energy of the nucleus and usually appears afterward in the form of gamma rays.

At very high neutron energies, above 100 Mev, new fission processes begin, resulting in the production of "stars" in photographic emulsions. This is the experimental region in which many of the so-called strange particles originate. In the mid-1960s these particles were still the object of detailed study.

Collisions between neutrons and atomic nuclei are, of course, relatively rare because of the very small size of the atomic nucleus. This size can be determined from the frequency of collisions with fast neutrons. The frequency of collisions is commonly measured in terms of the effective cross section, *i.e.*, the target area which the nucleus appears to present to the neutron. If the cross section is σ, a thin slab of material, of thickness t and containing N nuclei per unit volume, will scatter (or absorb) a fraction

$$f = N\sigma t$$

of the neutrons incident upon it. The cross section σ is conveniently determined by measuring the fraction, $1\text{-}f$, of neutrons which penetrate the slab without being deflected.

The cross sections of nuclei for collisions with fast neutrons are all of the order 10^{-24} sq.cm. This corresponds to a radius of the nucleus of about 10^{-12} cm., which confirms the result obtained from other experiments. A unit of area 10^{-24} sq.cm. has become commonly known as a "barn." Neutron scattering experiments further confirm that the volumes of nuclei are roughly proportional to the number of particles contained in them, *i.e.*, to the atomic weight. The most important deviation from this rule is that the lightest nuclei tend to present a relatively greater cross section to neutrons of moderate energy (a few million electron volts). In solid materials neutrons travel on the average about 2 to 10 cm. between collisions.

For the theory of nuclear forces, the scattering of neutrons by protons is particularly important. The effective cross section of the proton for slow neutrons is unusually large, namely about

20×10^{-24} sq.cm., whereas that of the nuclei of such elements as aluminum, silicon, etc., is only about 2×10^{-24} sq.cm. The large cross section of the proton has been explained in terms of a resonance effect. At higher neutron energy, the proton cross section decreases but it is still 3×10^{-24} sq.cm. for neutrons of 2 Mev and falls in line with heavier nuclei only at extremely high neutron energy.

Whether the scattering is elastic or inelastic, some kinetic energy will be transferred from the neutron to the nucleus. The scattering is connected with a slowing of the neutron, which will be discussed in more detail under *Neutron Diffusion*, below.

Nuclear Reactions Leading to the Emission of Charged Particles.—In many cases the collision between a neutron and a nucleus leads to a true nuclear reaction in which a nuclear particle other than a neutron is emitted. These reactions are the inverse of the reactions in which neutrons are produced by an incident-charged particle. The likelihood of a nuclear reaction is dependent to an important degree on the time a neutron spends in the neighbourhood of the target nucleus, as expressed by the $1/v$ relationship, which shows the probability of such events to vary inversely with the velocity of the neutron.

Many reactions have been observed in which a proton or an alpha particle is emitted when a nucleus is bombarded by a neutron. These are designated as (n,p) and (n,α) reactions respectively. Reactions in which a proton is produced in general absorb energy and can, therefore, be caused only by neutrons of considerable kinetic energy. There are some exceptions, the most important being the reaction $n + N^{14} \rightarrow p + C^{14}$ which releases an energy of 0.6 Mev; this reaction is caused with considerable probability by very slow neutrons, and occurs in the atmosphere where neutrons of cosmic ray origin form radioactive C^{14} from atmospheric nitrogen. Archaeological dating by the activity of C^{14} in organic remains is based on the assumption of a constant supply of C^{14}, of half-life 5,600 years, and its uniform distribution in the carbon of living matter.

The reactions in which alpha particles are emitted often release energy. The most important ones of this type are the reactions of neutrons with lithium-6 and with boron-10; the cross section for these reactions is extremely great, especially for slow neutrons: 4,000 barns for $B^{10}(n,\alpha)Li^7$; 10,900 barns for $Li^6(n,\alpha)H^3$.

Many neutron-induced nuclear reactions lead to the formation of a radioactive nucleus, which subsequently emits a beta ray (electron). An example is the nucleus C^{14} mentioned above. It can be shown from general arguments about nuclear stability that all reactions caused by a neutron in which a proton is emitted lead to a radioactive nucleus. If an alpha particle is emitted in the reaction, the resulting nucleus may or may not be radioactive; for instance, in the cases mentioned above, the reaction between neutrons and lithium-6 leads to the important radioactive isotope of hydrogen of mass 3, whereas the reaction with boron-10 gives the stable nucleus lithium-7.

Reactions Leading to the Emission of Several Neutrons.—When a neutron of very high energy (more than 10 Mev) hits a nucleus, 2 or more neutrons are frequently emitted from the nucleus. In the case of heavy nuclei and of neutrons of sufficiently high energy, theory shows that this $(n,2n)$ reaction is the most likely process to occur. If two neutrons are emitted, the bombarded nucleus loses one unit of weight; this results frequently in a radioactive nucleus which emits positrons (positive electrons). Reactions of this type are often useful because they provide specific detectors for neutrons of high energy.

Capture of Neutrons.—Neutrons colliding with an atomic nucleus may simply be captured and incorporated into the nucleus, the energy of binding and the kinetic energy of the neutron being transformed into the energy of one or several gamma rays in an (n,γ) reaction. In many instances, neutron capture leads to the formation of a radioactive nucleus which subsequently emits beta rays as in C^{14}; this makes the capture easily observable and makes it possible to use this process for the detection of neutrons. The probability of capture varies greatly; it is generally greater for slow than for fast neutrons, and greater for heavy than for light nuclei. For fast neutrons and light nuclei the capture probability is immeasurably small, but for heavy nuclei about 1 collision in 20 to 200 leads to capture. The capture cross section for most nuclei for slow neutrons is less than 10 barns. Notable exceptions are found in the cases of boron, cadmium and gadolinium, with cross sections of 430, 2,100 and 22,000 barns, respectively. For slow neutrons and light nuclei, scattering still predominates over capture, *e.g.*, in ordinary hydrogen in the ratio 200 to 1, and in heavy hydrogen or carbon even more strongly.

Accordingly, neutrons have very different lifetimes in different substances, the lifetime being the average time from the production of the neutron until it is captured (or causes a nuclear reaction). In solid boron, this time is about 1×10^{-7} sec., in most solids of high atomic weight about 1×10^{-4} sec., in such special substances as graphite it becomes more than 1×10^{-2}, while in gases it ranges from about $\frac{1}{10}$ sec. for air to many seconds in pure heavy hydrogen. Even the longest of these times is short compared with the half life (10.2 min.) of the neutron as a radioactive particle.

The capture of slow neutrons shows the interesting phenomenon of resonance. For each nucleus there exist certain characteristic values of the kinetic energy of the neutron which make the capture of the neutron very likely. For instance, cadmium absorbs very strongly all neutrons less than 0.4 ev, indium absorbs neutrons of 1.4, 4 and 9 ev., gold those of 5 ev., whereas iodine has resonances at about 20, 30 and 40 ev and some at higher energies. The resonances are very sharp; *e.g.,* indium absorbs strongly only neutrons between 1.2 and 1.7 ev, and its capture cross section at 1.44 ev is nearly 1,000 times as large as that at 2.5 ev. To study these neutron resonance levels, special devices, known as velocity selectors, have been built which measure the time of flight of the neutron from its source to a detector. Studies of resonances give important information on the structure of nuclei; in fact, the resonance effects in the capture of slow neutrons gave rise to the modern theory of the compound nucleus, first developed by Niels Bohr, which forms the basis for the general understanding of reactions involving heavy nuclei.

Fission.—Neutrons can produce fission in heavy nuclei, especially in uranium, thorium and plutonium. Fission consists in the splitting of the heavy nucleus into two parts of approximately equal weight. This is possible because the mass energy in the heavy nucleus is considerably greater than the sum of the mass energies in the two nuclei of medium weight which are produced by fission. The difference in mass energy is released in kinetic energy of the fragments; it is approximately 200 Mev per fission. In a 1,000,000 kw. power plant approximately 1 kg. of uranium must undergo fission per day.

The use of fission for practical purposes is based on the fact that neutrons are emitted in the fission process and that more than one neutron is emitted per fission. As was pointed out in *Neutron Production by Fission*, above, this process is the most suitable one for the practical production of neutrons in large quantities. For example, in the Arco reactor (Idaho) and the Dido reactor at Harwell, Eng., a neutron flux density in excess of 10^{14} per sq.cm. per second was obtained.

Detection of Neutrons.—One of the most important problems in neutron experiments is the detection of the neutrons. Since the neutron produces no direct ionization, it can be detected only through its interactions with other nuclei. Four types of effects may be used for the detection of neutrons, viz.:

(1) The recoil of a nucleus with which a neutron has collided; (2) the emission of charged particles in a nuclear reaction produced by a neutron; (3) the production of a radioactive nucleus by any nuclear reaction caused by the neutron (this reaction may be simple capture), and (4) the production of "stars" in photographic emulsions by high-energy neutrons, a special case of (2).

The first effect will occur only with fast neutrons and can, therefore, be used only to detect these neutrons; on the other hand, it has the advantage that it permits the determination of the energy of the neutron. The second and third effects can be used for the detection of slow as well as fast neutrons; different nuclear reactions are used in the two cases. The fourth effect has been used to study energetic nuclear reactions, the production of mesons and the "strange" particles.

Fast Neutron Detectors.—*Recoil Detectors.*—In an elastic collision between a neutron of mass m and a nucleus of mass M the latter receives the kinetic energy

$$E' = \frac{4mM}{(M+m)^2} E \cos^2 \theta$$

where E is the kinetic energy of the neutron before the collision and θ is the angle between the direction of motion of the incident neutron and the recoil nucleus. For ease of observation, a large kinetic energy of the recoil nucleus is usually desirable; therefore, protons are preferred because their mass M is practically equal to that of the neutron. If the recoil proton goes in the same direction as the incident neutron it will receive the entire kinetic energy of the latter, as shown above, since $\cos^2 \theta = 1$ and $m = M$.

Protons are also preferred because the probability of their collision with a neutron is particularly large and can be calculated with accuracy on theoretical ground. Furthermore, the recoil protons produced by neutrons of a given energy E are distributed uniformly in kinetic energy from 0 to E, which simplifies the determination of the energy of neutrons.

The most important types of proton recoil detectors are cloud chambers filled with hydrogen or a gaseous hydrogen compound, photographic emulsions, ionization chambers with linear pulse amplifiers, and organic scintillators. The cloud chamber or emulsion is then exposed to neutrons coming from a definite direction and the direction as well as the length of the proton tracks are observed. From the length of the track the energy of the proton can be deduced. In an ionization chamber the energy is measured by the number of ions formed (by a single proton). The ionization chamber can be filled with hydrogen or provided with a layer of paraffin or some other solid material containing hydrogen. For the observation of large numbers of neutrons and determination of their energy, the ionization chamber is a satisfactory instrument.

The efficiency of neutron counters is usually low because of the small probability of collision between neutrons and nuclei. However, thick plastic organic scintillation counters may detect as many as 50% of incident neutrons. These counters produce an output of light that is proportional to the energy of the recoil particles. A proton recoil counter containing a thick layer of paraffin in an ionization chamber is the most efficient counter known for fast neutrons. If the neutron energy is E Mev, the counter will give about $2E$ pulses for every 10,000 neutrons incident upon it. Thin paraffin layers, of course, give even smaller efficiency but are more convenient for measuring the neutron energy. "Thick" and "thin" are to be understood in comparison with the range of the recoil protons. "Long counters" for recording high-energy neutrons rely upon the passage of the particles through a region containing paraffin as a moderator, in which the neutrons are slowed to the $1/v$-law range and then detected in boron trifluoride gas.

Deuterons and alpha particles have also been used successfully for the observation of neutrons by the recoil method. The recoil of still heavier nuclei, such as carbon, appears mainly as a disturbing effect when compounds such as paraffin are used in a recoil detector.

Nuclear Reactions.—The $B^{10}(n,\alpha)Li^7$ reaction of neutrons with boron-10, giving alpha particles, can be used for the detection of fast neutrons. An unsatisfactory feature of this detector is that the reaction is produced with much higher probability by slow neutrons than by fast ones.

Fission is a very convenient means of detecting neutrons, because it gives rise to very large pulses of ionization which can easily be distinguished from any disturbing effect. It is usually desirable that the detector respond only to fast neutrons (above 1 Mev); this can be accomplished by using uranium-238 or thorium, rather than uranium-235 or plutonium.

Radioactivity.—Many nuclear reactions produced by neutrons lead to radioactive nuclei. These can be observed after the end of the irradiation with neutrons, a fact which is often an advantage. For the detection of fast neutrons, reactions are preferable which can be produced only by fast neutrons. The reaction $n + Al^{27} = Mg^{27} + p$ is a good example; Mg^{27} is a radioactive nucleus emitting beta rays with a lifetime of about 10 min. The reaction can be produced only by neutrons of more than 2 Mev kinetic energy and increases in probability with increasing neutron energy. Similar threshold detectors can be obtained by using magnesium, silicon, phosphorus, etc.

Of particular interest are threshold detectors sensitive to neutrons of extremely high energy. Such detectors are provided by nuclear reactions in which one neutron enters the nucleus and two neutrons are ejected. A useful reaction of this $(n,2n)$ type occurs with copper, leading to the formation of the radioactive nucleus Cu^{62} of 10 min. half life; it occurs with neutrons of more than about 11 Mev energy. For still higher neutron energy carbon is a good detector; a reaction of the same type leads to the formation of C^{11}, a radioactive nucleus of 20 min. half life. The minimum neutron energy required in this case is about 20 Mev.

Detectors for Slow Neutrons.—The recoil type detector is not usable in this case, which leaves only two types:

Nuclear Reactions.—The most generally useful detector of slow neutrons is based on the (n,α) reaction $n + B^{10} = Li^7 + He^4$. This reaction has an extremely high probability for slow neutrons (cross section, 4,000 barns). The alpha particles have an energy of about 1.5 Mev and are easily observed. The most commonly used detector consists of an ionization chamber filled with boron trifluoride gas; the ionization pulses are detected with the help of a linear amplifier. Moderate size chambers of this type (about 10 cm. long) at atmospheric pressure will detect about 10% of the neutrons of thermal velocity (2 km. per second) incident upon them. Increase in the pressure and size, and enrichment of the boron trifluoride by boron-10, will increase the efficiency. The detection of slow neutrons is much more efficient than the detection of fast ones.

Boron can also be used in the form of thin foils of boron metal or boron carbide, the alpha particles being detected in some neutral gas.

Fission is a very convenient means of detecting slow neutrons because of the large pulses of ionization from the fission fragments. Uranium-235, uranium-233 or plutonium must be used because only these nuclei undergo fission when bombarded with slow neutrons.

Radioactivity.—There are many ways of observing slow neutrons by using the formation of radioactive nuclei. The most useful type of nuclear reaction for this purpose is the simple capture of neutrons (with emission of gamma rays), which is generally much more probable for slow neutrons than for fast ones and thus provides a specific detector for slow neutrons. As has been mentioned before, neutron capture leads often, although not always, to the formation of a radioactive nucleus. Indium foils have been found especially useful as detectors of slow neutrons, but also silver, gold, rhodium, bromine, iodine and other substances have been used successfully. The radioactivity is observed promptly after the irradiation by neutrons.

By making use of the resonance capture of neutrons, detectors of this type can be selected so as to indicate slow neutrons of fairly definite velocities. For example, the number of thermal neutrons (very slow, with energies less than 0.4 ev) can be measured by utilizing the fact that cadmium absorbs these neutrons very strongly while it is transparent for neutrons of higher energies. If the resultant radioactivity is measured, for instance, in an indium foil with and without a surrounding shield of cadmium, the difference will indicate the number of thermal neutrons incident upon the foil. On the other hand, the radioactivity observed with the foil shielded by cadmium is almost entirely the result of neutrons whose kinetic energy corresponds to a resonance in the indium nucleus (see *Capture of Neutrons*, above). Thus, the properties of neutrons of various energies can be observed by using detectors with different resonance energies.

Neutron Diffusion.—*Thermal Neutrons.*—Neutrons cannot be accelerated—they must be accepted with whatever energy they have upon formation—but they can be retarded. This can be done by permitting the neutrons to collide with nuclei; in each collision some kinetic energy is transferred from the neutron to the

nucleus according to the equation given above. If this process is continued for a sufficient number of collisions, the velocity of the neutrons will be reduced until they come into equilibrium with the thermal motion of the atoms with which they collide.

In this manner so-called thermal neutrons are produced. The thermal neutrons have a velocity distribution similar to that of molecules in a gas; their mean energy at room temperature is about 0.025 ev. The thermal neutrons continue to make collisions with atomic nuclei, but since they are now in thermal equilibrium, these collisions no longer slow the neutrons down, there being equally many collisions in which the neutron gains and in which it loses energy. Ultimately, the neutron will be captured by a nucleus.

The production of slow neutrons, and of thermal neutrons in particular, is important from the scientific as well as from the practical point of view. The investigation of thermal neutrons has yielded most of the information about the radioactive nuclei formed by neutron capture. The investigation of neutrons of somewhat higher energy showed the existence of resonance levels in nuclei and thus laid the foundation for the modern theory of the compound nucleus (see *Capture of Neutrons*, above). For nuclear reactors in which natural uranium is used, slow neutrons are important in order that the fission of uranium-235 may predominate over the capture of neutrons in uranium-238. Whatever the purpose of the slowing down, it is important that not many neutrons are lost by capture during the process.

The most commonly used moderator for the slowing of neutrons is hydrogen in the form of paraffin or of water. Hydrogen has the advantage that the neutron loses a large fraction of its energy in each collision (see *Fast Neutron Detectors*, above) and that the effective cross section is large. Neutrons of an initial energy of 2 Mev become thermal at an average distance of about 10 cm. from the source, in paraffin or water. This corresponds to about 18 collisions per neutron with protons. However, a paraffin block of at least 50 cm. radius is required to prevent a sizable fraction of the neutrons from escaping. If the neutrons are emitted from the source with higher kinetic energy, larger amounts of paraffin are needed to slow them down and vice versa.

For nuclear reactors or piles, hydrogen-containing substances are not suitable because protons capture neutrons with considerable probability. In this case, either heavy water or graphite is commonly used. The energy transfer in a collision is in this case much less than in the case of protons, and the effective cross sections are also smaller. Therefore, much larger amounts of material are required to slow the neutrons down to thermal energy; this is one of the reasons for the large size of graphite-moderated reactors. Heavy-water reactors are much more compact, and ordinary water can be used if slightly enriched uranium is present. On the other hand, there is practically no capture in either graphite or heavy water until the neutrons have been slowed to thermal energy, and even at thermal energy they will make hundreds of collisions before being captured.

The mathematical treatment of neutron diffusion is usually done in two stages; namely, first the slowing down to thermal energy and then the diffusion of the thermal neutrons. The second stage can be treated according to the ordinary methods of diffusion theory, using the diffusion equation

$$\tfrac{1}{3}\, lv\nabla^2 n - \frac{n}{\tau} + q = 0$$

where n is the density of neutrons (number per cubic centimetre), q the strength of the neutron source (number produced per cubic centimetre per second), l is the mean free path of the neutrons between two collisions, v their mean velocity and τ their mean lifetime, that is, the mean time which elapses before they are captured.

The mathematical treatment of the first stage, the slowing process, is quite difficult because the mean free path of the neutron changes with its velocity. A very useful although not exact concept in this theory is the age of the neutron, defined as one-sixth of the mean square distance traveled by the neutrons from the source to the point at which their energy drops below a certain arbitrary energy, E. The age η can be calculated as a function of E from experimental data, and the density of neutrons of energy E at the distance r from the source in a homogeneous medium is given approximately by

$$n(\eta,r) = (4\pi\eta)^{-3/2} \exp^{-r^2/4\eta}$$

Nuclear Energy.—Neutrons supplied the key for the release of nuclear energy. Fission of uranium can be caused by neutrons, and in each fission a certain number of neutrons, ν, are released. For uranium-235, for example, ν, has the value 2.5. This is the basis of the nuclear chain reaction in which each of the neutrons produced in fission is again available to react with a uranium nucleus and can cause another fission.

Conditions are simplest in the rare isotope uranium-235, or in plutonium-239. These substances can be made to undergo fission by neutrons of any velocity; in fact, slow neutrons are most effective. In a large mass of uranium-235, every neutron which has been released in a fission may in turn cause fission. Since the number of neutrons released in each fission is about 2.5, the total number of neutrons will increase in this process. The increase is rapid because very little time elapses between the production of a neutron and its fissioning of another nucleus. With large amounts of uranium-235 or plutonium, therefore, the result is a veritable avalanche of neutrons and an explosive release of fission energy. This is the principle of the fission bomb.

If the amount of uranium-235 is reduced, a fraction of the neutrons produced in it will escape. If the amount of uranium is made small enough, so that only one neutron out of every ν neutrons produced will stay in the uranium, whereas the remaining $\nu - 1$ escape, the reaction will cease to lead to a multiplication of the number of neutrons but will merely be self-sustaining. This is the principle of the power reactors, which in the 1960s were operating in numerous power plants as well as in ocean vessels and submarines. It is ordinarily desirable to keep the amount of the expensive material, uranium-235 or plutonium, to a minimum. This is accomplished both in the controlled reactor and in the bomb by surrounding the active material with a reflector, *i.e.*, any substance which can scatter neutrons back to the active material, and thus minimize the number of escaping neutrons. Conditions are somewhat more complicated if ordinary uranium is used instead of the separated isotope 235. In this case the abundant isotope of uranium, 238, undergoes fission only when bombarded by fast neutrons, whereas slower neutrons are simply captured, leading to the formation of uranium-239. In this capture the incident neutron disappears and no new neutron is emitted. Only the rare isotope uranium-235, which comprises about 0.7% of natural uranium, undergoes fission with slow neutrons, and thus can keep the chain reaction going. But in general the fission in 235 is much weaker than the capture in 238; only for neutrons of very low velocity, less than 1 ev, is the ratio reversed. Since it is not possible to avoid nuclear collisions and thus keep the neutrons at very high energies (at which they could produce fission in 238), it is necessary to slow them down completely, *i.e.*, to energies less than 1 ev, so that they can cause fission in 235 with high probability.

On the basis of these considerations atomic energy reactors are designed to include a moderator, usually graphite or heavy water (see *Neutron Diffusion*, above), which serves to slow the neutrons down to thermal energies. The neutrons produced by fission have kinetic energies of several million electron volts; they are then permitted to diffuse in the moderator and come back as thermal neutrons to the uranium. Then some of them will cause fission in 235 and thus produce new neutrons to sustain the chain reaction. Other neutrons returning to the uranium will be captured in 238 and produce uranium-239. This is a radioactive nucleus which decays successively by β emission into neptunium and then into plutonium-239. The plutonium can be separated chemically from the uranium and can be used in its turn for nuclear energy production. The production of plutonium in a chain-reacting pile is the first instance in which one chemical element has been transmuted into another in large quantities by man. Plutonium is fissionable by slow neutrons. In the so-called breeder reactor,

plutonium is created from uranium-238 as the reactor generates power from the fission of uranium-235. Thus the very operation of producing power also can be used to produce new fissionable fuel.

These reactors are very useful for the production of neutrons in large quantity. By letting the emerging neutrons diffuse through large additional amounts of moderator, it is possible to obtain thermal neutrons which are almost entirely free of fast neutrons. A great variety of radioactive nuclei, useful as tracers in biology, chemistry and for industrial research, may be produced by introducing samples into nuclear reactors where they are exposed to intense flux of neutrons and become radioactive by neutron capture.

NEUVE CHAPELLE, BATTLE OF (1915), the first British offensive against the Germans after the advent of trench warfare on the western front in World War I (*q.v.*). After the French offensive in Champagne during the winter of 1914–15 had failed, the British commander in chief, Field Marshal Sir John French, planned an offensive in the Pas-de-Calais area with the initial object of seizing the village of Neuve Chapelle and the hope of piercing the German defenses and capturing Lille. Two British divisions (7th and 8th) and two Indian (Lahore and Meerut), under the command of Gen. Sir Douglas Haig, were involved. On March 10, 1915, after a 35-minute bombardment, the attack began on a narrow front. Some initial success was achieved and the troops entered the village. The Germans then counterattacked successfully while the British ran out of gun ammunition. When, late on March 12, the offensive was stopped, an advance of about 2,000 yd. on a front of 1,000 yd. had been made. British casualties were about 11,600 and German casualties were about the same. Useful lessons were learned, including the necessity for much heavier artillery bombardments in trench warfare, and the futility of launching infantry against uncut barbed wire. (C. N. B.)

NEUWIED, a town of Germany, *Land* (state) of Rhineland-Palatinate, which after partition of the nation following World War II became part of the Federal Republic of Germany, is situated on the right bank of the Rhine near the Wied stream, 17 km. (10 mi.) N.W. of Coblenz by road. Pop. (1961) 26,359. The town incorporates the ancient village of Heddesdorf, and buildings include the 18th-century baroque château of the Prince of Wied, churches of several denominations and 17th- and 18th-century houses. The former Moravian school (1756–1910) was attended by 2,720 British boys. Neuwied is on the Frankfurt am Main-Cologne railway, and is a highway junction. There are quays for passengers and freight. The town has a handsome dike wall and a steel road bridge across the Rhine. Industries include iron and steel production, engineering, and the manufacture of veneer, paper, chemicals, and pumice building materials made from the local volcanic sand. Neuwied was founded as a refuge for victims of religious intolerance by Count Frederick of Wied in 1653, and in the 18th century became a flourishing commercial and craftsmen's town. Roman *castra* were excavated at Heddesdorf and at Niederbieber nearby. (A. MT.)

NEVA, a river of Leningrad *oblast* in the Russian Soviet Federated Socialist Republic of the U.S.S.R., is the outlet for Lake Ladoga (*q.v.*) and flows into the head of the Gulf of Finland by way of a delta. The river is only 74 km. (46 mi.) long, but its drainage basin covers about 109,000 sq.mi., and includes lakes Ladoga, Onega and Ilmen and the Svir and Volkhov rivers. Its average annual discharge is 89,699 cu.ft. per second. Its banks are low and although its lower course is enclosed in stone embankments the spring floods are occasionally troublesome to the city of Leningrad; the highest recorded, in 1924, reached 16½ ft. Freeze-up begins about mid-November and is complete by the beginning of December. The thaw comes in the second half of April. The Neva is historically one of the most important rivers in Russia. In Kievan times it was the northern end of the "water road" via the Volkhov and Dnieper to the Black sea and Byzantium. Later the Swedes established two fortresses, Noteborg (Petrokrepost) at the Ladoga outlet and Nyenschanz (Nienshants) at the confluence of the Okhta, a small right-bank tributary, within present-day Leningrad. Peter I (the Great), after capturing these in 1703 founded St. Petersburg on the delta and made it his capital. As Leningrad, it is the second town and first port of the U.S.S.R. The Neva is navigable by ocean-going ships and forms part of the White sea–Baltic waterway (*q.v.*) and the Volga–Baltic waterway. (R. A. F.)

NEVADA, popularly known as the "Sagebrush state," or the "Silver state," is one of the far western states of the U.S., admitted to the union on Oct. 31, 1864, as the 36th state. It is bounded north by Oregon and Idaho, east by Utah and Arizona, south and west by California. The Colorado river, separating it in part from Arizona, is the only natural boundary the state possesses, the others being arbitrary lines of geodetic measurement. Nevada ranks seventh among the states in size, having an area of 109,788 sq.mi., 752 sq.mi. of which are water surface. Its extreme length north and south is 483 mi., and its extreme width east and west is 320 mi. Its name, a Spanish word meaning "snow clad" was originally applied to the snow-capped Sierra Nevada on the Pacific slope. The capital is Carson City. The state motto is "All for Our Country." The state flower is the sagebrush, the state tree the single-leaf piñon. The state flag is of solid cobalt blue, with, in the upper left quarter, crossed sprays of sagebrush surmounted by a scroll bearing the words "Battle Born" and by a single silver star.

PHYSICAL GEOGRAPHY

Physical Features.—With the exception of its northeast and southeast corners, the state (between approximately latitude 35° and 42° N. and longitude 114° 2′ and 120° W.) lies wholly within the Great Basin, the floor of which is really a vast tableland between 4,000 and 5,000 ft. above the sea. This plateau, however, is not a plain, but contains many buttes, mesas and isolated mountain ranges, the latter running generally in a north–south direction and rising 1,000 to 7,000 ft. above the level of the plain. These ranges are from 5 to 20 mi. wide at their bases, and the valleys between are of about the same width. The total area of the valleys is about equal to that of mountainous land.

In the northeast an unnamed range of highlands, broken and ill-defined, with a general east–west trend, forms the water parting between tributaries of the Humboldt river in the Great Basin region and those rivers that flow to the Snake river in Idaho and Oregon and from there via the Columbia to the Pacific ocean. The drainage area of the Snake amounts to about 5,000 sq.mi., the Owyhee, Little Owyhee and Bruneau rivers and Salmon Falls creek being the principal streams. In the southeast corner is the third drainage system. There the Virgin river from Utah, after crossing the northwest corner of Arizona, enters the state and flows southwest for 60 mi. until it joins the Colorado river. The latter stream flows for 150 mi. along the southeastern boundary toward the Gulf of California.

The Colorado leaves Nevada at an altitude of only 470 ft. above sea level, the lowest point in the state. The mean elevation of the state is 5,500 ft. and, with the exception of the dip to the Colorado in the southeast, all of it lies above the 2,000-ft. line.

The Sierra Nevada, which forms the western rim of the basin, sends into the state a single lofty spur, the Washoe mountains. At the foot of this range there is, relatively speaking, a depression, with an altitude of about 3,850 ft. above the sea, which receives the drainage of the eastern slopes of the Sierra and what little drainage there is in the northern half of Nevada. From this depression eastward the general level of the plateau rises to an elevation of 6,000 ft. near the eastern borders of the state.

The mountain ranges also increase in height and importance as far as the East Humboldt range, a lofty mass about 60 mi. W. of the Utah boundary. This range is the water parting for nearly all the westward-flowing streams of the state, and is by far the steepest and most rugged within Nevada, a number of its peaks attaining a height of more than 8,000 ft. On its eastern slope the waters soon disappear within the bed of narrow canyons, but break out again at the foot in ice-cold springs that form the source of the Ruby and Franklin lakes; on its western side the descent is more gentle, and the waters form the south fork of the Humboldt river. The two highest mountain peaks in the state are Boundary peak of the White mountains in Esmeralda county (13,145 ft.) and Wheeler peak of the Snake range in White Pine county (13,061 ft.).

The Humboldt is the most important of the basin streams. Rising in the northeast it flows in a tortuous channel in a general southwesterly direction for 290 mi. and drains 7,000 or 8,000 sq.mi. It empties into Humboldt lake, the overflow from which goes into the so-called Carson sink. At no part of its course is the Humboldt a large river, and near its mouth its waters are subalkaline. The Truckee, Carson and Walker rivers flow with more vigour, receiving their waters from the eastern slopes of the Sierra Nevada and discharging them into alkaline lakes. Of these lakes Pyramid is the largest, being about 30 mi. long and 4 to 13 mi. wide. Walker lake is 33 mi. long but only six or seven miles in width. These larger lakes always contain water, varying only in area and depth, but the smaller lakes usually evaporate in the course of the summer. The latter are formed by waters that fall on barren mountainsides and rush down in torrents, forming in the valleys shallow bodies of water yellow with mud held in suspension.

Climate.—The skies of Nevada are clear nearly every day in the year. The mean annual precipitation varies from 3 in. in the southwest (Esmeralda county) to 12 in. in the east (White Pine county), and varies also according to altitude. Snow rarely lies on the ground in the valleys. Prevailing winds are from the south, southwest and west.

Soil.—There are three general types of soil in Nevada. Gray desert soils are found in the arid low country and on the low slopes going up into the mountains. The mountains, generally arid or semiarid, have various mountain varieties of soils. Alluvial soils are found along the rivers.

Vegetation.—Except for the alkali flats no portion of the desert is devoid of vegetation, even in the driest seasons. In the Washoe mountains there is a heavy growth of conifers extending down into the valleys, but in many places these mountains have been almost deforested to provide timber for the mines. In other places these areas have been incorporated into national forests, in the endeavour to protect and foster the growth of timber and vegetation so as to regulate the drainage of the state. On all but the lowest ranges of the basin the piñon and juniper are found, but these rarely grow to a height of more than 15 ft., on the principal ranges above 6,800 ft. is the stunted mountain mahogany (*Cerocarpus* species). But except for these infrequent wooded areas, the mountains are even more bare than the valleys, because their shrubs are dwarfed from exposure. The valleys are covered with typical desert shrubs, greasewood, creosote bushes and sagebrush, and with bunch grass, which is valuable for grazing. The three-dented leaf sagebrush (*Artemisia tridentata*) is the commonest of the many species of sagebrush, growing sometimes to a height of ten feet with a silvery green leaf and yellow flower stalk. The creosote bush (*Covillea tridentata*), typical of the vegetation of the southern part of the state, has conspicuous yellow flowers. About 30 species of cacti are found in Nevada, and a number of yuccas, most conspicuous of which is the Joshua tree (*Yucca brevifolia*), which may reach a height of 40 ft.

Animal Life.—Deer are very common in Nevada, along with certain predatory animals such as the coyote, badger and bobcat. Among the rodents, several varieties of jack rabbits and many types of ground squirrels and desert mice and rats are prevalent in the desert country. The magpie and western varieties of sparrows are common, while the golden eagle is found sparingly in the state.

Parks and Recreation.—Nevada has many scenic attractions, many of them, such as the Death Valley National monument (115,240 ac. in Nevada) and the Black Rock desert, in the desert country. The Lehman caves, a limestone cavern, is 68 mi. S.E. of Ely and the Jarbridge canyon is in northern Elko county. The Valley of Fire, 50 mi. N.E. of Las Vegas, has thousands of prehistoric Indian drawings and fragments of petrified forest intermixed with red sandstone. Cathedral gorge in Lincoln county has been called a Bryce canyon in miniature. Hoover dam is 30 mi. from Las Vegas. Lake Mead, created by the dam and one of the largest man-made lakes in the world, provides year-round fishing and water sports. Walker and Pyramid lakes (remnants of the prehistoric Lahontan lake) are scenic and sporting attractions. Lake Tahoe lies across the California-Nevada boundary and its beaches attract many sports enthusiasts.

The state also has several excellent winter sports areas, largely in the Sierra Nevada. Reno is the central point for the ski country of the Sierras, but other ski resorts are found in the Ruby mountains near Elko, the Ward mountains near Ely and the Charleston park area 35 mi. N.W. of Las Vegas.

HISTORY

The first recorded person of European descent to enter the limits of Nevada was Francisco Garcés of the Order of St. Francis, who set out from Sonora in 1775 and passed through what is now the extreme southern corner of the state on his way to California. Half a century later trappers of the Hudson's Bay company led by Peter Skene Ogden entered Nevada from the north and discovered the Humboldt river. In 1827 Jedediah Smith, an American trader from St. Louis, crossed the state from west to east on his return from California after the first recorded journey from the Mississippi to the Pacific by the central route. In 1833 Capt. Benjamin Bonneville's men were on the Humboldt, and during 1843–45 John C. Frémont made a series of explorations in the region.

The first recorded emigrant train to California crossed the state in 1841.

Territorial Period.—By the treaty of Guadalupe Hidalgo, negotiated in 1848 at the close of the war with Mexico, Nevada became U.S. territory. It was then a part of California known as the Washoe country and so remained until 1850, when most of the present state was included in the newly organized territory of Utah (*q.v.*). One of the first settlements was made in 1849 by Mormons at Genoa in the valley of the Carson river. There in 1851 the earliest recorded public meeting in the state was held to frame a government for the settlers since the seat of the territorial government of Utah was considered too remote to afford protection to life and property. But the Utah authorities intervened, and in 1854 the Utah legislature created the county of Carson to include all settlements in western Utah.

In 1858 Carson City (*q.v.*) was laid out, and in the following year the people of Carson county chose delegates to a constitutional convention which met at Genoa and drafted a constitution. It was adopted by vote of the people, but this attempt to create a new state government proved abortive, and it was not until the mineral wealth of the Washoe country became generally known that congress took action.

In 1861 the territory of Utah was divided at 39° W. of Washington, D.C., and the western portion was called Nevada. The Comstock lode, one of the richest deposits of precious metal known in the world, was discovered in 1859, and Nevada ceased to be merely a highway for gold seekers on the way to California and became a stopping place. Virginia City became the most famous of all the mining camps of the far west (*see* VIRGINIA CITY).

Statehood.—An attempt to win statehood in 1863 was defeated, but in 1864 when it became evident that two more votes might be needed in the U.S. senate to propose the 13th amendment, party leaders at Washington urged the people of Nevada to adopt a constitution and enter the union as a patriotic duty. The third constitutional convention met at Carson City and drew up a constitution which was duly ratified and in October of that year, Pres. Abraham Lincoln proclaimed the new state. The eastern bound-

ary was pushed eastward to its present location on the 37th meridian west of Washington, D.C., in 1866; the southern boundary also was fixed in that year.

Nevada territory had been loyal to the union throughout the American Civil War. In spite of its scanty population, in 1861 it furnished a company of troops that was joined to a California regiment. In 1863 the territory raised six companies of infantry and six of cavalry (about 1,000 men), which saw no actual service against the Confederates but were useful in subduing hostile Indians.

The history of the state for many years after its organization was largely a history of its mines. From 1864 to 1868 there was a general reaction in the industry caused by unwarranted speculation and inflated values. After 1868 there came a period of consolidation, of more systematic workings, and of deeper development. In 1873 came the discovery of the "big bonanza" by John Mackay, James Fair, William O'Brien and James C. Flood, who became the four "bonanza kings" of Nevada. In 1873, $21,000,000 was taken from the Comstock and production increased until a maximum of $36,000,000 was reached in 1878. The Sutro tunnel intersected the lode in the latter year and drained the mines. But the richer workings soon proved below the tunnel level and the shafts were sent deeper. In 1882 an immense flow of hot water was struck which flooded the principal mines up to the Sutro tunnel level. The miners were forced to return to the upper levels and work the lower-grade ores. Production decreased, and with the end in sight the market slumped. Also, the national government had abandoned its artificial maintenance of the price of silver.

The period of depression lasted until about 1900 when the discovery of a new mineral belt in southern Nevada brought renewed prosperity. Tonopah, 60 mi. from the railroad, became the new Mecca. Fast upon the heels of the Tonopah discovery came that at Goldfield (*q.v.*). A railway was completed to the new camps in 1904, and Tonopah proved to be one of the largest and steadiest producing districts of the state. Copper ores of vast extent were discovered at Ely at about the same time, and the Nevada Northern railway was completed to this camp in 1907.

The depression immediately before 1900 turned attention to the agricultural and livestock possibilities of the state. Accessibility of markets through improved rail and highway transportation facilities aided in the expansion of the livestock industry. The river valleys under irrigation proved most fertile, and these were soon settled by large-scale ranchers. On the river bottoms the ranchers raised their hay and controlled a still larger acreage of the upland grazing ground. Private irrigation systems were supplemented by federal undertakings, the most notable being the Truckee-Carson project. The prosperity of many beautiful valley towns came to be founded on the permanent basis of agriculture rather than the uncertain one of mining.

Until the silver agitation of the 1890s Nevada was safely Republican. The state's politics in the early period were highly corrupt, and many rich mine owners were accused of buying their seats in the United States senate. For four state elections the Silver party of Nevada swept the state. After the issue subsided the old parties came into control.

After the legalization of gambling in 1931 and the reduction to six weeks of the residence requirement for divorce, Nevada became a marriage, divorce and resort centre. The principal resort areas are Las Vegas, Reno (*qq.v.*) and Lake Tahoe. Las Vegas attracts most of its tourists from the Los Angeles area, and it is famous for its resort hotels and gambling casinos. Reno draws many pleasure seekers from the San Francisco bay area. The gambling tax is second only to the sales tax in revenue from taxation for the state. Nevada's liberal divorce laws attract people from all parts of the country; because of the no-waiting period for marriages, however, many more weddings than divorces are performed in the state.

In the post-World War II years, Yucca Flats near Las Vegas became a primary atomic testing ground. Another atomic test site was developed near Fallon. The introduction of Bonneville hydroelectric power and construction of a pipeline to bring natural gas into northwestern Nevada promoted industrial development.

GOVERNMENT

Nevada is governed under its original constitution, adopted in 1864 and since amended in important respects. The usual method of amendment is the passage of a proposal by a majority of both houses of two consecutive legislatures followed by popular approval at a general election. In the 1958 election, for the first time in the history of the state, an amendment proposed by initiative petition was passed by the people.

Executive.—The principal executive officers of the state are the governor, lieutenant governor, secretary of state, attorney general, controller and treasurer, all elected for four-year terms. The governor possesses a limited pardoning power in that he must have the support of two other members of the Pardons and Parole board (the three justices of the supreme court and the attorney general). Reorganization of the executive department by the legislature in 1963 merged 16 formerly separate agencies and established a new department of administration, a department of commerce and a combined department of health and welfare including supervision of child and youth services and institutions. The state park system was placed in the department of conservation and natural resources.

Legislative.—The legislature, composed of a senate and assembly, meets in regular session in January of odd-numbered years. There is no constitutional limit on the length of a regular or special session, but salaries of legislators cease after 60 and 20 days, respectively. The constitution requires the number of assemblymen (apportioned according to population, with each county having at least one) shall not be less than twice nor more than three times the number of senators (each county having one). With the overwhelming majority of the population of the state concentrated in two counties (Clark and Washoe), the rural areas have been traditionally over-represented in the legislature. Senators are elected for four years, approximately one-half the membership retiring every two years; the entire assembly is elected biennially. Nevada joined in the Populist movement for more direct control of the government by the people in adopting the referendum in 1904 and initiative and recall in 1912.

Judiciary.—The supreme court consists of a chief justice and two associate justices elected for six-year staggered terms. The number of district courts and judges (elected for four-year terms) is determined by the legislature. The great number of divorce cases made it necessary to expand the number of district judges who sit in Las Vegas and Reno. Each township has a justice of the peace who is elected for a two-year term.

Finance.—The state legislature authorizes all expenditures, and in turn fixes a tax levy which is intended to produce revenue enough to meet these expenditures. The supervision of the assessment and collection of taxes is in the hands of the Nevada tax commission, consisting of the governor, acting as chairman, and six commissioners appointed by him. The director of the budget prepares the annual state budget and exercises control of departmental spending. The director and the state board of examiners scrutinize every expenditure item. The post audit function is performed by the legislative auditor responsible to the legislature and the legislative counsel bureau.

The major sources of tax income to the state are general sales tax, gambling tax, motor fuel taxes, motor vehicle licence taxes, cigarette tax and liquor tax. Almost all of the property tax is turned over to local units—schools, cities and counties. For the property tax there is a constitutional limit of $5 on each $100 valuation. Also, the state indebtedness cannot exceed 1% of the total assessed valuation of property in the state.

POPULATION

The population of Nevada in 1860 was 6,857; in 1880 it was 62,266 (as a result of the ore discoveries); in 1910, 81,875; in 1940, 110,247; in 1950, 160,083; and in 1960, 285,278. This last figure represented an increase of 78.2% over the 1950 population. The population per square mile in 1960 was 2.6, as compared with 1.5 in 1950 and 49.6 for the U.S. in 1960. Of the 1960 population, 200,704 or 70.4%, lived in incorporated places of 2,500 or more as compared with 52.5% in 1950 and 39.3% in 1940.

Reno	51,470	32,497	21,317	12,016	4,500
Sparks	16,618	8,203	5,318	3,238	—

*Populations are reported as constituted at date of each census. Note: Dash indicates place did not exist during reported census, or data not available.

The state has two standard metropolitan statistical areas, which are Las Vegas and Reno. These areas had a total population of 211,759 or 74.2% of the total population of the state in 1960.

The number of occupied dwelling units (or households) in 1960 was 102,694, as compared with 56,515 in 1950. The average population per household had declined from 3.09 in 1940 to 3.05 in 1950 and to 3.02 in 1960.

The population of the state was distributed by colour and nativity in 1960 as follows: 88.1% native white; 4.3% foreign-born white; and 7.6% nonwhite, mainly Indians. There were 106.7 males per 100 females in the native white population and 116.7 in the foreign-born. Six and four tenths per cent of the population was 65 years old or over; 63.0% of the population 14 years old and over was in the labour force. Of the total number of employed males, 6.1% was engaged in agriculture, 3.7% in mining, 12.4% in construction, 8.0% in manufacturing, 6.1% in transportation and 16.8% in wholesale and retail trade.

There are 14 Indian reservations, in addition to several Indian colonies, in the state. The two dominant tribes are Paiute and Shoshone (*qq.v.*).

EDUCATION

The state board of education is composed of eight lay members. Six of these are elected—one from each of the six educational supervision districts of the state—and two members are appointed by the elected members. The board appoints a superintendent of public instruction who is the executive head of the state department of education. The superintendent has no fixed term, serving at the pleasure of the board. The school districts are coextensive with the counties, and the districts receive substantial grants from the state treasury, with the amount based on the number of pupils attending school in a particular district. School attendance is compulsory for children between the ages of 7 and 17.

The only institution of higher learning in the state is the University of Nevada, with the main branch situated in Reno and a southern division at Las Vegas. (The university was originally established at Elko in 1874 but was moved to a 60-ac. Reno campus in 1886.) The university is divided into the following colleges: agriculture, arts and sciences, business administration, education, engineering, mining engineering and a school of nursing, in addition to a graduate division. The extension division carries on an ambitious program of taking classes to various parts of the state.

The governing body of the university is a nine-man board of regents, with three members elected from Washoe county, three from Clark county and three from the 15 small-population counties. The board members serve four-year terms.

HEALTH, WELFARE AND CORRECTIONS

A state orphans' home is located at Carson City, a state hospital for mental diseases at Sparks and a home for male juvenile delinquents at Elko. The state penitentiary is at Carson City. The department of health and welfare is one of the most important in the state from the standpoint of expenditures of funds.

THE ECONOMY

Agriculture.—Nevada is the most arid state of the United States because the high Sierra Nevada interrupts the moisture-laden clouds from the Pacific. East of these mountains, the valleys, however rich their soils, are covered with sagebrush and appear like monotonous desert wastes, except where some stream annually overflows its banks to create natural meadows, or where the land has been cleared of sagebrush and artificially watered. Agriculture is dependent almost entirely upon irrigation.

Principal crops in Nevada are hay, barley, wheat, oats and corn. In the southern part of the state, hay and forage, wheat, tomato plants and barley are the principal crops, with berries, apples and other orchard fruits growing on both irrigated and unirrigated lands.

In this arid region livestock are a far more important source of farm income than are crops. Approximately 65% of the agricultural income of the state is derived from grazing sources, and in 14 of the 17 counties livestock raising and farming dominate over any other industry (with the exception of gambling in Washoe and Clark counties). The average sized ranch in mid-20th century was 3,428 ac., with the larger ranching operations found in Elko, Humboldt and Pershing counties in the north and in Eureka, Lander and White Pine counties in the central and eastern sections. Many Basque sheepherders have settled in White Pine and Humboldt counties.

Mining.—Nevada metal production reached a peak in 1917, when gold, silver, copper, lead and zinc were produced to the value of $54,424,580. The years 1918–21 were years of swift decline, the production in 1919 being less than half that of 1918, and that of 1921 only half that of 1919. There was an upward turn in 1923 and a steady rise from then through 1929. Then the depression of 1929 caused a sharp decline.

Gold and silver were first to recover from the depression because of the revaluation of the gold dollar and the passage of the Silver Purchase act in 1934. The production of both metals declined sharply, however, during World War II and continued relatively low. The production of copper was stimulated by defense needs during World War II and, after a brief post-war decline, far exceeded the 1917 level.

In the early post-World War II years, Nevada continued to be an outstanding producer of magnesite, manganese ore, diatomite, mercury, perlite, sulfur ore, fluorite, tungsten, antimony and gypsum. In the late 1950s the reduction of the federal government's price-support program and foreign competition resulted in a sharp drop in production which, however, remained above all pre-war highs.

Manufacturing.—Manufacturing is limited in scope and production. Leading industries in the state include lumber and wood products; stone, glass and clay products; chemicals, insecticides and allied products; gypsum board; and titanium sponge.

Transportation and Communication.—Nevada is crossed east and west by three main lines of railway, the Southern Pacific and the Western Pacific in the northern part and the Union Pacific system in the southern part. Branch lines connect the more important mining towns with these lines. Railway mileage in the state reached a peak in 1915 when it amounted to 2,332 mi.; by the early 1960s it had decreased to about 1,500 mi. There are about 4,500 mi. of road in the designated state highway system, mostly paved. Several airlines operate in the state. There are more than 20 radio and television stations, the majority being in the Reno and Las Vegas areas.

NEVAI, ALISHIR (1441–1501), Turkish poet and scholar, is the greatest representative of Chagatai Turkish literature. He was born in 1441 into an Uygur family in Herat, where his father

was a member of the court chancellery. The king of Khorasan took him under his protection and thus he met the leading poets and scholars of the day. Under Husain Bayqara, his school friend, who succeeded to the throne of Herat, Nevai held a number of offices, but the latter part of his life he devoted to poetry and scholarship. His poetry includes four *divans* (collections) belonging to different phases of his life, and five romances on conventional themes, inspired by the *Khamsa* of Nizami (*q.v.*). His main prose works are: *Muhakemet-ul-lugateyn*, a comparison of the Persian and Turkish languages; *Mecalis-un-nefais*, the first collection of biographical articles on Turkish poets; and *Mizan-ul-evzan*, a treatise on Turkish poetic art. His mastery of the eastern Turkish language both in poetry and prose was such that classical Chagatai came to be known as "the language of Nevai."

See A. Bombaci, *Storia della litteratura turca* (1956). (F. I.)

NEVERS, a town of central France, capital of the *département* of Nièvre, is situated 232 km. (144 mi.) S.S.E. of Paris by road on the right bank of the Loire river at the confluence of the Nièvre river. Pop. (1962) 38,716. In its historical development from the Roman Noviodunum through the middle ages into modern times as a district centre rooted in the life of the surrounding agricultural countryside, and enlarged by some modern development of manufacturing, Nevers is a typical French provincial town. It has been the seat of a bishopric since the 5th century, and was the capital of the duchy of Nivernais (*q.v.*). The cathedral of St. Cyr combines a Romanesque church and a later Gothic church. The church of St. Étienne is pure Romanesque. The palace of the counts (later dukes) of Nevers, now occupied by the law courts and an important ceramic museum, dates from the 15th and 16th centuries and is one of the great buildings of central France. The chapel of the St. Gildard convent contains the body of Saint Bernadette (*q.v.*) Soubirous, the visionary of Lourdes, who lived at Nevers from 1860 to 1879.

Nevers was formerly an important river port on the Loire. Its industries are chiefly concerned with engineering, including rolling stock and aircraft manufacture. (Ar. E. S.)

NEVILLE (Nevill), the name of an English baronial family which came to play an important part in 15th-century politics. Several branches of the family existed in the century following the Norman conquest, but their origin and interrelationship still remain uncertain on many points. The family of Neville of Essex, the first to become prominent, descended from Alan (de) Neville (d. 1178), a younger son of Geoffrey Neville, whose father, Gilbert, was a Lincolnshire landholder at the time of the Domesday survey (1086). Alan's grandson, Hugh Neville (d. 1234), emerged as a leading adviser and confidant of King John, whom he supported in the negotiations over Magna Carta. His kinsman, Ralph Neville, bishop of Chichester, was chancellor of England from 1226 to 1238. A later Hugh Neville (d. *c.* 1335) of Essex was summoned to parliament as a baron in 1311, but the male line of this branch came to an end with the death of his son, John, 2nd lord, in 1358, his estates having been sold to his comrade-in-arms, William de Bohun, earl of Northampton.

A more brilliant destiny awaited the Nevilles of Raby in the county of Durham. This branch of the family stemmed from the marriage of Isabel Neville, the heiress of a line descended from Gilbert (d. *c.* 1169), an elder son of the Geoffrey Neville mentioned above, to Robert FitzMaldred (d. 1242–48), a north country landowner whose grandfather had received a grant of the lordship of Staindrop in Durham from Henry I. Robert's son, Geoffrey (d. *c.* 1242), retained the paternal arms but usually employed his mother's surname, which became hereditary in later generations. By this time the Nevilles had already acquired their distinctive connection with Yorkshire and with Durham, where they had castles at Raby and Brancepeth, but as yet they were still barons of modest estate. Geoffrey's son, Robert (d. 1282) was a strong royalist in the baronial wars; his son, Robert (d. 1271), acquired by marriage the estates of the FitzRanulf family in north Yorkshire, including the lordship of Middleham; and his grandson, Ranulf (d. 1331) was summoned to parliament as a baron in 1295. Ranulf's eldest son, Robert Neville, sometimes known as "the Peacock of the North" was slain by the Douglases in a border fray in 1319, and the estates passed to his younger brother, Ralph (d. 1367), 2nd lord, who was active as warden of the marches, served in the Scottish wars, and was a commander at the English victory at Neville's Cross in Oct. 1346.

Ralph was succeeded by his son, John (d. 1388), as 3rd lord Neville of Raby. A supporter of the powerful John of Gaunt, duke of Lancaster, whose retainer he became in 1370, Neville served on the Scottish marches and in the French war, leading an unsuccessful expedition to Brittany in 1372, and in the same year he became steward of the king's household. This association with English reverses abroad and unpopular Lancastrian policies at home made him a target of criticism in the Good parliament of 1376. But he escaped lightly, the fines imposed on him being remitted by the parliament of 1377, and he was able to devote his considerable fortune to the building of Raby castle and the erection of the great Neville screen in Durham cathedral, where he was buried in 1388.

His association with the house of Lancaster was renewed by his son, Ralph Neville (d. 1425), 4th lord, who secured the hand of Joan Beaufort, daughter of John of Gaunt, as his second wife. This marriage proved of decisive importance in the advance of Neville fortunes, especially when Gaunt's son, Henry of Lancaster, usurped the throne as Henry IV in 1399. Ralph Neville was created earl of Westmorland in 1397, and enjoyed a flow of royal favour; and his wife's connection with the king, and Ralph's own vigorous loyalty, brought the earl and countess wealth, influence and social prestige, which in turn made possible an unparalleled series of brilliant marriages for their many children. The eldest son of this marriage, Richard Neville, was matched with Alice Montagu, heiress of Thomas, earl of Salisbury, and his parents successfully carried through a vast transfer of land whereby Raby Sheriff Hutton and Middleham, with the larger part of the ancestral family estates, were settled upon him and his heirs, to the disinheritance of Ralph's children by his first marriage (*see* Westmorland, Earls of). Heiresses were likewise secured for three younger sons, George, William and Edward, who became, in right of their wives, Lords Latimer, Fauconberg and Abergavenny. The fifth son, Robert Neville (d. 1457) was appointed bishop of Salisbury in 1427, and translated in 1438 to the great palatine see of Durham. Nor were their sisters less fortunate: Richard, duke of York, John, duke of Norfolk, Humphrey, duke of Buckingham and Henry, earl of Northumberland, each married a daughter of Ralph Neville and Joan Beaufort. By 1450 the peers in parliament included five of Ralph's sons, five sons-in-law, and several grandsons. When one of these last, Richard Neville (d. 1471), eldest son of Salisbury, obtained the earldom of Warwick by marriage to the Beauchamp heiress, the Neville connection had become immensely influential, and its support for the Yorkist cause proved decisive in establishing that dynasty on the throne.

Under Edward IV Neville power reached its apogee. Richard, earl of Warwick, was the king's principal adviser, his brother George Neville (d. 1476), was archbishop of York and chancellor and with another brother, John Neville, Marquess Montagu, and his uncle, William Neville, Baron Fauconberg and now also earl of Kent, as the king's chief commanders, the Nevilles virtually ruled England in Edward's early years. But the wayward ambition of Warwick the Kingmaker (*see* Warwick, Richard Neville, Earl of) brought about their downfall. Warwick and Montagu were killed at the battle of Barnet in 1471; George Neville lost his influence; and William Neville had died without heirs in 1463. Although Warwick's daughter, Anne, married Richard, duke of Gloucester, and became queen of England when he usurped the throne as Richard III, the greatest days of the Nevilles were now over. They were themselves the chief victims of the Wars of the Roses in which they played so large a part. The senior line of the family, the earls of Westmorland, survived until 1601. The Nevilles, Lords Latimer, became extinct in the direct male line in 1577. The Nevilles of Abergavenny have continued into modern times; George Neville (d. 1785), 17th lord, was created earl in 1784, and William Neville (d. 1915), 5th earl, was made marquess of Abergavenny in 1876. The present marquess is John Henry Guy (1914–).

NEVILLE'S CROSS, BATTLE OF. This battle, fought on Oct. 17, 1346, followed the invasion of England by the Scots under David II in an attempt to help the French by distracting Edward III from the siege of Calais. David encamped at Bearpark outside Durham. But the forces of northern England had been assembled nearby by William de la Zouche, archbishop of York, and the lords Percy, Neville, Umfraville and Mowbray. A disastrous dawn foray by Sir William Douglas brought the whole English army upon the Scottish encampment. Both sides were then arrayed in three divisions. When the Scots abstained from launching an attack, a body of English archers advanced to gall them into action. Neglecting the chance to disperse the archers by a cavalry charge, David ordered an advance that brought his first two divisions to awkward positions. Some hours of hard fighting ensued, the survivors of the first division under the earl of Moray falling back upon the second division commanded by David. The third Scottish division under Robert the Steward (afterward Robert II) and the earl of March took to flight. The remaining Scots concentrated around their wounded king who was eventually captured by John Coupland. The heavy Scots losses enabled the English to reoccupy most of southern Scotland and pursue the French war.

NEVIN, ETHELBERT WOODBRIDGE (1862–1901), U.S. composer of light songs and piano pieces. Born at Edgeworth, Pa., on Nov. 25, 1862, he studied in Boston, New York and Germany; in Berlin he was a pupil of Karl Klindworth and Hans von Bülow. He first appeared as a pianist in Pittsburgh (1886) and later gave concerts in Boston, Chicago, New York and other U.S. cities. His early songs on English and German texts were influenced by Schubert and Schumann. His later pieces were in a lighter style. They include "The Rosary" (1898) and "Mighty lak' a Rose" (1900), which achieved great popularity. His best-known piano piece was "Narcissus" (1891) from the *Water Scenes*. He died at New Haven, Conn., on Feb. 17, 1901.

His brother ARTHUR FINLEY NEVIN (1871–1943) was a pupil in Berlin of Klindworth and of E. Humperdinck and became a conductor at Memphis, Tenn. He did research work on the folk music of the Blackfoot Indians of Montana (1903–04) and used this music in his opera *Poia* (Berlin, 1910). His other works include the one-act opera *A Daughter of the Forest* (1918), orchestral suites, cantatas and chamber works.

See J. T. Howard, *Ethelbert Nevin* (1935); A. F. Nevin, "Two Summers Among the Blackfoot Indians of Montana" in *The Musical Quarterly* (April 1916). (N. SY.)

NEVIS, an island of the Lesser Antilles in the Caribbean sea, forms with the islands of St. Kitts and Anguilla the British colony of St. Kitts-Nevis. Area 36 sq.mi. (93 sq.km.). Pop. (1960) 12,762. Nevis lies at latitude 17° 14′ N. and longitude 62° 33′ W. and is separated from St. Kitts by a two-mile-wide channel. An almost circular volcanic island, it is conical in appearance, rising gradually to a height of 3,596 ft. (1,096 m.) at Nevis peak. Charlestown (pop. [1960] 2,850), the chief town and port, lies on the southwest coast; it was the birthplace of Alexander Hamilton (*q.v.*). Sea-island cotton is the main crop, supplemented by sugar cane. Discovered by Columbus in 1493, Nevis was first colonized by the English in 1628, and subsequently enjoyed great prosperity. It was attacked by the French and Spanish on several occasions, being finally restored to Britain in 1783.

NEVSEHIR, capital of an *il* (province) of the same name in interior Anatolia, Turkey, located to the south of Kizil Irmak river 45 mi. (72 km.) N. of Nigde. Pop. (1960) 17,662. It lies on the slopes of a dry valley formed by a tributary of the Kizil Irmak and is characterized by stone houses built of hard volcanic tuff.

NEVSEHIR IL (area 2,172 sq.mi.; pop. [1960] 187,398) occupies the central part of the Anatolian plateau. Its eastern section is noted for its curious, densely dissected landscape caused by intense erosion, with earth pyramids, cones, pillars and old rock dwellings, especially around Goreme and Urgup. The climate is dry continental with extremely severe winters. Chief economic activities are cereal and grape cultivation, and stock raising.

(N. TU.; S. ER.; E. TU.)

NEVUS: *see* SKIN, DISEASES OF.

NEWARK, DAVID LESLIE, LORD (1601–1682), Scottish general who commanded the royalist forces during the third phase of the English Civil War, was the fifth son of Patrick Leslie of Pitcairly, Fifeshire, commendator of Lindores, and Lady Jean Stuart, daughter of the earl of Orkney. He began his military career on the continent, returning to Scotland in 1640. He was major general under Alexander Leslie, earl of Leven, at the battle of Marston Moor (1644) and was then sent into the northwestern counties and besieged and took Carlisle. When, after the battle of Kilsyth, Scotland was at the mercy of the marquess of Montrose and his army, Leslie was recalled from England in 1645, and made lieutenant general of horse. He surprised and routed Montrose at Philiphaugh near Selkirk on Sept. 13, 1645. He was then declared lieutenant general of the forces. After a short period of service in England he returned to Scotland, and reduced several of the Highland clans.

In 1650 Leslie was sent against Montrose, whom he defeated and captured. He had earlier declined to join in the Engagement on behalf of Charles I, but he now agreed to support Charles II and was appointed to the chief command of the new army levied on Charles's behalf. The result, though disastrous, abundantly demonstrated Leslie's capacity as a soldier, for Oliver Cromwell proved no match for him until his movements were interfered with and his army reduced to indiscipline by the representatives of the Kirk party that accompanied his headquarters (*see* CIVIL WAR, ENGLISH). After his defeat at the battle of Dunbar (Sept. 3, 1650) Leslie fought a stubborn defensive campaign up to the crossing of the Forth by Cromwell, and then accompanied Charles to Worcester, where he was lieutenant general under the king. On the defeat of the royal army (Sept. 3, 1651) Leslie was committed to the Tower of London, where he remained till the Restoration in 1660. In 1661 he was created Lord Newark, and received a pension of £500 per annum. He died in 1682.

NEWARK, a city and port of entry in northeastern New Jersey, U.S., is located on the west bank of the Passaic river and Newark bay, 8 mi. W. of lower Manhattan (New York city); the seat of Essex county, Newark, which is part of the New York-Northeastern New Jersey standard consolidated area, had a population (1960) of 405,220. The Newark standard metropolitan statistical area, which includes Essex, Morris and Union counties, had a population of 1,689,420. The city, which has 13 mi. of waterfront, is generally level but rises gradually from the Passaic river westward.

History.—Newark was founded in 1666 by Puritans who migrated from Connecticut under the leadership of Capt. Robert Treat. The settlement was established on land purchased from the Hackensack Indians for arms, ammunition, hoes, clothing, uniforms and liquor. The purchase included almost all of what is now Essex county and part of Union county. It was first named Pesayak Towne and later New Milford after Milford, Conn., from which some of the original settlers had come. The name was changed to Newark in honour of their pastor, Rev. Abraham Pierson (1608–1678), who came from Newark-on-Trent, Eng. Newark was chartered as a township in 1693 and incorporated as a city in 1836. For more than a century after its founding, Newark remained a quiet village of about 1,200 persons; then it experienced a sudden manufacturing and population expansion. Moses Combs, a local shoe cobbler, is credited with giving the industrial beginning to the town by starting its first shoe factory. Newark soon became a centre for leather tanning and shoe manufacture, and its industries included quarries, mills and iron foundries, as well as stagecoach and jewelry manufacturing. Its leading inventors were Seth Boyden, who developed the processes for making patent leather (1818) and malleable cast iron (1826); Rev. Hannibal Goodwin, who in 1887 patented a flexible film for motion pic-

tures and Edward Weston, who invented electrical measuring instruments.

Between 1850 and 1920 the city underwent rapid growth and expansion, its population increasing from 38,894 in 1850 to 414,524 in 1920. Between 1920 and 1930 the rate of increase fell off, and the next decade saw a slight drop in population (2.8%). This decline was mainly attributed to problems of urban blight that have plagued industrial centres and the resulting flight to the suburbs. During the 1940s, partially because of World War II, this tide was temporarily reversed and in the mid-1950s Newark experienced the beginnings of rejuvenation, with large-scale construction projects designed to stem urban blight. By 1960, however, the city's population had declined by nearly 8%, while its suburban population increased more than 24%. (For comparative population figures *see* table in NEW JERSEY: *Population.*) The proportion of Negroes increased from 17% in 1950 to over 50% in the 1960s. In July 1967 the National Guard helped to restore order after four days of looting and rioting in the Negro district.

Government.—Effective July 1, 1954, Newark had abandoned the commission form of government established in 1917 and adopted a charter form of the mayor-council type. Executive power is exercised by the mayor, administrative power is vested in an appointed business administrator and legislative power is exercised by the council.

Transportation, Commerce and Industry.—Newark has long been a centre for highway, rail, sea and air transportation and a major east coast distributing point for many of the nation's leading products. Both the Newark airport and the Port of Newark are operated by the Port of New York authority (*see* NEW YORK [CITY]: *Commerce and Industry*) as part of the great New York industrial and transportation complex.

The airport, one of the pioneer U.S. airports, was established in 1928 on a 2,200-ac. site three miles from the city's centre. Until the completion of La Guardia field in 1939, it was the principal air passenger terminal for New York city. The Port of Newark, started by the city in 1914 and later leased and operated by the Port of New York authority, has terminal and industrial facilities which make it one of the most efficient ports in the U.S.

Newark has long been noted for industrial diversification and concentration; its products include electrical equipment, chemicals, paints, malt liquors, bread products, processed meats, machinery, leather goods and jewelry. It is also a financial, retail, wholesale and insurance centre with a number of life, fire and casualty companies having their home offices in the city.

Education.—Located in Newark are the state-supported Newark College of Engineering (1881); Newark State college (public teachers, 1960); the Newark campus of Rutgers–the State university (*see* NEW JERSEY: *Education*); and a coeducational branch campus of Seton Hall university (Roman Catholic, 1856).

Parks and Recreation.—Near the centre of town is Military park used as a drill ground in colonial times and preserved as an oasis among the department stores and large office buildings. In the park is an imposing bronze group of figures, "The Wars of America," by Gutzon Borglum. To the north is Washington park, flanked by the public library, the Newark museum and several Rutgers university buildings. Branch Brook, a county park, is noted for one of the finest displays of Japanese cherry trees in the eastern United States. In front of the county courthouse, designed by Cass Gilbert, is Borglum's seated statue of Abraham Lincoln. Among churches of historic interest are Trinity Episcopal cathedral (1746), used as a hospital during the American Revolution; House of Prayer with its two-century-old stone rectory; and Old First Presbyterian church (1791). (S. N. W.)

NEWARK, a city of central Ohio, U.S., 33 mi. E. by N. of Columbus is the seat of Licking county. In pre-Columbian times the area was a cultural centre for the Mound Builders (*q.v.*). This is attested to by extensive, well-preserved earthworks to be seen in Moundbuilders and Octagon State parks. When first seen by Newark's settlers, these mounds were covered by dense forests containing trees more than 500 years old. The basic reason for the importance of this region to the Stone Age aborigines was the outcroppings of flint in the hills as at Flint Ridge State park nearby.

From its founding in 1801 by migrants from the middle Atlantic states, who settled at the forks of the Licking river, Newark was the trading centre for a prosperous agricultural region. Named for Newark, N.J., the home of an early settler, Newark was platted in 1802, incorporated in 1826 and chartered as a city in 1860. In 1825 the Ohio canal system was initiated at Licking Summit, 4 mi. S. of town and for a time the canal contributed greatly to the city's prosperity. The first railroad reached Newark in 1852, and by 1880 the population had grown to about 10,000, largely the result of industrial expansion. In mid-20th century leading industries included glass fabrication, aluminum processing, truck axles and transmissions, lawn mowers, corrugated boxes and other containers, plastics and petroleum products.

In Granville, 6 mi. E. of Newark, is Denison university (Baptist, 1831), a coeducational college. Buckeye lake is 10 mi. S. For comparative population figures *see* table in OHIO: *Population.* (W. T. U.)

NEWARK-ON-TRENT, a market town and municipal borough in the Newark parliamentary division of Nottinghamshire, Eng., 23 mi. N.E. of Nottingham. Pop. (1961) 24,651. It lies on the navigable arm of the Trent river and at the crossing of the Fosse way with the Great North road. Though Roman coins and pottery have been found nearby, there is no evidence of its having been a Roman settlement. Niweweorce ("the new work") was an important town in Saxon times. In 1055 Newark belonged to Lady Godiva who granted it to the monastery of Stow near Lincoln and it remained in the hands of the bishops of Lincoln until 1549, when it was incorporated.

A castle, probably wooden, and a bridge over the Trent were built by Bishop Alexander between 1123 and 1135, the castle being replaced by a stone building about 1173 by Geoffrey Plantagenet. Of this castle, where King John died in 1216, only the gatehouse and west tower stand; the other parts are remains of the rebuilding of about 1280. During the Civil War the castle was garrisoned for Charles I; it was besieged three times and Newark siege coins were minted there. On its surrender in 1646 a large part of it was destroyed by Cromwell. The cathedral-like parish church of St. Mary Magdalene is one of the finest in the country, its tower and spire being 246 ft. high. The crypt and four piers at the transept crossing are Norman; the lower part of the tower is Early English, the upper part and spire are Decorated; the nave dates from 1384–93 and the chancel from 1489. It contains one of the largest 14th-century brasses in the country and a fine 16th-century oak screen. An interesting monument in the town is the Beaumond cross (possibly 15th century) and among old brick buildings are the grammar and song school (founded in 1529), part of which contains the museum, and the 18th-century town hall in the marketplace.

The varied trades of Newark, which is the centre of an agricultural district, consist principally of brewing, malting, the quarrying of limestone and gypsum, the manufacture of ball and roller bearings, plaster and bricks, agricultural implements and beet sugar.

NEW BEDFORD, an industrial port of Massachusetts, U.S., 56 mi. S. of Boston at the mouth of the Acushnet river near Buzzards bay, is a port of entry and one of the seats of Bristol county. Pop. (1960) 102,477; standard metropolitan statistical area (New Bedford city and Acushnet, Dartmouth and Fairhaven towns in Bristol county; Marion and Mattapoisett towns in Plymouth county), 143,176. (For comparative population figures *see* table in MASSACHUSETTS: *Population.*)

Settled in 1652 by colonists from Plymouth who were joined in 1665 by Quakers from Rhode Island, there was no village on the site until 1760, at which time it was part of Dartmouth.

Bedford, as it was then known, assumed importance in 1765 when Joseph Rotch, a Nantucket merchant, built wharves and warehouses and expanded the village's infant whaling industry; in 1787 Bedford was set off from Dartmouth and incorporated as a town; it was chartered as a city in 1847. Fairhaven was separated in 1812. Originally named Bedford by Joseph Russell, one of the founders, in honour of his family's estates in England, it was later

changed to New Bedford to distinguish it from Bedford in Middlesex county. During the American Revolution the use of the harbour by American privateers led to an attack on Sept. 5, 1778, by the British under Earl Grey in which 70 ships were burned and the village almost completely destroyed by fire.

By 1820 New Bedford was the leading whaling port of the world, reaching its peak in 1857 with the registry of 329 whaling ships. From 1767 when the "Dartmouth," later one of the Boston Tea Party ships, slid down the ways, New Bedford was also an important shipbuilding centre. With the shifting of whale hunting grounds after 1791 from off Virginia and the Carolinas to the Pacific and after 1848 the arctic waters, the whaling industry began to decline. This decline was accelerated in 1859 by the discovery in Pennsylvania of petroleum, which displaced whale oil as an illuminant in oil lamps and as a lubricant for machinery.

The manufacture of fine cotton fabrics replaced whaling as the chief economic activity. From the founding of the first cotton mill in 1847 to the 1920s New Bedford was a leading textile centre. With the movement of the weaving industry to the southeast after the 1920s, apparel manufacturers moved into the vacated New Bedford mills and constituted the leading economic activity. There was, however, a trend toward diversification of industry with the manufacture of electrical equipment being the most notable development, although a wide variety of products including rubber goods, screws and bolts, twist drills, copper and brass goods and electrical machinery were manufactured.

The port business consisted of coal and petroleum products although over 75,000,000 lb. of fish were landed annually. New Bedford is in the heart of the southern New England resort area.

Local landmarks include Ft. Rodman built during the American Civil War on Clark's Point to guard the harbour, the Bourne Whaling museum and the Seamen's Bethel on Johnny Cake hill made famous in Herman Melville's *Moby Dick.* (I. T. S.)

NEW BERN, a city and port of entry in eastern North Carolina, U.S., is on the Neuse river at the mouth of the Trent, about 110 mi. S.S.E. of Raleigh; the seat of Craven county. Founded in 1710 by about 400 Swiss and Germans under the leadership of Christopher von Graffenried, of Bern, Switz., the settlement was nearly wiped out by Tuscarora Indian uprisings between 1711 and 1713. The town, however, the second to be established in North Carolina under the lords proprietors, was repopulated and incorporated in 1723.

North Carolina's first printing press (1749) and first tax-supported school (1764) were established there under royal government. The provincial assembly began meeting in New Bern in 1737 and the city's status as colonial capital of North Carolina was assured by the erection of a costly governor's house by Gov. William Tryon in 1767–70. The main building of "Tryon's Palace" burned in 1798, but was restored, along with its two wings, and opened to visitors in 1959. In 1774 the first provincial congress in North Carolina in opposition to the English was convened at New Bern to elect delegates to the first continental congress. After the American Revolution, despite the fact that the assembly met in various other towns, New Bern remained the legal capital of North Carolina until the seat of government was moved to Raleigh in 1794.

As in the Revolution, the city suffered little damage during the American Civil War, having been captured early (March 14, 1862) by Federal troops. A yellow fever epidemic in 1864, however, took 1,300 lives in the area.

Prior to the American Revolution New Bern was one of the leading seaports of North Carolina, trading with New England and the West Indies through Pamlico sound at the mouth of the Neuse, 30 mi. to the east. After the American Revolution, shipbuilding became important and timber and rope were produced. Exports consisted mostly of tobacco, lumber and naval stores.

In the 20th century New Bern, connected by a 12-ft. channel with the Atlantic Intracoastal waterway (*q.v.*) and state-developed deepwater port at Morehead City, became the commercial centre for nearby summer resorts, the large marine corps air station at Cherry Point and farmlands which produce corn, tobacco, soybeans, pulpwood and cotton. Manufactures include lumber products, boats, processed foods, clothing and chemicals.

Noteworthy among the city's older buildings are the Stanly house, now the public library (1780), Attmore house (1790), Presbyterian church (1822) and Christ church, with its communion service presented by George II in 1752.

For comparative population figures *see* table in NORTH CAROLINA: *Population.* (A. T. D.)

NEWBOLT, SIR HENRY JOHN (1862–1938), English author and poet, best known for his patriotic and nautical verse, was born at Bilston, Staffordshire, on June 6, 1862. He was educated at Clifton college and Corpus Christi college, Oxford, was called to the bar at Lincoln's Inn in 1887 and practised law until 1899. His first book was a novel, but it was the appearance of his ballads, *Admirals All* (1897), which included the stirring "Drake's Drum," that created his literary reputation. These were followed by other volumes collected in *Poems New and Old* (1912; rev. edition 1919) in which he extended his range to nostalgic and contemplative poems and affirmed his admiration for traditional English values. He edited the *Monthly Review* from 1900 to 1904 and published several novels including *The Old Country* (1906) and *The New June* (1909). During World War I he was comptroller of wireless and cables, and was later commissioned to complete the official naval history of the war. He also edited various anthologies of verse which reveal his catholic and progressive taste in poetry. He was knighted in 1915, appointed a companion of honour in 1922, and died in London on April 19, 1938.

NEW BRIGHTON, residential community of New York city, U.S., is located on the northeast shore of Staten Island (borough of Richmond) at the junction of Kill Van Kull and upper New York bay, about 6 mi. S.W. of Manhattan. New Brighton had its beginnings in the New Brighton association, founded in 1834 under the leadership of Thomas E. Davis who purchased extensive property in that area.

In 1836 New Brighton was described by the association as a community that "combines advantages, which, it is believed, are unrivalled in this country. Added to its proximity to the great commercial mart of the western hemisphere it possesses a beauty of location, extent of prospect and salubrity of climate that will in vain be sought elsewhere."

In 1866 New Brighton was incorporated as a village enabling the residents to provide themselves with more urban facilities. Horse cars were introduced to connect New Brighton with other villages on the island, the first sewers and street lights appeared, and more and better schools were built. In the latter part of the 19th century New Brighton became one of the most fashionable summer resorts in the east. Only a few of the stately mansions remain as a link with this period when the wealthy patronized the hotels and villas of this area. After 1898 New Brighton was a part of New York city.

Among the points of interest in New Brighton are the Neville house, said to have been built in 1770 and one of the best-preserved colonial houses on Staten Island; the Sailors' Snug Harbor, a home for retired seamen, opened in 1833; and Silver Lake park (207 ac.) which surrounds Silver Lake reservoir. (D. L. D.)

NEW BRITAIN, the largest island of the Bismarck archipelago (*q.v.*), situated to the north of the "tail" of New Guinea. With the adjacent islands, it forms a district of the Trust Territory of New Guinea (*q.v.*), administered by Australia. Pop. (1954) 91,748. Area (including adjacent islands) 14,100 sq.mi.

The island is arc shaped and about 300 mi. long with an average width of 50 mi. It is rugged and mountainous, several peaks exceeding 7,000 ft. and plains are restricted to the coasts. The Whiteman range in the south trends east-west, but farther east the Nakanai mountains extend in a southwest-northeast direction, and in the Gazelle peninsula in the north the Baining mountains have north-south alignment. The mountains are composed of massive limestones, shales and sandstones, with a number of volcanic cones. There are three areas of active volcanism: at the western extremity of the island southeast of Borgen bay; on the Nakanai coast southeast of Open bay where the Father (Mt. Ulawun) and the South Son (Mt. Bamus) both exceed 7,000 ft.; and in the northeast of the Gazelle peninsula near Rabaul, where

the Matupi and Vulcan cones constitute a hazard to the development of the town. An eruption in 1937 killed 263 people. Volcanic activity is, however, responsible for the rich soil in parts of the Gazelle peninsula, the most economically advanced part of New Guinea.

New Britain has an equatorial type of climate, with heavy rainfall owing to the mountains and to a position athwart both prevailing winds, the northwest monsoon (December–March) and the southeast trades (May–October).

The island is divided into four areas: Rabaul and Kokopo, both on the Gazelle peninsula, Talasea on the Willaumez peninsula on the northwest of the island, and Gasmata on the south coast. The most populous area is the Gazelle peninsula where the Tolai people have made greater advances than any other Melanesian peoples. The chief town of the island and administrative centre of the district is Rabaul, an important port of the southwest Pacific, on the northeast shore of Blanche bay. There is a small community of Chinese traders there, and most of the larger settlements have at least one Chinese trader and storekeeper. Rabaul was formerly capital of the Territory of New Guinea, but after the volcanic eruption of 1937 the capital was moved to Lae on the main island.

Only a small proportion of the island is cultivated, but it has the largest area under plantation crops in New Guinea. Most of the plantations are on the Gazelle peninsula coasts. Copra is the principal product and output from native groves has been increasing. The cultivation of other commercial crops, including cacao, has developed further in the Gazelle peninsula than in other parts of the territory. A feature of this development was the success of native co-operative societies with their own driers and fermentaries, a success likely to continue owing to the acute shortage of labour for the plantations, such labour being recruited from the Sepik area of New Guinea 500 mi. away. A variety of crops is grown on village garden land for local consumption but in the more primitive interior a system of shifting cultivation is practised, involving a rotation of plots, only used at long intervals.

New Britain was discovered and named in 1700 by William Dampier, but not explored until late in the 19th century. As Neu Pommern (later New Pomerania) it became part of the German protectorate in 1884, and after World War I was mandated to Australia. It was taken by the Japanese in Jan. 1942 and during 1943–45 Rabaul was severely damaged by U.S. air attacks. The island was re-occupied by Australia in 1945. *See* also Pacific Islands.

NEW BRITAIN, a city in central Connecticut, U.S., conterminous with New Britain town, about 10 mi. S.W. of Hartford, is known as the "hardware city." Pop. (1960) 82,201; standard metropolitan statistical area (New Britain city and Berlin, Plainville and Southington towns in Hartford county), 129,397. (For comparative population figures *see* table in Connecticut: *Population.*) New Britain's predominant nationalities of foreign-born are Polish, Italian, Irish, Swedish, German and English.

Formerly known as the Great Swamp, New Britain came into being in 1754. The township of New Britain was incorporated in 1850 and the city received its first charter in 1870. The township and the city were consolidated by act of the state legislature in 1905.

New Britain and the surrounding area long has been the scene of industrial and manufacturing enterprises. Metalworking began there in the 18th century. Berlin, now a suburb, was the home of the brothers Edward and William Pattison who in 1740 turned out the first tinware made in North America and generally have been credited with inaugurating the tradition of the Yankee pedlar. Berlin also was the home of Simeon North, contemporary of Eli Whitney and a pioneer in the use of interchangeable parts in the manufacture of small arms. Principal modern products include building hardware, household appliances, builders' tools, ball bearings, automatic machines and heating equipment.

An ecclesiastical society, the forerunner of the First Church of Christ Congregational, was organized there in 1760. By 1850, churches for three other Protestant denominations, Baptist, Methodist and Episcopal, had been organized. The first Roman Catholic parish was organized in 1884. A distinguished son, Elihu Burritt (*q.v.*), who was born in New Britain in 1810 and later was known as the "learned blacksmith," gained an international reputation for his efforts in behalf of international peace and brotherhood.

Central Connecticut State college was chartered as New Britain State Normal school, the first in the state, in 1849 and the first instruction was given in 1850, the same year in which a high school was established in the town. The normal school became a four-year college and was renamed Teachers College of Connecticut in 1933; the present name was adopted in 1959. The college offers advanced placement in some subjects and in 1961 inaugurated new programs leading to bachelor's and master's degrees. (A. J. M.)

NEW BRUNSWICK, one of the four original Canadian provinces of the confederation in 1867, lies on the Atlantic coast between 44° 37′ and 48° 3′ N. and 63° 46′ and 69° 3′ W. Roughly square in shape, it measures about 160 mi. in width and 193 mi. from north to south, and has a total area of 28,354 sq.mi. The province has a coast line of approximately 600 mi. along Chaleur bay in the north, the Gulf of St. Lawrence and Northumberland strait in the east and the Bay of Fundy in the south. The province of Quebec forms the northwest boundary, and the state of Maine the international border on the west. In the southeast, New Brunswick adjoins the province of Nova Scotia in the 17-mi.-wide isthmus of Chignecto. The interior is rolling and of moderate altitude, and is well drained by many rivers and streams of great importance to the early settlement and exploitation of the area. Of these, the St. John is the largest, flowing the full length of the province from north to south and navigable for 88 mi. as far as Fredericton (*q.v.*), the capital. The coast line offers a number of harbours, of which Saint John is the most notable. Being ice free throughout the year, it is one of Canada's most important winter ports. Approximately 80% of the province is forested. Cleared agricultural land is largely confined to coastal areas and the major river valleys, particularly the St. John valley; fishing is an active industry around the coasts. The major manufacturing industries are based on these primary resources, with the production of forest products being by far most important to the province's economy.

Physical Geography.—*Geology and Physiography.*—New Brunswick is an extension of the system of uplands and highlands of the Appalachian region which sweeps up the eastern flank of North America. Paralleling the Bay of Fundy in the south are the southern highlands, underlain by the oldest rocks in the province (pre-Cambrian granites). Extending from the southwest to the northeast of the province are the central highlands, a broad band of igneous and metamorphic rocks culminating in Mt. Carleton, elevation 2,690 ft., the highest point in New Brunswick. Associated with the central highlands in the northeast (Bathurst-Newcastle area) are large bodies of valuable base metal ores. To the northwest are the northern uplands, an undulating area underlain by folded Paleozoic sedimentary rocks. To the east is an extensive lowland, developed on flat carboniferous sandstones. Associated with it are the coal seams in the Chipman-Minto area and the natural gas in the vicinity of Moncton.

With the exception of the St. John and St. Croix, nearly all the major river valleys follow the southwest to northeast physiographic trend. Of these the more important are the Restigouche and Nipisiguit flowing into Chaleur bay, the Miramichi flowing into the Gulf of St. Lawrence and the upper section of the Petitcodiac flowing into the head of the Bay of Fundy. Many of the rivers have shallow tidal estuaries. The exceptionally high tides of the Bay of Fundy (over 50 ft.) occasion the peculiar phenomena of the reversing falls at the mouth of the St. John and the tidal bore which rushes up the Petitcodiac river.

Climate.—Like the other Canadian maritime provinces, New Brunswick has a climate characteristic of inland rather than maritime regions. This is especially true in the upper St. John valley and interior areas more directly connected with the continental land mass. The prevailing westerly winds bring with them the weather systems passing from the continent to the North Atlantic. At Saint John, average summer and winter temperatures differ by as much as 42° F. (January 19°, July 61°), while in the interior

variations are even more extreme. Summer highs in excess of 90° F. are occasionally recorded in the interior valleys, while readings of 30° below zero have been observed in the highland areas. Precipitation is normally ample and well distributed throughout the year (the annual average is approximately 40 in. at most stations with 3 to 4 in. monthly). About half falls in the form of snow. The average length of the frost-free season varies from 165 days at Saint John on the coast to 115 days in the upper St. John valley and to fewer than 90 days at higher interior elevations.

Vegetation.—Over four-fifths of New Brunswick was forested in the 1960s (about 14,000,000 ac.). Exploited since the early days of settlement, the forests were largely secondary growth in the second half of the 20th century. About two-thirds were conifers or needle-leaved trees in the following order of importance: spruce (three species), balsam fir, pine (three species), cedar, hemlock and tamarack (larch). The other third comprised hardwood or broadleaved species including birch, maple, beech and poplar, with smaller quantities of elm, ash, oak, basswood and butternut. Typically, the hardwood species grow on the ridge tops while the conifers are found in the valley bottoms and on the lower slopes. There are large areas of peat bog in the poorly drained coastal areas in the northeast of the province, especially in Gloucester county, including Miscou and Shippigan islands, where the extraction of peat moss is an important industry. Along the estuaries of the rivers flowing into the head of the Bay of Fundy are large areas of tidal marshlands developed on the vast accumulation of silts washed in and deposited by the tides. Originally covered with broadleaf and other salt marsh grasses, they have been reclaimed for agricultural use.

Animal Life.—The abundant wildlife of New Brunswick attracts many sportsmen to the province. Deer are especially common, and moose, once almost exterminated, were increased through the enforcement of stringent game laws. In addition there are a large number of fur-bearing animals including the bear, raccoon, marten, otter, lynx, beaver, muskrat, woodchuck, rabbit and red squirrel. The porcupine and skunk are also common. There are over 200 species of birds of which the grouse, duck and Hungarian partridge are the most popular for game. The St. John, Restigouche and Miramichi rivers have a wide reputation as the habitat of the Atlantic salmon, and trout are fished in nearly all the brooks and streams.

History.—Before 1784 New Brunswick formed part, first of the French province of Acadia, second, of the British province of Nova Scotia. The first settlement within its borders was made in 1604 by Pierre de Guast, sieur de Monts, with whom was Samuel de Champlain. Their colony at the mouth of the St. Croix river was soon abandoned, but throughout the French regime the district was frequented by bands of fur traders. In 1762 the first English settlement was made at Maugerville, on the St. John river, and in 1764 a body of Scottish farmers and labourers took up land along the Miramichi.

Scattered French settlers located themselves on the mainland side of the Bay of Fundy. They numbered about 4,500 at the time of the expulsion of their kindred across the bay, and their numbers were increased by about 500 of these as refugees.

After the American Revolution the great influx of loyalists into the valley of the St. John led to the separation of New Brunswick from Nova Scotia in 1784. The close of the Napoleonic Wars in 1815 brought a constant influx of immigration from Great Britain. The province had 74,000 inhabitants by 1824.

New Brunswick shared with Nova Scotia, in the middle period (1815–67), the prosperous development that arose from lumbering, shipbuilding and the fisheries and (until 1849) from the preference of the British market for colonial timber and the effect of the Navigation acts in giving the maritime provinces the West Indian trade denied the United States. This occasioned a relative neglect of agriculture and led many immigrants to prefer settlement in Upper Canada.

The landmarks in the provincial history include the long diplomatic struggle between Britain and the United States over the delimitation of the boundary according to the cryptic terms of the treaty of 1783 which ended in the compromise of the Webster-Ashburton treaty of 1842 (*see* also MAINE: *History*). Provincial history turned also on the question of responsible government, granted after its adoption in Canada (1841–49), and then on reciprocity of trade with the United States (1854). The 1864 plan of confederation for British North America, urged by Canada as a remedy for deadlock and by Great Britain after the warning of the American Civil War, found little favour in the province but in 1866 was voted by the legislature as a reaction from the Fenian raids.

The 1867 union with Canada led to marked improvement in the economic welfare of the province. The Intercolonial railway, promised under the terms of confederation, ran through the east side of New Brunswick and connected Halifax with Montreal in 1867. Other provincial rail lines, including the Saint John to Montreal connection by way of northern Maine, were completed shortly after. However, the introduction of the steamship and the exhaustion of the white pine timber led to the demise of the traditional wood, wind and water economy of the province. Protective tariffs and the concentration of population and industry in central Canada made competition difficult and led to the closing of many local industries. The opening of the Canadian west after 1900 and employment attractions in the rapidly expanding industries of central Canada and the United States started an emigration from New Brunswick which still continues. Various federal government assistance programs—including grants, subsidies and railway freight subventions—proved only moderately successful. In the second half of the 20th century, with the more efficient use of timber resources (chiefly for pulp and paper), the development of local electric-power supplies and the discovery of new mineral deposits, the prospects for economic development seemed more promising.

Incorporated Places of 5,000 or More Population

Place	Population				
	1961	1956	1951	1941	1921

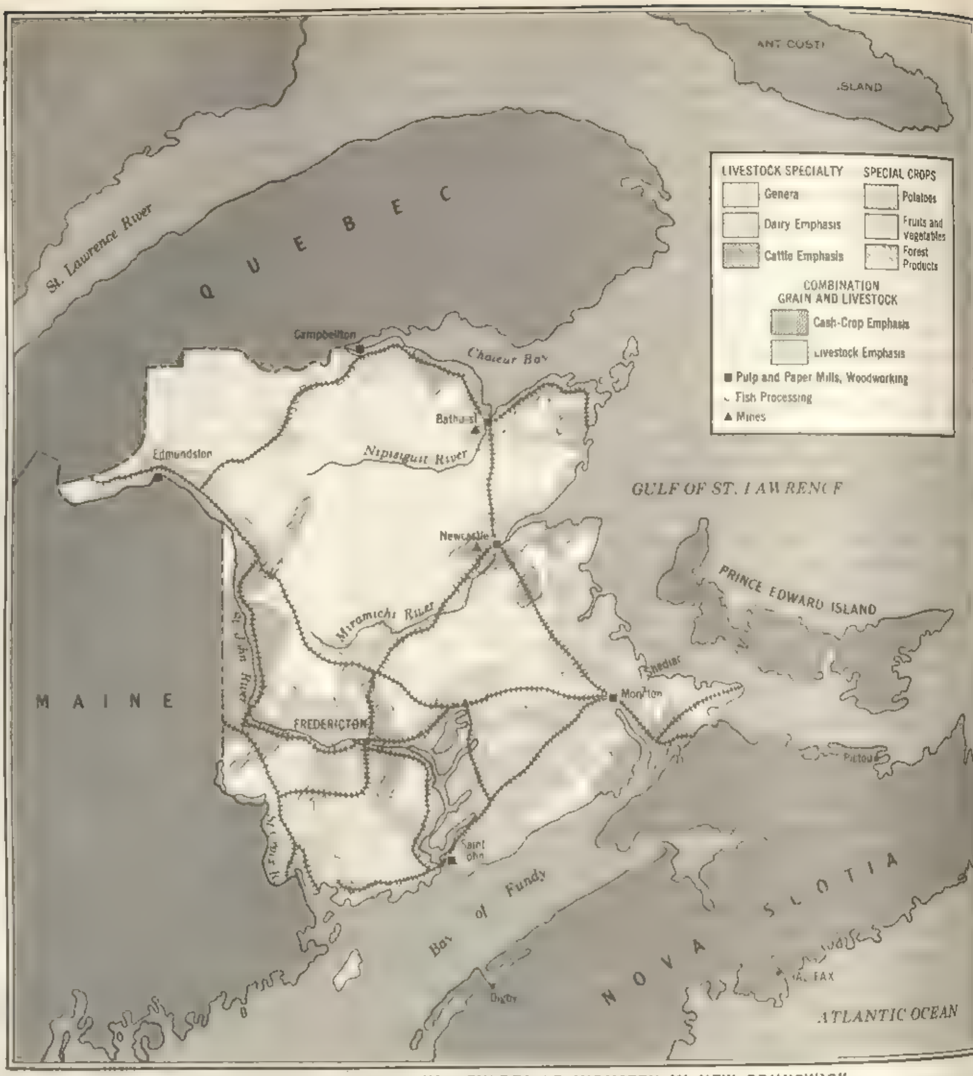
*Previously known as Lancaster Parish.
Note: Populations reflect data as each place was constituted at date of each census. A dash (—) indicates place did not exist during reported census, or data not available.

Population.—The population of New Brunswick grew slowly after 1900 despite the high birth rate; because of heavy emigration, it passed 500,000 only in 1951. In 1961 the population was 597,936, of which the majority were either Anglo-Saxon or French in origin. About 40% of the total were living in the larger cities and towns, of which the cities of Saint John and Lancaster had a combined population of 96,001; Moncton had 43,840; Fredericton, 19,683; and Edmundston 12,791. Other important centres were Campbellton, Dalhousie, Bathurst, Chatham, Newcastle, Woodstock, and St. Stephen. Fredericton replaced Saint John as the provincial capital in 1785 and became a city in 1845 at the command of Queen Victoria. On a broad terrace at the head of tidewater on the St. John river, it has enjoyed a certain importance as a lumber and railroad centre. Persons of French origin made up an increasingly larger proportion of the total population. Descended from the early Acadian settlers and the French Canadians from Quebec who later joined them, they settled chiefly in the upper St. John valley and along the northern and eastern shores. The English-speaking population originates from the Loyalists of 1783 and the large numbers of immigrants who arrived from Britain in the first half of the 19th century. The religious affiliations of the population are, roughly, Roman Catholic, 50%; Baptist, 18%; United Church of Canada, 14%; Anglican, 12%; Presbyterian, 3%; and other, 3%.

Government and Public Finance.—Since 1891 the provin-

cial government has been a one-chamber legislature with 52 elected members representing the province's 15 counties and 2 of its cities. It is headed by the lieutenant governor, who is appointed by the federal government and acts on the advice of the executive council. The executive council is chosen from the legislative assembly and consists of the premier and the heads of departments. In 1960 New Brunswick was represented in the parliament at Ottawa by ten senators appointed for life and by ten members elected to the house of commons for a period not exceeding five years. The counties are organized as municipalities with the parish as the unit of representation in the county councils. In addition there were 6 cities (Saint John, Moncton, Fredericton, Lancaster, Edmundston and Campbellton), 20 incorporated towns and 1 incorporated village in 1960. The sources of revenue collected for provincial purposes embrace various licences, permits, fines, penalties, sales taxes and royalties, augmented by federal government subsidies, health grants, certain equalization and development payments and various tax-sharing agreements.



AGRICULTURAL REGIONS AND CENTRES OF INDUSTRY IN NEW BRUNSWICK

Education.—Public-school education dates from the act of 1871 and is compulsory and free. The system of regional high schools developed after World War II greatly improved the educational facilities, especially in the rural areas. In addition the major centres have institutions which provide vocational training. Degree-granting universities with enrollments over 1,000 after mid-20th century were the University of New Brunswick at Fredericton and Mount Allison university at Sackville; others, with smaller enrollments, were St. Joseph's university, St. Joseph; University St. Louis, Edmundston; Université du Sacre Coeur, Bathurst-Quest; St. Thomas college, Chatham. There is a provincial teacher's college in Fredericton.

Agriculture.—Until about 1900, New Brunswick agriculture was largely a subsistence operation. Mixed farming was carried on with cash income derived from winter lumbering operations or from fishing in the coastal areas. With the opening of the Canadian west in the early 1900s, beef, mutton and grain products could be imported more cheaply than they could be raised locally and maritime agriculture became depressed. Moreover, the enormous expansion of industry in central Canada and the United States provided job opportunities away from home. The result was a large decrease in farm population, in farm production and in improved farm acreage. Agriculture has been increasingly confined to the more favoured areas. About one-third of the farm income is derived from potatoes, a cash crop concentrated in the upper St. John valley. Dairying is important in most areas. More than half of the total cropland (about 600,000 ac.) is normally in hay, with a large additional acreage in pasture. Apples, small fruits and vegetables are grown commercially in the lower St. John valley, and blueberries are a source of income in Charlotte county. Attempts were made after World War II to increase the numbers of sheep and beef cattle in the province and more attention was given to farm wood-lot management.

Forestry.—New Brunswick's forests still provided in the second half of the 20th century the largest source of income in the province (approximately $175,000,000 in the typical year of 1958, for example). Most of this income was produced by pulp and paper mills at Campbellton, Dalhousie, Bathurst, Newcastle, Saint John, St. George and Edmundston; the balance was accounted for in lumber (approximately 200,000,000 bd.ft. annually) and other wood products. New Brunswick had more than 1,000 industrial establishments in the 1960s, of which more than half were based on the use of wood. The province owns nearly half of New Brunswick's forest land and disposes of cutting rights in the form of timber licences and stumpage permits. Over half of the remaining acreage is in farm wood lots and other small holdings from which pulpwood and saw logs are sold to the highest bidder. The balance of the privately owned land is held mainly by operators of forest industries. Growth rates are rapid and compare favourably with other parts of Canada.

Mining.—Large deposits of base metal ores (lead, zinc, copper, silver, pyrite) were discovered in the Bathurst area in the early 1950s and later in the Newcastle area. Construction of Canada's first lead-zinc smelter east of Manitoba began near Bathurst in 1962. A large deposit of manganese ore in the Woodstock area and the oil shales in Albert county also were investigated. Soft bituminous coal, mined for many years in the Chipman-Minto area, was chiefly used in the production of electricity. Gypsum, the second important mineral mined, was used principally for the production of cement at Havelock near Saint John. Small quantities of oil and gas are extracted in the Moncton area, and there is a small tungsten production at Burnt Hill.

Fishing.—Of the more than 30 commercial species of fish

caught in New Brunswick coastal waters, four varieties normally account for over 80% of the total value of the catch (lobsters and sardines are most important, followed by cod and herring). Most of the lobsters were taken from the northern and eastern shores, the sardines from the western Bay of Fundy. With federal government assistance, fishing methods and processing facilities were greatly modernized after World War II, and in the ten years after 1945 the value of the industry almost doubled ($13,000,000, 1945, compared with $23,000,000 in 1956). There were approximately 11,000 fishermen and over 100 fish processing plants by the 1960s.

Power.—The development of New Brunswick's electrical facilities proceeded rapidly after World War II reaching a total installed capacity of more than 300,000 h.p. hydroelectric turbine capacity and 300,000 kw. thermalelectric generating capacity by the early 1960s. The 102,000 kw. Beechwood hydroelectric unit on the upper St. John river was completed in 1958. Steam units were at various points in the province while the hydroelectric installations were on the St. John and its tributaries (Grand Falls, Tinker Falls, Tobique Narrows, Beechwood and Edmundston), the St. Croix, Musquash and Nipisiguit rivers. The possible use of tidal power in Passamaquoddy bay, where a U.S. tidal power project was started in the 1930s (and abandoned in 1937) was again under international investigation in the 1960s (*see* also FUNDY, BAY OF; TIDAL POWER).

Industries.—Although the value of New Brunswick's manufacturing industries increased from $66,000,000 in 1939 to over $300,000,000 by the 1960s, it had consistently declined in relation to the national total (from 7.8% to less than 2%). Manufacturing traditionally has been based on the natural resources of the province, particularly wood. Pulp and paper accounted for about one third the total value in the 1950s and 1960s while other wood products, food, shipbuilding, fish products and textiles followed in that order.

Communications.—New Brunswick is serviced by both the Canadian National and Canadian Pacific railways. The main C.N.R. passenger line from Halifax to Montreal (the old Intercolonial completed in 1876) services communities on the northern and eastern shores, while the main C.N.R. freight lines pass diagonally across the province from Edmundston to Moncton. Other C.N.R. lines connect Saint John and Moncton and serve the lower St. John valley. The main C.P.R. "short line" from Montreal to Saint John via the state of Maine was completed in 1890; branch lines connect with Fredericton, Edmundston and St. Andrews. The C.P.R. operates a ferry service between Saint John and Digby, N.S., as does the C.N.R. between Cape Tormentine and Port Borden, P.E.I. In the 1960s New Brunswick had over 13,000 mi. of roads, of which about 3,000 mi. were improved. Trans-Canada Air Lines service was established on a regular basis from Montreal to Moncton in 1940, and later, direct communications commenced between Halifax and Sydney, N.S., and Moncton, and between Fredericton and Montreal. The Maritime Central Airways began flying in 1941, with flights between Saint John and Charlottetown, P.E.I., via Moncton, and later branched into Nova Scotia and to the Magdalen Islands.

BIBLIOGRAPHY.—James Hannay, *The History of New Brunswick* (1909); D. F. Putnam, *Canadian Regions, A Geography of Canada* (1952); *The New Brunswick Economy*, a brief presented to the Royal Commission on Canada's Economic Prospects (1955). (C. W. RD.)

NEW BRUNSWICK, a city of New Jersey, U.S., is on the Raritan river, 30 mi. S.W. of New York city and 60 mi. N.E. of Philadelphia, Pa.; the seat of Middlesex county. The site was settled in 1681 by a party from Long Island, led by John Inian who established a ferry across the river in 1686. Known originally as Prigmore's swamp, the settlement was called Inian's Ferry in 1713 and finally, about 1724, was named New Brunswick in honour of King George I, who was also the duke of Brunswick. It received a charter from George II in 1730, about the time a number of Dutch settlers from Albany began arriving. Its location at the head of navigation of the Raritan meant that during the colonial period New Brunswick was an important port for the shipment of agricultural products from northwestern New Jersey. During the American Revolution, George Washington and his troops, retreating from New York, occupied the town for about a week in 1776, but had to evacuate at the approach of the British under Sir William Howe who remained there about seven months. Washington again occupied the city after the battle of Monmouth in 1778 and it was there that he issued orders for the march south that culminated in the victory at Yorktown. During this time, small privateers sailed from the city's docks at night to prey upon British ships operating in the waters adjacent to Manhattan. After the war New Brunswick continued to grow and was incorporated as a city in 1784.

In 1834 the city became the eastern terminus of the Delaware and Raritan canal which quickly declined, but continued nominal operations until 1933. The Camden and Amboy (later the Pennsylvania) railroad crossed the Raritan to New Brunswick in 1838 and by mid-century the city was producing wallpaper, rubber products, machinery, shoes and hosiery. In 1896 Robert W. and James W. Johnson established a firm to produce gauze, adhesive tape and surgical dressings. Other manufactures include pharmaceuticals, chemicals, clothing and leather goods.

New Brunswick is the seat of Rutgers—the State university (*see* NEW JERSEY: *Education*), founded as Queen's college in 1766, which became the state university of New Jersey in 1945. New Brunswick Theological seminary, a school of the Reformed Church of America and the oldest theological school in the U.S., founded in 1784, has been in New Brunswick since 1810. Joyce Kilmer, the World War I soldier-poet, was born in New Brunswick. The national headquarters of the Boy Scouts of America is also there.

For comparative population figures for New Brunswick (part of the New York-Northeastern New Jersey standard consolidated area) *see* table in NEW JERSEY: *Population*. (E. R. D.)

NEWBURGH, a royal and small burgh of Fife, Scot., on the Firth of Tay, 11 mi. E.S.E. of Perth by road. Pop. (1961) 2,321. It is the headquarters of the Tay salmon fisheries and other industries are the manufacture of linoleum and of waterproof fabrics. Whinstone (road metal) is exported to England from the harbour. About 1 mi. S.W. of the town stand the remains of a monolith called Macduff's cross where the murderer of Macbeth was reputedly granted rights and sanctuary. A short way east of Newburgh are the ruins of Lindores abbey, a Benedictine establishment founded in the 12th century by David, earl of Huntingdon, brother of William the Lion.

The ruined Denmylne (Denmill) castle, slightly farther east, belonged to the Balfours. At Blackearnside, a forest of alders east of the village, Sir William Wallace defeated Aymer de Valence, earl of Pembroke, in 1298. A Pictish fort with a triple line of earthworks is at Clachard Craig.

NEWBURGH, a city of Orange county in southeastern New York, U.S., lies on the west bank of the Hudson river, opposite Beacon, about 60 mi. N. of New York city and 85 mi. S. of Albany. Temporarily settled in 1709 by German refugees from the Rhenish Palatinate, Newburgh was permanently founded by Scottish and English settlers in 1752 and named after Newburgh, Scot. During the American Revolution, it became prominent as a key command post of the strategic Hudson valley. As Washington's headquarters after 1782, it was there that the general wrote his letter of May 27, 1782, rebuking Col. Lewis Nicola for the suggestion that he assume the title of king; made his reply to the "Newburgh Addresses" calling for action by the army to force congress to redress its grievances; and dissolved his armies in 1783. The headquarters building, a Dutch farmhouse built by Jonathan Hasbrouck in 1750, is now a state museum.

Prospering as a river port and for a while as the terminus of important turnpikes to the west, the city shared in the Hudson river whaling boom and other seafaring activity of the 19th century, but eventually its economy became based on manufacturing and, for a while, the city served as the seat of Orange county. It also became the hub of an agricultural region dominated by dairying and fruit growing.

Newburgh's varied industries include the manufacture of textiles, fabrics and leather goods. Stewart air force base, an installation of the North American air defense command, is located a

few miles to the west. Newburgh was incorporated as a village in 1800 and was chartered as a city in 1865. In 1916 it adopted a manager-council form of government. For comparative population figures *see* table in NEW YORK: *Population.* (D. H. K.)

NEWBURN, an urban district of Northumberland, Eng., forming part of the southern boundary of Northumberland and the western boundary of Newcastle upon Tyne. Pop. (1961) 27,879. In 1204 the name was Niewburg. The Anglo-Scottish battle of Newburn (1640) was fought there and parts of Hadrian's wall are in the district. The church of St. Michael and All Angels dates back to *c.* 1190 with later additions. Newburn is a residential and industrial district and its industries include coal mining, engineering (springs, axles, valves), glass, building materials and cordage. It has a large industrial estate with others projected in the 1960s. Woolsington airport lies 3 mi. N. (C. A. Wo.)

NEWBURY, a market town and municipal borough of Berkshire, Eng., lies 17 mi. W.S.W. of Reading by road on the river Kennet and the Kennet and Avon canal. Pop. (1961) 20,386. Its modernized shops and open-air markets attract an extensive rural shopping population. It is situated at the intersection of the London-Bath and Midlands-south coast trunk roads; an east-west relief road was opened in 1959. The council chamber and magistrates' court and the corn exchange (now used for public entertainment) are in the marketplace.

First inhabited in Mesolithic times, much evidence of Roman occupation has been found. At the time of the Domesday survey there were two mills and the manor was held by Ernulf de Hesding. The manor subsequently passed to the crown and was held by Elizabeth I before her accession. Newbury castle was besieged and captured by Stephen in 1152, and traces of it remained until the 17th century. St. Nicolas parish church is an early 16th-century Perpendicular building on an older site, and was built largely through the munificence of John Winchcombe or Smallwood (Jack of Newbury), an eminent clothier, a part of whose house in Northbrook street still remains. South of the river, in Wharf street, is the Jacobean cloth hall, now the borough museum. Adjoining is an old granary, a long and picturesque two-story galleried building. East of this is the site of the castle.

A charter of incorporation was granted by Elizabeth I in 1596, and revocations and renewals were made by Charles I, Charles II and James II. King John also granted a charter by which the profits of a fair supported almshouses. Borough boundaries were extended in 1878 and 1934. The grammar school was built in 1885, but had its origin in 1466. The town has the right of presentation of boys and girls to the educational foundation of Christ's hospital. Shaw house, a notable Elizabethan mansion associated with the second battle of Newbury and occupied by Oliver Cromwell, is now a secondary school. The suburb of Speenhamland, formerly an important posting station on the Bath road, gave its name to the so-called Speenhamland system of parish relief for unemployment in 1795. Sandleford priory, site of an Augustinian priory (*c.* 1200), is now a school. A racecourse, east of the town, was opened in 1905. The principal industries are marine and light engineering, flour milling, woodworking and the manufacture of light aircraft.

Battles of Newbury (1643 and 1644).—These two important battles occurred during the Civil War. The first took place on Sept. 20, 1643, in the Wash common and Enborne area, when the royalists sought to bar the path of the parliamentary forces under the earl of Essex, returning to their base at Reading after raising the siege of Gloucester. Six thousand men fell in this battle, among them the earls of Carnarvon and Sunderland and Viscount Falkland, a memorial to whom was erected on the site in 1878. In the second battle at Shaw and Donnington, on Oct. 27, 1644, the situation was reversed and a large parliamentary army failed to prevent the royalists from relieving 14th-century Donnington castle, ruins of which remain. *See* CIVIL WAR, ENGLISH. (G. E. Wl.)

NEWBURYPORT, a city of northeastern Massachusetts, U.S., at the mouth of the Merrimack river, 37 mi. N.N.E. of Boston, is one of the seats of Essex county.

Newbury, including the site of Newburyport, was settled in 1635 under the leadership of Rev. Thomas Parker (1595–1677) who had lived in Newbury, Eng. While the western portion of the town was primarily interested in farming, Newburyport's location at the mouth of the river drew merchants, tradesmen and seafarers. This division of interests led to the incorporation of Newburyport as a separate town in 1764. Fishing, whaling, shipbuilding and subsidiary industries brought wealth and fame to the town in the years before the American Revolution. During the war business was virtually destroyed and the shipowners temporarily turned to privateering. By 1790 shipbuilding had recovered and retail trade boomed, but the Jefferson embargo of 1807–08 against all foreign trade, a disastrous fire in 1811 and the War of 1812 brought the end of Newburyport's pre-eminence as a commercial port, although during the clipper ship era of the 1840s Newburyport built a number of those famous ships.

Incorporated as a city in 1851, Newburyport turned to the manufacture of textiles and shoes, along with its traditional products, rum and fine silver. In the second half of the 20th century the electronics and electrical machinery industries were the largest sources of employment. Newburyport contains the birthplace of William Lloyd Garrison (*q.v.*), American antislavery leader, and many of the stately federal-style houses built by early shipowners and their captains.

For comparative population figures *see* table in MASSACHUSETTS: *Population.* (L. G. BA.)

NEW CALEDONIA (NOUVELLE-CALÉDONIE), an island and French overseas territory in the Pacific, lies about 800 mi. E. of Australia. Besides the main island (area, with neighbouring small islands, 8,548 sq.mi.), the territory includes the Loyalty Islands (*q.v.*). Encircled by a great coral reef, New Caledonia is about 250 mi. long and 30 mi. wide. The east coast, which is steep, is composed of ancient Primary (Paleozoic) rocks, and on the west coast, more broken, there are some Secondary (Mesozoic) and Tertiary (Cenozoic) formations. Metamorphic rocks include gneisses, schists and serpentines. All the southeastern area consists of peridotites, which also occur in the north and northeast. The mineral resources include nickel, chrome, cobalt, iron, copper, gold and manganese. A chain of mountains in the interior reaches 5,413 ft. in Mt. Panié and 5,361 ft. in Mt. Humboldt. The climate is subtropical with mean monthly temperatures ranging from about 17° to 32° C. (63° to 90° F.). The rainfall is highest during December–March; on the east coast, which is subject to the trade winds, it is about 80 in. annually and on the west less than 40 in. Four-fifths of the plant species are endemic. There are forests along the east coast and in some valleys, and the west coast has savannas, the *niaouli,* or cajeput tree (*Melaleuca leucadendron*), and Araucaria (*q.v.*) are characteristic. The natural fauna is sparse except for fish.

Capt. James Cook discovered and named the island in 1774, and in 1843 a French Roman Catholic mission was established. New Caledonia was annexed by France in 1853, Nouméa being founded the following year. The island served for a number of years as a penal colony, but free settlers were attracted later. In 1878 abuses of the concessions led to a native revolt. New Caledonia became a French overseas territory in 1946.

The population of the main island in 1963 was estimated at 84,000, of whom 32,000 were Europeans and 42,500 Melanesians. Brought in as a labour force, there are also natives of the Wallis Islands and New Hebrides, Indonesians and Vietnamese. Nouméa, the capital, had 35,300 people. The governor is assisted by a *conseil du gouvernement* elected by the territorial assembly, which is elected by universal suffrage. There are about 50 medical centres, a hospital, two secondary schools and about 250 primary schools. The monetary unit is the franc C.F.P., equivalent to 0.055 fr.

Besides subsistence crops (yams, sweet potatoes, taro, manioc, maize), coconut palms (3,000 tons of copra annually) and coffee (1,800 tons) are cultivated. There is extensive stock breeding with about 100,000 cattle and 20,000 goats. Nickel is mined and accounts for four-fifths of the value of exports, being shipped as ore, smelted metal or castings. Electric power is provided by the Yaté dam and hydroelectric plant, completed in 1959. Nouméa is the port and industrial centre, with blast furnaces for nickel ore, a meat-preserving works and timber mills. The island has

about 1,770 mi. of roads and a weekly air link with France via Australia and another with the United States via Tahiti; ships from France also call occasionally.

See also Pacific Islands.

NEWCASTLE, DUKES OF. Within the space of a century there were four successive creations of dukes of Newcastle in the British peerage. William Cavendish (*see* below), nephew of the 1st earl of Devonshire, was raised to the dignity of duke of Newcastle upon Tyne in 1665. His son and successor, Henry (1630–91), died leaving daughters only; one of these daughters married John Holles (1662–1711), earl of Clare, who was created duke of Newcastle in 1694. This duke died also without male issue, leaving his estates to his sister's son, Thomas Pelham (*see* below), who, with other dignities, had the title of duke of Newcastle upon Tyne conferred on him in 1715, and a second and similar ducal title (that of Newcastle-under-Lyme) in 1756. The first dukedom became extinct at his death, but the second title was granted him with remainder to Henry Fiennes Clinton, earl of Lincoln, at once his nephew and nephew-in-law. From that time the dukedom has remained in the Clinton family.

William Cavendish (*c.* 1593–1676), duke of Newcastle, only surviving son of Sir Charles Cavendish and of Catherine, daughter of Cuthbert, Lord Ogle, was born *c.* 1593 and educated at St. John's college, Cambridge. On the occasion of the creation of Prince Henry as prince of Wales in 1610 he was made a knight of the Bath. He traveled with Sir Henry Wotton, then ambassador to the duke of Savoy, and on his return married his first wife, Elizabeth, daughter of William Basset of Blore, Staffordshire, and widow of Henry Howard, third son of the earl of Suffolk. His fortune was immense, and several times he entertained James I and Charles I with great magnificence at Welbeck abbey and Bolsover castle. In 1620 he was created Viscount Mansfield; in 1628, earl of Newcastle; and in 1629 the barony of Ogle was restored to his mother, this title, together with an estate of £3,000 per annum, descending to him. He was made governor of the prince of Wales in 1638 and in 1639 a privy councilor. When the Bishops' War broke out he assisted the king with a loan of £10,000 and a troop of volunteer horse. He was implicated in the army plot in 1641 and in consequence withdrew for a time from the court. He was sent by Charles on Jan. 11, 1642, to seize Hull, but was refused admittance. When the king declared open war, Newcastle was given the command of the four northern counties; he advanced into Yorkshire in Nov. 1642, raised the siege of York and compelled Lord Fairfax to retire. Subsequently his plans were checked by Sir Thomas Fairfax' recapture of Leeds in Jan. 1643, and he retired to York. He escorted the queen, who returned from abroad in February, to York and thence to Oxford, and subsequently captured Wakefield, Rotherham and Sheffield, but his successes were once more ravished from him by the Fairfaxes, whom he subsequently defeated at Adwalton moor on June 30, obtaining possession of all Yorkshire except Hull and Wressel castle. He might then have joined the king against the earl of Essex, but continued his campaign in the north, advancing into Lincolnshire to attack the eastern association, and taking Gainsborough and Lincoln.

Thence he returned to besiege Hull, and the force which he had left in Lincolnshire was defeated at Winceby by Oliver Cromwell on Oct. 11, 1643, which caused the loss of the whole county. On Oct. 27, 1643, he was created marquess. Next year his position was further threatened by the advance of the Scots. He retreated to York, where the three armies of the Scots, Lord Fairfax and the earl of Manchester surrounded him. Prince Rupert raised the siege on July 1, but the next day threw away his success by engaging the three armies in battle, contrary to Newcastle's desire, at Marston moor. After this disaster Newcastle announced his intention of abandoning the cause and quitting England. He sailed from Scarborough accompanied by a considerable following, including his two sons and his brother, resided at Hamburg from July 1644 to Feb. 1645 and in April moved to Paris. There he married as his second wife Margaret, daughter of Sir Thomas Lucas of St. John's, Colchester. He left in 1648 for Rotterdam to join the prince of Wales in command of the navy, which had revolted, and finally settled at Antwerp. In April 1650 he was appointed a member of Charles II's privy council, and in opposition to Edward Hyde, earl of Clarendon, advocated the agreement with the Scots. In Antwerp he established a famous riding school, exercised "the art of manage" and published his first work on horsemanship, *Méthode et invention nouvelle de dresser les Chevaux* (1658; translated as *A General System of Horsemanship*, 1743).

At the Restoration Newcastle returned to England and regained the greater part of his estates, though burdened with debts, his wife estimating his total losses in the war at £941,303. He was reinstated in the offices he had filled under Charles I; was invested in 1661 with the Garter; and was advanced to a dukedom on March 16, 1665. He retired, however, from public life. Newcastle established a racecourse near Welbeck and published *A New Method and Extraordinary Invention to Dress Horses and Work Them According to Nature . . .* (1667). He also wrote several comedies and with Sir John Dryden's assistance translated Molière's *L'Étourdi* as *Sir Martin Mar-All* (1688). He was the patron of Ben Jonson, James Shirley, Sir William Davenant, John Dryden, Thomas Shadwell and Richard Flecknoe, and of Thomas Hobbes, Pierre Gassendi and René Descartes. Newcastle died at Welbeck on Dec. 25, 1676, and was buried in Westminster abbey. By his first wife he had ten children, of whom one son, Henry, survived him and became 2nd duke of Newcastle. Henry died in 1691 and the title then became extinct.

Margaret (*c.* 1623–73), the 1st duke's second wife, had been maid of honour to Henrietta Maria. The duchess cultivated literary composition with exuberant fervour, and kept a bevy of maids of honour obliged to be ready at all hours "to register her Grace's conceptions." Among many high-flown philosophical works she published two of real merit: her *Nature's Picture Drawn by Fancie's Pencil to the Life*, which includes an autobiography (1656), and *The Life of William Cavendish, Duke of Newcastle*, of which the best edition is that by C. H. Firth (rev. ed., 1906).

Thomas Pelham Holles (1693–1768), duke of Newcastle, was the elder son of Thomas, 1st Lord Pelham, by his second wife, Lady Grace Holles, younger sister of John Holles, duke of Newcastle upon Tyne. Both the families of Pelham and Holles had amassed large fortunes and estates during the 16th and 17th centuries by consistently good marriages and careful attention to their interests. Thomas Pelham Holles inherited the wealth of his mother's family in 1711, and the following year he succeeded his father. When he came of age in 1714 he was, in consequence, one of the greatest landowners in the kingdom. The whole of his influence he threw into securing the succession of George I and the triumph of the Whigs. He was rewarded with the earldom of Clare, and in 1715 he became marquess of Clare and duke of Newcastle upon Tyne. He extended his Whig family connections by marrying Lady Henrietta Godolphin, daughter of Lord Godolphin and granddaughter of the duke of Marlborough. He became lord chamberlain in 1717 and was sworn of the privy council; and the next year, at the age of only 25, he was created a knight of the Garter.

If his inherited possession and wealth gained him early pre-eminence among the Whig families who governed Hanoverian England, it was his long retention of ministerial office which won him most of the personal power and influence which he so much desired. Robert Walpole made him secretary of state in 1724, and he held this important office for 30 years. He survived the fall of Walpole in 1742, gained even greater power when his brother Henry Pelham became prime minister in 1743, and on Henry's death in March 1754 Newcastle became prime minister, serving until Nov. 1756. He was then created duke of Newcastle-under-Lyme. He resumed the premiership in July 1757, and it was in this ministry that William Pitt (afterward earl of Chatham) earned so great a reputation as an efficient, inspiring and brilliant national leader in the Seven Years' War. Newcastle was replaced in May 1762 by Lord Bute, favourite of the young king George III, who

proceeded to make the peace of Paris in 1763. The last five years of Newcastle's life were spent mainly in opposition, though for a few months in 1765 he became lord privy seal. He died in London on Nov. 17, 1768.

The two ruling passions of Newcastle's life were devotion to the Hanoverian succession and the cause of the Whigs, and a love of personal power, influence and the "game of politics" for its own sake. So long as party organization in country or parliament hardly existed, the only means of giving a government cohesion and stability were the systematic management of elections and the distribution of patronage to secure parliamentary support for a ministry. Newcastle won a unique reputation for inexhaustible patience and skill in the arts of managing elections by borough-mongering and influence and of securing a ministerial majority in the commons by distributing posts, sinecures, pensions and all forms of patronage. The extent to which his personal wealth brought him such power has often been greatly exaggerated. What brought him power was his long and unbroken tenure of ministerial office, which put at his disposal the rich resources of the crown. He used these resources not for his own pecuniary profit, for he spent much of his own wealth on similar ends, but for making himself an almost indispensable manager in all the ministries of these years. Jealous of his own dignity and position, and of much abler rivals such as Chatham, fussy and disturbing in his incessant intrigues, he lacked the intellect and the will to shape policy. Although so active in political life for about 50 years, he remained always the political manager rather than the statesman. Ridiculed as "hubble-bubble," distrusted and thought more sinister than he was, this kindly and generous man performed a role in Whig politics which was distasteful to abler men yet was inevitable in the structure of politics of his time.

(D. TN.)

NEWCASTLE, a city and port of New South Wales, Austr., lies on the southern shore of the estuary of the Hunter river, 104 mi. N.N.E. of Sydney by rail. Pop. (1961) 208,630. The town is built at the foot of, and up, a steeply rising hill which backs the harbour, with a well-developed suburban area of more than 80 sq.mi. Its average annual temperature is 22°–12° C. (73°–54° F.) and its average annual rainfall is 45 in. With a large and fertile hinterland (Hunter valley, northern tablelands and Liverpool plains) and abundant coal resources locally, Newcastle was early a notable centre for the export of coal and primary produce. Its possession of fuel, water, food supply, a good commercial position and access to raw materials, has steadily attracted manufacturing industries and it has become one of the leading industrial areas in the southern hemisphere. Its iron and steel industries, established in 1915 by the Broken Hill Proprietary Company Ltd., have expanded to proportions rivalling its coal trade. The coal produced on the Newcastle-Cessnock field (over 10,000,000 tons a year) represents 46% and the iron and steel output (more than 1,600,000 tons) represents 40% of Australia's total annual production. The establishment near Newcastle since 1950 of a large-scale rayon yarn and cord factory and of cotton mills and a wool processing plant were indicative of textile manufacture's becoming its third major industrial development. Newcastle's industries may be generally classified as metallurgical and metalworking; construction engineering and shipbuilding; coke and chemical; textile manufacture; the making of fertilizer, cement, firebrick and pottery; and woodworking. There are also flour and food product industries These are conducted in Newcastle itself or in one of the numerous centres within easy reach of the port.

The harbour (comprising North harbour, the Basin and Port Waratah) has ample accommodation, is well-sheltered and has modern installation for handling cargo and especially for loading coal and bulk wheat. The entrance is by a channel (500–450 yd. wide; average depth 26 ft. to a rock bottom) between breakwaters. Breaking of the rock bar across the entrance was undertaken in 1962 with a view to increasing the depth to 36 ft. Its three miles of wharfage can be extended and it has a floating dock with a lifting capacity of 15,000 tons. Newcastle is the third port of Australia and the second port of New South Wales in respect of trade, with overseas exports amounting to £A40,000,000 and imports to £A10,000,000 a year. Its exports (more than 4,700,000 tons annually) are coal, coke, tar, etc.; frozen meat; butter, eggs; timber; pig iron, steel rails and plates, etc.; and fertilizers. They exceed the imports, which are more than 2,600,000 tons annually About 9,000,000 tons of shipping, of which about half are "overseas" vessels (*i.e.*, other than interstate or coastwise), use the port annually. Newcastle has railway and highway connections to the south with Sydney and to the rich dairy pastures of the north coast, and across the Hunter valley with the wheat, wool and cattle hinterland of the northwest. (W. Bs.)

NEWCASTLE, an urban district and seaside resort of County Down, N.Ire., lies 31 mi. S. of Belfast by road. Pop. (1961) 3,722. Situated on the shore of Dundrum bay at the foot of Slieve Donard (2,796 ft.), the highest Mourne peak, and possessing a famous championship golf course, Newcastle is a popular seaside resort and a centre for exploring the Mourne mountains (*q.v.*). Two miles from Newcastle is Tollymore Forest park, a 1,200-ac. government forestry estate, including 135 species of trees, open to the public as a park and caravan (trailer) site. Light engineering products are made in Newcastle. The "new castle" from which the town takes its name was a Magenis (MacGinnis) stronghold, no longer standing, built in 1588 to replace an older structure. (Hu. S.)

NEW CASTLE, a city of eastern Indiana, U.S., located about 40 mi. N.E. of Indianapolis, is the seat of Henry county. It is the trade centre of an extensive agricultural area which produces livestock, poultry, wheat, corn and tomatoes. Founded in 1819 it was incorporated in 1839.

In 1900 a decade of expansion began when automobile and piano manufacturing, as well as other industries were started there. During this same period the commercial growing of roses gave New Castle the name "rose city." In the second half of the 20th century manufactures included automobile parts, steel products, pianos and children's clothing.

In 1955 New Castle was the scene of a bitter strike at the automobile parts plants. Rioting at the strike-bound plants led to calling out the Indiana national guard and for a short time the city was under martial law.

The historical novel *Raintree County* (1948), by Ross Lockridge, Jr., had New Castle and Henry county for its fictional setting.

For comparative population figures *see* table in INDIANA: *Population*. (H. L. HE.)

NEW CASTLE, a city of western Pennsylvania, U.S., is about 45 mi. N.N.W. of Pittsburgh and 20 mi. S.E. of Youngstown, Ohio, at the point where the Shenango and Mahoning rivers meet to form the Beaver, and is the seat of Lawrence county. Located in the foothills of the Allegheny mountains near the Ohio plain, the city commands a strategic industrial location. Deposits of coal, limestone and fire clay found in the area give it a natural base for manufacturing. Originally a Delaware Indian town and trading centre, it was settled about 1798 by John Stewart who set up a furnace for making pig iron and named the area after Newcastle upon Tyne, the English industrial city. Laid out in 1802, New Castle was incorporated as a borough in 1825 and as a city in 1869. Manufactures include vitrified china, pottery, steel and steel products, brass and bronze castings, cement, firebrick, chemicals and rolling mill machinery. For comparative population figures *see* table in PENNSYLVANIA: *Population*. (C. C. G.)

NEWCASTLE-UNDER-LYME, a market town, municipal and parliamentary borough of Staffordshire, Eng., bounded on three sides by the city of Stoke-on-Trent. Pop. (1961) 75,688. It takes its name from the "new castle" erected *c.* 1144 by the earl of Chester, the feudal overlord in the reign of Stephen, for the greater protection of his fief lying under *i.e.*, near what was the Roman *Limes Britannicus* (Hadrian's wall or the border between the provinces of Flavia Caesariensis, on the east, and Britannia Secunda, on the west). The derivation of the place-name is also attributed to the proximity of the former Lyme forest. The castle served as a bastion during the long war against Wales. The fort

fication, being low-lying, became obsolete in Tudor times, and fell into decay. The town received its first royal charter of incorporation from Henry II in 1173, and the liberties and privileges were confirmed and extended by succeeding monarchs down to James II. In 1267 the borough and manor were granted by Henry III to his youngest son, Edmund Crouchback, and ever since then it has formed part of the duchy of Lancaster. The borough has sent representatives to parliament at least since 1354.

The parish church of St. Giles, the fourth or fifth on the same site, was rebuilt, with the exception of the tower, by Sir Gilbert Scott (1876). The University College of North Staffordshire, founded in 1949, became the University of Keele in 1962. In 1932 the borough was enlarged by the inclusion of Wolstanton (with a fine old church), Clayton and part of Keele. Chesterton (the site of a Roman camp), Knutton and Silverdale also lies within the borough. Industries of Newcastle-under-Lyme include collieries, brick and tile works, a cotton mill, a uniform-clothing factory and light engineering. (H. G. Ss.)

NEWCASTLE UPON TYNE, a city and county, parliamentary borough and port, and the county town of Northumberland, Eng., stands on the river Tyne, 8 mi. from its mouth and 274 mi. N. of London by road. Pop. (1961) 269,389. It is the metropolis of the shipbuilding and industrial area of Tyneside and the principal shopping and marketing centre of the northeast of England.

Five principal bridges over the Tyne link Newcastle and Gateshead: Tyne bridge (1928), taking traffic to the Great North road; the electrically operated Swing bridge (1865–76; one of the greatest engineering achievements of its time) on the site of the Roman and medieval bridges; the High Level bridge (1844–49), over which the railway crosses to Gateshead with road and foot traffic at the lower level, a fine piece of engineering and town planning by Robert Stephenson; and the King Edward VII (1906) and Redheugh (1871) bridges.

Municipal and commercial offices, the main shopping streets and principal places of entertainment in the city are concentrated in the square mile between the Tyne and the Town Moor, and after 1963 a new civic and university centre was constructed for the northern half of this area. The central parts of the city were also refashioned with tall residential blocks, new road systems and shopping and educational precincts. Broad and dignified thoroughfares were laid out by Richard Grainger (1798–1861) and John Dobson (1787–1865) in place of the open ground and unplanned streets which had occupied the space within the city walls. Grey street is perhaps their masterpiece as an example both of dignified urban architecture and bold town planning. Along the river banks to east and west lies the former crowded heart of the city—now largely taken over by business premises—and the remains of the grimly dark and crowded Victorian slums; Scotswood, Elswick and Byker being the most notorious. On the higher ground are pleasanter suburbs, Jesmond, the oldest, and Gosforth to the north, Walker and Heaton to the east, Denton, Fenham and Kenton to west and northwest. There is much new building at Longbenton, Killingworth (a projected New Town), Newburn and Westerhope in Northumberland. Ponteland has developed as a dormitory town. There are 706 ac. of parks as well as the Town Moor (927 ac.).

History.—Newcastle was the site of a Roman station called Pons Aelii. It is possible that a pre-Roman settlement existed there and references to a place called ad Murum ("at the Wall"), and Monkchester (associated with a monastery sacked by the Danes) have been claimed as relating to it. The modern community and its name derive from the Norman castle, built in 1080 by Robert, eldest son of William the Conqueror, and replaced (1172–77) by the impressive stone keep still standing. The keep is a fine example of late Norman architecture and contains a beautiful chapel. The castle dominates the river crossings and the railway and provides a focal point for the old city. The adjoining Black gate was originally the castle gatehouse and contains a small local museum. The best remaining portion of the town walls lies between Westgate road and Gallowgate, near the important remains of the medieval Black Friars' priory. Fragments of Hadrian's wall are visible along the West road and Denton bank. The guildhall, rebuilt 1655–56, stands in the Sandhill, the old city centre.

The diocese of Newcastle, covering Northumberland, Berwick and parts of Cumberland and Durham, was instituted in 1882. The church of St. Nicholas, adopted as the cathedral, is mainly 14th century in date, though there is documentary evidence of a church on that site as early as 1123. The tower and steeple, added in the 15th century, are splendid examples of early Perpendicular. The spire is the finest known work in the style termed "Scottish Crown." St. John's church disputes with St. Andrew's the honour of being the city's oldest church; St. Andrew's was damaged during the Civil War when Newcastle was twice besieged and occupied by the Scots (1644) and Charles I was held prisoner by them in 1646 prior to being handed over to the parliamentary commissioners. St. Mary's, designed by A. W. N. Pugin, completed in 1844, is the cathedral of the Roman Catholic diocese of Hexham and Newcastle.

Administration.—Newcastle upon Tyne is a borough by prescription and had already obtained its own written constitutions before the reign of Henry II. One of its most important charters of incorporation was that of King John, granted in 1216, and the government of the town was thereafter in the hands of local traders and manufacturers, under their elected mayor. Privileges and immunities by royal grant followed rapidly, and in 1400 Henry IV created Newcastle a county separate from Northumberland. Since then it has had its own sheriff and court of quarter sessions, and until 1881 its own assize. Newcastle was represented in parliament by two members from 1283; in 1918 the borough was divided into four single-member constituencies. The ancient constitution of the town, codified by charters of 1600 and 1604, was reformed in 1835, and county borough status was granted in 1888. The town became a city in 1882, and the mayor was given the title of lord mayor in 1906. There have been several extensions of the borough boundaries: notably in 1298 (when the lordship of Pandon was included) and the incorporation in 1835 of Westgate, Elswick, Jesmond, Heaton and Byker. There were further extensions in 1904 and 1935.

Education and Culture.—Of the independent schools in the city, the most famous are the Royal Grammar school, since 1907 occupying premises at Jesmond, which was founded by Thomas Horsley in the time of Henry VIII and incorporated by Queen Elizabeth I in 1600, and Dame Allan's school, since 1935 established at Fenham, which was endowed in 1705. The Municipal College of Commerce and Rutherford College of Technology provide both full and part-time further education. University education is provided by the University of Newcastle (1963), formerly King's college which was founded in 1937 by the merging of Armstrong college and the University of Durham college of medicine. The former was opened in 1871 as a branch of the University of Durham and was the first university college to establish a department of mining. The latter, founded as the Newcastle School of Medicine and Surgery in 1834, was incorporated in Durham university in 1852.

An important collection of Roman inscribed stones and archaeological discoveries is displayed by the Museum of Antiquities of the university and the Society of Antiquaries. The Municipal Museum of Science and Industry is devoted to the development and history of engineering, electrical engineering, mining, shipbuilding, transport and other industries, with special reference to those of Tyneside. The Hancock museum, named after the John Hancock collection of British birds, houses the collections of the Natural History Society of Northumberland, Durham and Newcastle, founded in 1829. Permanent collections of paintings are kept by the Laing municipal art gallery and the Hatton gallery of Newcastle university. The public library has an extensive local history collection which includes local newspapers from the early 18th century, and a fine series of works by Thomas Bewick the wood engraver. Collections of manuscripts and records are maintained by the city archives. The Literary and Philosophical society, founded in 1793, has a library, reading and lecture room. The People's theatre, one of the oldest amateur dramatic societies

(1911) in the country, opened (1962) a new theatre and arts centre. There are also two professional theatres.

Industry and Transport.—Coal is Tyneside's most important natural resource. Mining has continued since the 13th century, though coal exports were less important than wool until the 16th century. London then became dependent on "sea-coal" from Newcastle, and the sarcasm "carrying coals to Newcastle" was coined to convey the essence of an unnecessary journey. Industry and commerce expanded rapidly after the foundation of banking houses from 1755, and the Tyne became a centre for glassmaking, salt and chemical industries, and oil and soap manufacturing. Tyneside's achievements in shipbuilding are famous and its yards contain one of the largest ship repairing centres of the world. The Tyne itself has been navigated since Roman times.

The conservancy of the river was originally vested in Newcastle corporation, but in 1850 control passed to the Tyne Improvement commission. The commissioners accelerated development by dredging above and below the town and improving dock facilities. The corporation quay, almost 1½ mi. long, accommodates even the largest vessels. Exports include iron and steel products, machinery and electrical equipment, coal and coke, and chemicals; imports include wheat and foodstuffs, Scandinavian timber and paper. Much of England's passenger traffic with Scandinavia and the Baltic passes through the ports of Newcastle and North Shields (near the estuary mouth).

Newcastle is an important centre for rail communications with London, northwest England and Scotland. The municipal airport was opened at Woolsington, 6 mi. N.W., in 1935. (Mi. G. C.)

NEW CHURCH (Church of the New Jerusalem, commonly called Swedenborgians) rests unequivocally on the theology of Emanuel Swedenborg (*q.v.*), who himself initiated no organization. His readers in England, however, shortly after his death (1772) felt obliged to do so by their conviction that Jesus Christ in his "Divine Human" (a specifically New Church concept) is the only God in whom is the Trinity, that man's salvation rests less in faith than in his resisting evils as sin against God, and that the second advent was not in person but in the revelation of the spiritual sense of the divine Word. A small group, championed by John Clowes, rector of St. John's, Manchester, advised against the formation of a separate church; but the majority, led by Robert Hindmarsh, prevailed. In 1788 the first building for New Church worship was opened in Great East Cheap, London, rapidly followed by others. In 1789 a conference met in the London church; and, apart from 1794–1806 and 1809–14, the consequent General Conference of the New Church has since met annually. A parallel General Convention of the New Jerusalem in the U.S.A. was founded in the United States in 1817; differences of interpretation within Convention led in 1897 to the formation of the General Church of the New Jerusalem.

Worship, almost invariably liturgical, is addressed directly to Jesus Christ; there is no trace of tri-personalism. Preaching of the Scriptures is usually doctrinal, always practical. Emphasis is on the "inspired" books of the Bible—*i.e.*, 29 books of the Old Testament and 5 of the New, all of which have the "spiritual sense." Baptism and the Lord's Supper are the two sacraments of the church. Marriage is most holy and, when true, continues in heaven. To the established Christian festivals New Church day (June 19) is added.

Candidates for the ministry, apart from those trained in Africa for service there, normally pass through a full-time four-year course in one of the two American colleges (of Convention at Cambridge, Mass., and of the General Church at Bryn Athyn, Pa.) or that in London before being ordained.

The three main organizations all have extensive mission interests; African missions especially are strong. New Church societies, generally allied with one of these three, are small but widespread. Australia has its own conference, closely allied to that in Britain. The New Church groups in continental Europe are nearly all assisted from the U.S. The British Conference and the U.S. Convention annually appoint a general council which, with a ministerial council, is the controlling authority. The General Church is episcopalian. Conference has some 4,500 adherents in 57 societies and several groups in Great Britain; Convention has about 5,000 in the United States, the General Church about 2,000. Membership in the isolated societies and in the various mission fields greatly increases these totals.

NEWCOMB, SIMON (1835–1909), was the greatest American astronomer of the 19th century, although in depth and originality of mathematical invention he was excelled by George W. Hill, his associate for 15 years. Newcomb was born in Wallace, N.S., on March 12, 1835. His father, an itinerant country schoolteacher, records that he taught Simon to count at the age of four, and that before he was five his son was spending several hours a day making calculations in addition and multiplication; before he was seven he had finished the arithmetic book, including the extraction of cube roots.

Newcomb had little or no formal education. At the age of 16 he was apprenticed to a quack herb doctor in Salisbury, N.B. After two or three years he ran away to join his father, widowed in the meantime, in the United States, settling in Maryland as a country schoolteacher. In the libraries at Washington, D.C., he found the first ample opportunity to indulge his intellectual curiosity. After avidly exploring many technical fields he concluded that his principal talent lay in mathematics. He was especially attracted to the *American Ephemeris and Nautical Almanac*, an annual handbook for astronomers, containing predicted positions of the principal celestial objects and other astronomical phenomena. Of this work he says, "Its preparation seemed to me to embody the highest intellectual power to which man had ever attained." He thereupon applied for employment in the American Nautical Almanac office, then at Cambridge, Mass., and became a computer there in 1857. He also enrolled in the Lawrence scientific school of Harvard university, receiving a degree in 1858. In 1861 he applied for and received a commission in the corps of professors of mathematics in the United States navy and was assigned to the United States Naval observatory at Washington, where he worked for more than ten years determining positions of celestial objects with the meridian instruments and for two years with the new 26-in. refractor.

In 1877 Newcomb was put in charge of the American Nautical Almanac office, then in Washington, where almost at once he commenced the great work that he had had in his mind for some years and which was to occupy the greater part of his time for the rest of his life: the calculation of the motions of the bodies in the solar system. Reaching the compulsory retiring age for captains in 1897, he later received the then unusual distinction of retirement with the rank of rear admiral. He died in Washington on July 11, 1909, and was buried in Arlington National cemetery.

In 1884 he had obtained the additional appointment of professor of mathematics and astronomy (which he held until 1893) at the Johns Hopkins university, Baltimore, Md., continuing, however, to live in Washington. For many years he was editor of the *American Journal of Mathematics*. He was one of the founders of the American Astronomical society and its first president (1899–1905). Newcomb received honorary degrees from ten European and seven American universities and was a member of 45 foreign societies. He was awarded the gold medal of the Royal Astronomical society (1874), the Huygens gold medal of the Holland Society of Science (1878), the Copley medal of the Royal society (1890), the Bruce gold medal of the Astronomical Society of the Pacific (1898), the Schubert prize of the Imperial Academy of Sciences, St. Petersburg (1897) and the Sylvester prize of the Johns Hopkins university (1901). He was elected a member of the National Academy of Sciences in 1869, serving as home secretary, 1881–83; vice president 1883–89; and foreign secretary 1903 until his death.

His most important work appeared in the *Astronomical Papers Prepared for the Use of the American Ephemeris and Nautical Almanac*, a series of memoirs that he founded in 1879 with the object of "a systematic determination of the constants of astro-

omy from the best existing data, a reinvestigation of the theories of the celestial motions, and the preparation of tables, formulae, and precepts for the construction of ephemerides, and for other applications of the same results." Of 37 articles filling up approximately 4,500 quarto pages in the first nine volumes, he was sole or principal author of 25. Among them were his tables of the sun, Mercury, Venus, Mars, Uranus and Neptune, and Hill's tables of Jupiter and Saturn, which were in use throughout most of the world for calculating daily positions of the objects from 1901 to 1959, and even afterward for the sun, Mercury, Venus and Mars. This series of *Papers* is remarkable for its sustained high quality. Hardly anything in them has proved to be incorrect, and at mid-20th century they were still worthy of the attention of any student of celestial motions.

Possibly Newcomb's most far-reaching contribution was his inauguration, jointly with A. M. W. Downing, then superintendent of the British Nautical Almanac office, of a world-wide unified system of astronomical constants, which was later to lead to the outstandingly successful scheme of international collaboration among the principal almanac makers of the world that survived two world wars with increasing vigour. Newcomb and Downing were impressed by the "confusion which pervaded the whole system of exact astronomy, arising from the diversity of the fundamental data made use of by the astronomers of foreign countries and various institutions in their work" (Newcomb, *Reminiscences of an Astronomer*). A conference of the directors of the national ephemerides of the United States, Great Britain, France and Germany, was held in Paris in May 1896. It resolved that beginning with 1901 a certain set of constants, substantially Newcomb's, should be used by all the ephemerides. The decision even included some work of Newcomb's that was not to be finished for several years. Although Newcomb was attacked by some astronomers at home for decisions in their opinion premature, time has proved the wisdom of his course. A similar conference, held at Paris in 1950, decided unanimously that the system of constants adopted in 1896 was still preferable to any other for practical use.

Newcomb wrote a number of books, including *Popular Astronomy* (1878), *The Stars* (1901), *Astronomy for Everybody* (1902) and *Compendium of Spherical Astronomy* (1906), some of which have been translated into as many as seven foreign languages. He also wrote on finance and economics and published some fiction. An autobiography, *Reminiscences of an Astronomer*, was published in 1903. A bibliography of his life and works (541 titles) is given by R. C. Archibald, in *Memoirs of the National Academy of Sciences*, xvii, pp. 19–69 (1924). (G. M. Ce.)

NEWCOMEN, THOMAS (1663–1729), English engineer and the inventor of the "atmospheric engine" (the first practical steam engine for pumping water out of mines), was born in Dartmouth, Devon, in 1663. His business as an ironmonger at Dartmouth brought him into contact with the Cornish tin mines, where he became aware of the high cost of using horses to raise water from the mines. With his assistant John Calley (or Cawley), a plumber, he therefore experimented for over ten years with a steam pump. It differed fundamentally from the steam pump of Thomas Savery, who in 1698 had obtained a master patent for raising water by fire. As Newcomen could not patent his engine, he entered into partnership with Savery. The first recorded Newcomen engine was erected near Dudley castle, Staffordshire, in 1712. (For a working description of the device, *see* STEAM.) Newcomen invented the internal condensing jet for obtaining a vacuum in the cylinder and the automatic valve gear; by using steam at atmospheric pressure he kept within the working limits of his materials. Newcomen died in London on Aug. 5, 1729.

See H. W. Dickinson, *A Short History of the Steam Engine*, 2nd ed. (1963). (Ar. S.)

NEW DEAL. The expression "New Deal" came into use to describe the political policies and activities of the administration of Pres. Franklin D. Roosevelt. It was first used by him in his speech accepting the Democratic nomination for president on July 2, 1932. It had been written into the speech by his adviser and collaborator, Raymond Moley, who was the chief of what came to be known as the "brains trust." When it was first used by the candidate it was not intended to describe his philosophy or policies. But the press took it up, just as it had earlier taken up the New Nationalism or the Square Deal of Pres. Theodore Roosevelt and the New Freedom of Pres. Woodrow Wilson.

The term was applied later to a series of proposals, policies and legislation sponsored by President Roosevelt in his first campaign in 1932, in the period between the election in 1932 and his inauguration in 1933, and enacted into law in the Hundred Days' congress of that year. Since the Roosevelt policies shifted abruptly in 1935, it has been said by some historians of the period that there originated in that year a second New Deal.

While the many policies and plans sponsored by President Roosevelt from 1932 to 1935 can hardly be said to belong to any specific political or economic philosophy, most of them tended to emphasize the subordination of private interests to collective interests through the increased power and authority of the federal government. Agricultural subsidies, high taxes and deficit spending brought about a much greater equality in wealth and income than had hitherto existed. In some of the legislation that Roosevelt sponsored there is evidence of economic planning on a national and regional scale through the federal authority.

Since the earlier New Deal was designed primarily for agricultural recovery and for co-operation within industries to promote economic recovery, and since the Roosevelt financial and monetary policies were designed to raise domestic prices, the trend was nationalistic-intranational rather than international. This Roosevelt made clear in his famous "bomb-shell" message, which terminated the World Economic conference in London, July 1933.

Among the major policies enacted into law early in his administration at the instance of President Roosevelt were the Agricultural Adjustment act, the National Industrial Recovery act, the creation of the Tennessee Valley authority, two pieces of legislation regulating the issuance and sale of securities, and a broad reform of the nation's banking structure. The agricultural as well as the industrial planning reforms were later declared invalid by the supreme court. No substitute for the industrial planning reforms was proposed, although a bill greatly increasing the authority of the federal government in industrial relations and strengthening the organizing power of the unions was passed and approved by the president in 1935. This came to be known as the Wagner act, after its sponsor, Sen. Robert F. Wagner of New York. As a substitute for the invalid Agricultural Adjustment act, the president sponsored and congress enacted soil conservation legislation.

With enactment of the Wagner act and the Social Security act in 1935, the emphasis of the Roosevelt policies turned from recovery and agrarian reform to measures designed to favour labour and other urban groups. Thus began the so-called second New Deal, which continued until the crisis in Europe in 1939 brought about the rearming of the U.S. United States entry into World War II in 1941 substantially brought an end to further domestic reform under Roosevelt. He remarked as the U.S. entered the war that "Dr. New Deal" was to be supplanted by "Dr. Win the War."

The lasting effects of the Roosevelt reforms upon the economy and social structure of the United States were the acceptance as national policies of a great increase in the size and authority of the federal government with a consequent diminution of state and local powers; the projection of government authority into private business; large federal subsidies for agriculture, small business, urban housing and shipping; social insurance and old-age and unemployment assistance; high taxes and, with the exception of a few years, deficit financing; great public hydro-power projects; and the government-encouraged progressive growth of unionized labour. Following World War II, the Truman administration largely followed the policies of the prewar Roosevelt administration under the name "Fair Deal." *See* also UNITED STATES (OF AMERICA): *History;* and references under "New Deal" in the Index.

BIBLIOGRAPHY.—Most of the literature bears the influence of the controversies which marked that period, especially the years of the original New Deal 1932–35. Frank B. Freidel, *Franklin D. Roosevelt, the Triumph* (1956), vol. iii is sympathetically objective; Arthur M. Schlesinger, Jr., *The Age of Roosevelt*, vol. ii, *The Coming of the New Deal* (1959) emphasizes with great sympathy the influences of national

planning in the New Deal; E. E. Robinson, *The Roosevelt Leadership, 1933–1945* (1955) is unsympathetic but factual and has the best of all critical bibliographies on the period; Basil Rauch, *The History of the New Deal* (1944) is brief but objective; Ernest K. Lindley, *The Roosevelt Revolution* (1933) and *Half Way With Roosevelt* (1936) are perceptive, sympathetic journalism; Dixon Wechter, *Age of the Great Depression* (1948) is an interesting social history; Broadus Mitchell, *Depression Decade* (1947) is an economic study. Personal accounts by participants are Raymond Moley, *After Seven Years* (1939); J. M. Blum, *From the Morgenthau Diaries* (1939); Frances Perkins, *The Roosevelt I Knew* (1946); Rexford G. Tugwell, *The Democratic Roosevelt* (1957). *Public Papers and Addresses of Franklin D. Roosevelt*, 13 vol. (1938–1950) ed. by Samuel I. Rosenman with comments by Roosevelt. (RD. M.)

NEW DELHI: *see* DELHI.

NEW ENGLAND, the six most northeasterly states of the United States—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut—received its name from Capt. John Smith, who explored its shores in 1614 for some London merchants.

Along its entire length the coastline of New England is indented with harbours, large and small. Of New England seaports Boston early became the most important. Eastward from the coast stretches a broad continental shelf which rises in places near enough to the surface to make grounds favourable for fishing. About 80 species of edible fish live in these waters, made cold by the Labrador current. The most important of these are haddock, redfish, flounder, cod, whiting, pollack and hake. Inland from the coast stretches an uneven hill country that rises into rugged, forest-covered mountains. These, beginning in Maine at the Canadian border, extend into the White mountains of New Hampshire (seen and reported by Smith in 1614) and into the Green mountains, the giant ridge that runs north and south the length of Vermont. The Berkshire hills in western Massachusetts and the Litchfield hills in northwestern Connecticut form the southernmost extension in New England of this geologically ancient system. The last of the ice caps of the Glacial Age covered all of New England save for a very narrow band on Cape Cod. The receding ice left soil filled with stones and dotted in many places by great boulders. Glacial action, in overdeepening old valleys and in depositing moraines or drifts, created over the entire area a profusion of large and small lakes. The largest of these, Lake Champlain, lying in the broad lowland between the Adirondack mountains and the Green mountains, separates the states of Vermont and New York. Of the innumerable streams that flow from the mountains across the rolling lowlands the Connecticut river is the largest and most important. This stream, while navigable in its lower reaches, provides access north of Massachusetts only to a region of little economic importance. In the 17th century the first settlers of New England found iron in bogs, and their successors in the 18th and 19th centuries mined small veins of copper and iron in the ancient rocks of the uplands. But granite, marble and clay comprise the only important mineral resources of the 20th century.

This article deals with the influence of New England, as a section, on U.S. history. Additional historical details and chronology will be found in the separate articles on individual states and in UNITED STATES (OF AMERICA): *History*. *See* also articles on various cities and biographies of persons cited.

Settlement.—The first attempt to settle New England, that of France in 1604 at the mouth of the St. Croix river, the boundary between Maine and New Brunswick, proved abortive. The leaders took the colony to Nova Scotia in the spring of 1605. In 1613 an armed force of Englishmen captured a second French colony at Mt. Desert on the coast of Maine.

In 1620 a company of Separatists, who had found Holland an undesirable refuge from persecution, migrated, with the aid of some London merchants, across the Atlantic to found an English beachhead at Plymouth in New England. Ten years later the Massachusetts Bay company, chartered to trade and to colonize in a designated portion of New England, established what its Puritan sponsors and members looked upon as a new Zion in the American wilderness. Bringing the charter to Massachusetts, John Winthrop turned the management of a trading company into the government of a colony. Persecution by the English government of the growing Puritan party caused some 20,000 persons to cross to Massachusetts between 1630 and 1640. In the new world the Puritans laid out villages whose centre of life was the parish church. Following the precedent set by the Pilgrims the government of the church became congregational. A systematic allotment of land reinforced the close social structure of the Puritan villages (*see* LAND SYSTEM [U.S.]).

Other Puritans from England founded New Haven colony in 1638. Some of the Massachusetts Puritans, dissatisfied with the government of that colony, moved westward to found three towns on the Connecticut river—Hartford, Wethersfield and Windsor. In 1662 New Haven, the Connecticut river towns and another settlement at Saybrook united to make the colony of Connecticut. Roger Williams, pastor of the church at Salem, opposed the religious intolerance of the Massachusetts magistrates and even questioned the right of the English crown to grant territory in America that had not first been purchased from its Indian owners. Williams, circumventing a decree of banishment, led followers in the spring of 1636 to Narragansett bay, where he founded Providence.

North of the Merrimack river Capt. John Mason received a grant from the crown and sent settlers to the mouth of the Piscataqua (Portsmouth). His plans for an aristocratic domain modeled on the medieval county palatine (*q.v.*) as well as his appointment as governor general of all New England came to naught with his death in 1635. His settlers came under the rule of the Massachusetts Bay company until organized as a royal province (New Hampshire) in 1679. Farther northeast another royal proprietor, Sir Ferdinando Gorges, planned to colonize. Ultimately his enterprise failed in competition with Massachusetts settlers. His heirs sold their claims to Massachusetts in 1677 and the region, under the name of the district of Maine, remained a part of Massachusetts until erected into an independent state in 1820. In the latter half of the 18th century settlers moved into the region north of Massachusetts and west of the Connecticut river and occupied land under grants from New Hampshire. But the province of New York claimed the region. In 1764 an Order in Council adjudged the country between Lake Champlain and the Connecticut river to be part of New York but without prejudice to the grants from New Hampshire. The status of the region remained in dispute and unsettled until 1790 when New York state relinquished its claim. Congress admitted Vermont to the union in 1791.

Colonial New England.—New England was founded by religious refugees who were strongly influenced by the teachings of John Calvin. In America circumstances compelled them to set up a separate (Congregational) church. They were uncompromising Sabbatarians. They opposed the theatre as immoral. They replaced the ritual of the Church of England with a plain service in a plain meetinghouse. The centre of the service was the sermon and extemporaneous prayer. Puritan prudential ethics sanctified work, insisting that faithful attention to the secular calling was, in itself, worship of God. Discouraging idleness and luxury, and glorifying saving, Puritan ethics served admirably the needs of frontier communities where the work to be done was prodigious and the hands to perform it few.

Many of the leaders of the Puritans were university men, particularly from Cambridge. As a consequence New England Puritans held learning in high esteem and insisted on an educated clergy. Massachusetts required each town to provide education for its children. To train men for service in church and state Harvard college was founded in 1636 and Yale college in 1701. Sometimes local pastors prepared boys for admission to these institutions by teaching them Latin and Greek. Grammar schools (Boston Public Latin school and Hopkins Grammar schools in New Haven and Hartford) arose to perform more effectively the same function.

From their beginnings the New England colonies (like the other mainland colonies) enjoyed representative government. The towns managed their affairs through the direct democracy of the town meeting. The Fundamental Orders of Connecticut, a kind of 17th century constitution of the three river towns—Hartford, Windsor and Wethersfield—proclaimed the principle that government must rest on the consent of the governed and that liberty im-

plied liberty under law. Roger Williams' Rhode Island from its beginning in 1636 guaranteed religious freedom. The charters granted to Connecticut and Rhode Island by Charles II after the Restoration were surprising documents for the 17th century in that they provided not only for representative government but for the election of the provincial governor within the colony. Save for the reserved power of the crown to disallow acts passed by their assemblies these corporate colonies were virtually tiny independent republics. In this characteristic they differed in the 18th century from Massachusetts, which had lost its charter in 1684 and had become a royal colony.

The End of Colonial Status.—In the 18th century as the frontiers of New England pushed westward and northward the greater part of the population lived by agriculture. Husbandmen cleared fields high on the slopes of hills and mountains to take advantage of the fertility of the rich mold under the primeval forest. It was the day of the self-sufficient farm. The land on which the family lived provided materials for practically all its needs—timber for house and barn (often one continuous building in northern New England), fuel, food, wool and flax for cloth, leather for harness and shoes. Primitive roads and the almost complete absence of bridges made transportation and communication difficult. Self-sufficiency was an adjustment to isolation. But colonial New England enjoyed three advantages that led to special economic developments. Shipbuilding flourished in many harbours at the mouths of rivers. On these streams logs from the forest in the interior could be floated to the yards. The making of ships began with the founding of the Massachusetts Bay colony when Winthrop's "Blessing of the Bay" was launched in 1631. New England ships found a ready sale because the English Navigation acts admitted colonial-built vessels to the status of English ships in the monopoly of the carrying trade of the expanding empire. Many boats were constructed for the fisheries, which from the beginning of settlement remained an important part of New England's economy, providing food for the colonials and an important item of external trade. Good harbours and available ships stimulated the growth of the sea trade. Merchants in Boston and other coast towns ventured in commerce with England and with the British and French colonies in the West Indies.

New Englanders, like other colonials, resented the increasing enforcement after 1763, when New France fell, of the principles of mercantilism on which British imperial policy was based. They looked upon a succession of parliamentary acts as denials of their traditional rights as Englishmen.

The American Revolution broke out in 1775 when New England minutemen engaged, at Lexington and Concord, in armed conflict with a detachment of British regulars sent from Boston to destroy military stores being gathered by the colonial militia.

New England played its chief part in the American Revolution during the years 1765–1775 in defining issues and precipitating hostilities. In the continental congress the New England colonies early supported the independence movement in 1776. After the evacuation of Boston by the British army on March 17, 1776, New England saw only minor military actions, but Connecticut became a major source of supply for Washington's army. After 1775 the irreconcilable temper of New England people convinced the British military leaders in America that attempts at conciliation or subjugation had a better chance of success elsewhere. Tories, while important as economic and social leaders, did not constitute a large percentage of the New England population. Many of them fled to Nova Scotia, New Brunswick and England when the British army left Boston. The revolt against the mother country brought less civil war between rebels and Tories in New England than occurred farther south. Control of the governments of the newly independent states fell into the hands of conservatives who assumed the political offices and the economic and social leadership vacated by the fugitive loyalists.

New England in the New Nation.—The period of disorganization which followed the cessation of hostilities brought suffering to many communities. The disruption of the old courses of commerce within the British empire, no longer supplemented by privateering and wartime trade with other countries, caused a lack of specie. The departure of British armies, which had purchased supplies in the colonies, contributed to the same deficiency. Farmers who had gone into debt in the development of their holdings found themselves facing difficulties when interest payments and taxes were due. Distress led to a demand, most successful in Rhode Island, to print paper money whose depreciation would assist the debtor and work to the disadvantage of the creditor. In the western counties of Massachusetts and New Hampshire opposition to the tax collector and to court action against debtors was terminated by a show of force and belated remedial measures.

Although New England leaders played prominent parts in the Constitutional Convention, actual ratification proved a difficult matter in Massachusetts and New Hampshire. Rhode Island rejected the instrument until after the new federal government was organized. The creditor and mercantile sections of the population supported the stronger national government provided in the constitution in the hope that the national credit would be established and a national currency created that would have stability. Supporters of the constitution hoped that a national tariff might be used to persuade reluctant European governments to open their home and colonial ports to American trade. For nearly a decade after the inauguration of the new government under Washington the superior organization of the dominant commercial interests committed New England as a whole to the Federalist party. But Jefferson, representing the common man and the agrarian interests, had sufficient success in organizing anti-Federalist elements to carry several representative districts in the election of 1800.

The basis of New England's prosperity in the Federalist period seems to have lain in the application of Yankee energy and resourcefulness to the exploitation of the peculiar advantages of New England in foreign trade. Its ships, restricted in their enterprises in the older fields under the control of the British crown, turned to the Mediterranean and to the Pacific and Indian oceans. In 1786 Samuel Shaw established in Canton the first American mercantile house in China. In 1787 the "Grand Turk" brought to Salem the first of the many oriental cargoes which made that port famous. In 1787–90 Capt. Robert Gray's "Columbia" carried the flag of the new republic around the world for the first time and laid the foundations not only for the U.S. claim to Oregon but also to the very profitable trade with the northwest coast. There, furs were obtained which could be exchanged in China for silks and tea. Salem became for a time the tea market of North America and Europe and the third city in the union.

The Napoleonic Wars shattered this prosperity. Jefferson's embargo, continued in milder form under Madison, struck a heavy blow at New England commercial interests. The War of 1812, strongly opposed in New England, brought opportunities for privateering and the profits of blockade-running. But commercial interests suffered. The disaster of the war plus concern that westward expansion of the nation, made possible by the purchase of Louisiana, would seriously reduce the relative political power of New England led to a secession movement. This came to climax in the Hartford convention which formulated demands for drastic changes in the constitution. News of the signing of a peace treaty coming immediately after the convention adjourned made the New England effort abortive.

The sea trade revived after the war. In the 1840s New England shipyards created the clipper ships, in their day the fastest sailing vessels afloat. By reducing materially the sailing time to the orient, they brought large profits to their owners. In the 1830s and 1840s a large New England whaling fleet, mostly out of New Bedford and Nantucket, pursued their profitable prey in all the oceans.

Manufacturing using the machines of the Industrial Revolution began in New England near the end of the 18th century. The disaster of the embargo and the interruption of trade caused by the War of 1812 caused a shift of New England capital from commerce to manufacturing. Dams across the numerous rivers provided power. Textiles, shoes, clocks, hardware and articles of wood entered the market in increasing amounts. Itinerant Yankee pedlars distributed "Yankee notions" in the middle states and the south and as far west as the Mississippi. The rapid expansion of

the agricultural regions of the south and west from 1815 to 1850 brought into the eastern market cheaper cotton as well as cheaper foodstuffs. The former stimulated more textile activity; the latter drove the less well-situated farmers to abandon their farms and migrate to the west. In fact New England contributed greatly to westward expansion as migrants from New England moved early to the old northwest and later to Iowa, Kansas and Oregon. Through these pioneers on new frontiers New England continued to exert the peculiar influence of its Puritan traditions.

The growth of manufacturing bound New England to the nation because of the need for cotton and for an expanding market. Sectionalism gave way to a strong nationalism. Beginning with the tariff of 1816 New England supported protection but after 1833 the strong opposition of the agrarian south prevented the maintenance of a strong protective policy. New England was a pioneer in railroad experimentation. One of the first railroads in the U.S. was built in 1826 to carry granite blocks from the Quincy quarries to tidewater. In the 1840s short lines were built connecting Boston with Providence, Lowell, Portsmouth, Springfield, New Haven and New York. The railroad brought to an end the period of self-sufficiency in New England farming. Husbandmen raised crops to sell in the growing industrial towns. But location excluded New England from the competition in canal, highway and railroad building for access to the west which engrossed the attention of the states to the south. Although in 1850 Massachusetts ranked third to New York and Pennsylvania in railroad mileage these railroads failed to secure connections with the great productive areas of the Mississippi valley, so that Boston, as a port of export, fell behind its rivals. Yet New England had its own expansion. Its northern and eastern regions—Vermont, New Hampshire and Maine—were losing their frontier character. The northern boundary, long subject to dispute even to the extent of an armed clash in 1839 known as the Aroostook War, was finally determined by the Webster-Ashburton treaty in 1842. By that arrangement a large area in northern Maine came under the permanent jurisdiction of that state. The victory for New England claims stimulated the sentiment of nationalism. During the Civil War, New England, where antislavery sentiment was very strong, stoutly supported the cause of the Union.

The war brought to an end a phase of New England life. New England commerce had suffered severely. The whaling fleet was broken up by Confederate raiders, and its monopoly of the illuminating-oil market was destroyed by the introduction of kerosene and gas. By the change from wooden to iron and then steel ships and by the rising costs of operation under the U.S. flag, all the natural advantages in construction and operation of ships which New England formerly possessed were lost.

New England in a Changing America.—Between 1855, and the subsequent development of the Bessemer process for making cheap steel, and U.S. entry into World War I the country underwent its Industrial Revolution. By the end of that period the region east of the Mississippi and north of the Ohio and Potomac rivers had become thoroughly industrialized. New England, where industrialization had gotten under way early in the 19th century, kept its place in the forefront of the economic advance. Throughout the period it was a high income area. New England cities burgeoned as did those throughout the entire industrialized area. The need for labour brought a social change that has been called the "conquest of New England by the immigrant." The Irish came first to help build the railroads, to work in the mills and to transform Yankee Boston into something approaching an Irish city. Italians, Poles, Swedes, Czechs, Slovaks, Ukrainians, Lithuanians, Magyars and French Canadians combined to bring about in New England a veritable ethnic revolution. The newcomers added colour, character and a cosmopolitanism to the communities of the region. In the great variety of manufacturing enterprises they acquired the skills that enabled New England to hold fast to an old tradition. One of the most important assets of the region in the 19th century (and continuing into the second half of the 20th) was the existence of a numerous and highly skilled labour force.

In the 20th century, and particularly after World War I, New England's economic position was seriously disturbed by the impact of new trends in several fields. The demand for both granite and marble from the Maine coast and the Green mountains of Vermont declined with the extensive use of cement and steel in construction. Lumber for the building trade, which reached its peak in the 1860s, when 60 schooners came down the Penobscot river from Bangor, was displaced by lumber from Oregon and Washington or by other materials. Most timber by mid-20th century fell into the class of pulp for paper mills and had to compete with Canadian and southern products. In the second half of the 20th century Aroostook county, Me., the Connecticut valley and the area adjacent to Plymouth and Cape Cod remained the only sections where extensive agricultural operations were still profitable. There, potatoes, tobacco, onions and cranberries are raised for export. Forests moved in to take over land no longer profitable for crops. The result was the paradox that in one of the most highly industrialized regions in the world 77% of the land area is occupied by forests. Though important national and state forests exist, most of the wooded country is privately owned.

After World War I some New England textile industries moved to the south where they would be nearer to raw materials and also in a lower wage area. The danger that communities, such as Manchester, N.H., which had primarily depended upon textiles would become ghost towns was averted by the development of new and diversified industries. The existence in and near New England of important markets was a prime factor in attracting industry. The council of economic advisers reporting to the president in 1951 described that market in *The New England Economy:* "The northeastern part of the country is the most densely populated. Its inhabitants have higher than average personal incomes and conduct more than their proportionate share of manufacturing and much other business activity. The New England and Middle states alone contain 26.4 percent of the nation's population and receive almost one-third of the nation's income." The characteristics of New England industry and its relative position in the national economy are suggested by W. Storrs Lee's summary of Connecticut enterprises. "The state still produces more than half the nation's hats, firearms, fabricated brass products, ball bearings, typewriters, springs and counting devices; only one other state exceeds her productivity in machine tools, cutlery, needles, pins, hooks and eyes, snaps and zippers; it ranks first in the production of aircraft engines, firearms, felt hats, non-ferrous metal products, silverware, clocks, hardware, insulated wire and cable, office and store machines, and mechanical transmission." (*Yankees of Connecticut*, p. 230, Henry Holt & Co., Inc., New York, 1957.) As industrialization spread over much of the United States, New England lost its former pre-eminence. Its rate of growth became slower than that of newer industrial areas. But in an absolute sense progress continues. Diversification has gone beyond manufacturing. If the pre-Civil War merchant marine that sailed from New England's ports has disappeared, the region contains in Hartford, Conn., the "insurance capital" of the nation. New England's mountains, lakes, rivers and seashore are not only available for the enjoyment of the people of the region but attract a sufficient number from beyond its borders to make the tourist business a major industry.

Cultural Influences.—The first settlers of New England had a deep interest in religion and in education. In Jonathan Edwards New England produced one of the chief theologians and philosophers of the English-speaking world in the 18th century. From Edwards, among other origins, stemmed the evangelical impetus that gave power not only to early 19th-century Congregationalism but to the other Protestant denominations that had become important in New England. At the same time Unitarianism under the leadership of William Ellery Channing softened the harsh rigidities of the old Calvinism by stressing the humanism and the emphasis on reason of the Enlightenment. Transcendentalism as expressed by Emerson, Phillips Brooks and Horace Bushnell replaced the distant God of Calvin with an immanent deity abiding in the hearts of men. The concept of an immanent deity became central to the theology of the social gospel, important in New England churches at the turn of the 20th century. After the middle

of the 19th century, however, the Protestant monopoly of New England religion rapidly disappeared. Beginning with the Irish, the immigrants brought Catholicism to the region and to the nation. By the middle of the 20th century Catholics made up a large percentage of the population of the three southern states of New England.

After the founding of Harvard and Yale the interest of New Englanders in higher education expressed itself in the establishment of Brown (1764), Dartmouth (1770), Williams (1791), Amherst (1825), Massachusetts Institute of Technology (1861), Bowdoin (1794) and Smith (1871), to mention only the more famous of the institutions which appeared. In the 20th century all were independent institutions. Only in the middle years of that century did the state universities begin to reach a stature that could be said even to approach that of many of such institutions west of the Appalachians. In the 19th and 20th centuries New England became a centre for privately endowed preparatory schools. But Horace Mann of Massachusetts and Henry Barnard of Connecticut were the two most important pioneers in bringing about the American public school system supported by taxation and with trained teachers in the classrooms. In New England the Catholics created and supported their own school system from kindergarten through college.

In the first half of the 19th century evangelical Protestantism stimulated the development of many humanitarian and reform movements in the nation and particularly in New England. Dorothea Dix of Massachusetts pioneered in the reform of the treatment of the mentally ill. Lyman Beecher of Connecticut was an initiator of the temperance movement. William Lloyd Garrison of Massachusetts led a militant abolitionism. Elihu Burritt of Connecticut founded an international peace society. Beginning at Williams college early in the 19th century a missionary movement to foreign lands and to the American frontier carried outward from New England not only religion but education and medicine.

In two villages, Concord and Cambridge in Massachusetts, appeared the most important groups in the first flowering of American letters. Emerson, Thoreau, Hawthorne, Longfellow, Holmes and Lowell created an enduring literature. Outside the region Irving and Cooper preceded them and Whitman followed. Only Poe and Melville among the major figures were their contemporaries. After the Civil War the solitary Emily Dickinson of Amherst wrote the poetry that gave her rank among the best. Henry James fled New England at the height of the Industrial Revolution to become an expatriate in England but one who in his writings could not escape the fascination of the American theme. Meanwhile his brother William, borrowing an idea from the logician Charles Peirce, formulated at Cambridge the American philosophy of pragmatism. In the 20th century Eugene O'Neill of Provincetown and New London brought American drama to eminence.

New England in the 20th Century.—For roughly two centuries—from the landing of the Pilgrims in 1620 to the Hartford convention in 1814—New England was a peculiar and self-conscious region whose leaders in the latter year gave serious thought to the possibility of setting up their own independent nation. In the century from the War of 1812 to World War I, New England, accepting the role of a small region in a nation of continental size, led the way in the creation of industrial America, produced a literature that ranked with that of contemporary England and exported thousands of its people to the territories and the states beyond the Appalachian mountains. These migrants carried with them from their rocky eastern hills the New England ethics and regard for things of the mind. After World War I the forces making for standardization in a dynamic civilization rubbed away, for the most part, the angularities that had so long given New England its distinctive character. But uniformity did not triumph completely. The New England past was prologue in the mid-20th century to a present in which, in a new age, a traditional spirit of enterprise carried on in the face of continuing disadvantages.

In manufacturing, no giant mass-production industries took form. Limited supplies of power and lack of local raw materials suggested to New England enterprisers that they concentrate, like their counterparts in Switzerland, on products of small bulk and of high quality and value. In an age of relative decline on the part of railroads New England built arterial highways east and west across Connecticut and Massachusetts that connected with others running north and northeast in New Hampshire and Maine. The new highway network increased the mobility of goods and persons within the area and, by being joined with the highway system of New York state, maintained for New England effective contact with the rest of the nation. If transoceanic airways and seaways bypassed New England, the busy life of the region brought about a considerable airborne and seaborne commerce. Suburbs pushed out from the major coastal cities until the "long street" from Boston to New York and beyond became almost a literal reality. If the growth of suburbia threatened parent cities with decay at the centre, New Haven's thoroughgoing destruction of obsolete downtown commercial structures and its creation of a modern city centre demonstrated community readiness to face realities and determination to keep in the van of 20th-century progress. The fact that the many-times-elected mayor who led the community effort was of Irish extraction suggests that the new Yankee who appeared after the conquest of New England by the immigrant possessed an enterprise and vision equaling that of the early 19th-century Yankees who built Lowell, Mass., and Manchester, N.H.

In the arts the Boston symphony orchestra achieved a position second to none. Its Berkshire Summer festival became a national cultural event. In the same period Yale established the first school of music of graduate level in the United States. In architecture New England, while cherishing the tradition of 18th century Georgian expressed in carefully guarded old houses and churches, welcomed the new philosophies and new forms of modern architecture. The theatre and chapel at the Massachusetts Institute of Technology and the hockey rink at Yale expressed freedom and creativity. A concentration of institutions of higher learning within its small area made New England in the 20th century an intellectual centre unequaled in the nation. Thornton Wilder's *Our Town* summed up the region: the play's theme is universal, but "Our Town" remains a New England village.

NEW ENGLAND PRIMER, the "Little Bible of New England," was a famous children's schoolbook published sometime before 1690 by Benjamin Harris (fl. 1673–1716), who, in Sept. 1690, published the quickly suppressed first issue of the first newspaper printed in the colonies, *Publick Occurrences Both Forreign and Domestick*. The catechism contained woodcuts illustrating the alphabet, crude couplets and moral texts, including the child's prayer "Now I Lay Me Down to Sleep." Frequently revised, it was an important children's textbook for more than a century.

NEW FOREST, one of the most densely wooded regions of England, lies in southwest Hampshire between Southampton water, the Solent and the Avon river. Agriculture is important on the coastal fringes. Inland the infertile, sandy or gravelly soil supports only woodlands or broad heaths grazed by the ponies and cattle of the "commoners," small farmers holding ancient grazing rights. This region of unique scenic beauty, administered under special acts of parliament, serves many of the recreational purposes of a national park.

The New forest, mentioned in Domesday Book, was a hunting ground of the West Saxon kings, but derives its name from being placed under forest laws by William the Conqueror in 1079. It has been reduced since Norman times, but its legal "perambulation" is still 130 sq.mi. Of this, 30 sq.mi. are privately owned, while 100 sq.mi. are controlled by the Forestry commission. The

45 sq.mi. of crown woodlands form a valued reserve of timber. The main centres are Lyndhurst; Fawley; Lymington (*q.v.*), a yachting port and Georgian town beside the Solent; New Milton; and Ringwood, a market town in the Avon valley. Beaulieu village on the estuary of the Beaulieu river has ruins of Beaulieu abbey, founded by King John for Cistercians. Many of Lord Nelson's wooden battleships, built of New Forest oak, were launched from the slipway that may still be seen at Buckler's Hard. (H. L. En.)

NEWFOUNDLAND is the tenth province of Canada, having entered the confederation on April 1, 1949. It comprises two main areas, the Island of Newfoundland and the Coast of Labrador, a total area of 156,185 sq.mi. The Island of Newfoundland, roughly triangular in shape, is separated from the Canadian mainland by the narrow Strait of Belle Isle on the northwest, the broad Gulf of St. Lawrence on the west and the 68-mi.-wide Cabot strait on the southwest. The island has an area of 42,734 sq.mi., of which 625 sq.mi. is fresh water. The Coast of Labrador extends northward from the Strait of Belle Isle to Hudson strait and inland to include the area draining eastward. Consequently, the Labrador-Quebec boundary follows the irregular and twisting drainage divide. The Coast of Labrador has an area of 112,826 sq.mi. (of which 10,195 sq.mi. is fresh water), considerably larger than that of the island.

The population of Newfoundland in 1961 was 457,853, of which only 13,534 lived in Labrador. St. John's, on the island, is the largest city and the capital of the province. Historically, the Newfoundland economy has been based essentially on the codfishery, but in the 20th century forest and mineral industries have become increasingly important. The fishing industry itself has changed in character, with greater mechanization and new methods.

This article deals with various aspects of the Island of Newfoundland and with the political history of the province, including the Coast of Labrador.

For the physical geography, natural resources, etc., of the Coast of Labrador *see* Labrador-Ungava.

PHYSICAL GEOGRAPHY

The Island of Newfoundland is considered to lie within the Appalachian physiographic province, related in structure to the whole eastern seaboard of North America (*q.v.*). The great diversity of rock types which have undergone metamorphism and faulting are complex in structure. Nevertheless, there is a marked northeast-southwest alignment of the rock formations which conforms with the trend throughout the Appalachian system. Rocks of Pre-Cambrian Age constitute the Long Range mountains which parallel the west coast, parts of the interior and the southern part of the island, including the Avalon peninsula, joined to the island by a narrow isthmus, at the extreme east. Much of the central portion of Newfoundland is made up of Paleozoic sediments, chiefly Ordovician in age, and intrusives of Acadian (Middle Cambrian) Age.

The island may be regarded as a rugged plateau sloping eastward from the Long Range mountains. The surface exhibits signs of glaciation such as numerous lake basins, ice-sculptured valleys, rounded rock knobs and glacial deposits in typical forms. Reaching a common level of about 2,200 ft., the tablelike summits of the Long Range mountains represent the remnants of an ancient peneplain that has undergone periods of uplift and erosion. Other peneplain surfaces at lower elevations have been recognized. Certain peaks in the Long Range mountains rise above the high peneplain level to elevations of more than 3,000 ft. The Humber is the only major river that crosses the range to reach the west coast. Notable among the eastward-flowing rivers are the Exploits, the Gander and the Terra Nova. In the interior of the island are several long, narrow lakes, the largest of which are the Grand, Red Indian, Gander and Deer lakes. The greatly indented coastline of the island is estimated to be more than 6,000 mi. long. Numerous embayments separated by peninsulas constitute the jagged east and south coasts, in contrast to the relatively straight west coast.

Climate.—In spite of the maritime location of Newfoundland, the climate is essentially continental in character. Air masses which cross Newfoundland come predominantly from the west, bringing the continental influence. Nevertheless, the cold Labrador current that flows southward along the east coast of Newfoundland affects the climate to a certain degree. A cooling effect of the sea in summer prevents especially high temperatures and postpones the warmest weather until August. In winter the presence of the sea moderates the temperature, preventing the very cold readings of mid-continental areas. The mean temperatures in January range from 15° to 25° F. (about −9° to −4° C.), and in July from 50° to 60° F. (10° to about 15° C.). Precipitation is highest, about 50 in., in the southeastern part of the island and decreases northward to about 40 in. at the Strait of Belle Isle. Snowfall ranges from approximately 80 in. along the south coast to more than 120 in. in the northern half of the island. In winter the east and west coasts are icebound for periods of time ranging from five months in the north to one month in the south. Only the south coast is ice-free throughout the winter. Fog occurs frequently along the east coast, especially during the summer months. In fact, the Grand Banks, where the cold Labrador current (*q.v.*) meets the warm Gulf stream, are noted as one of the foggiest areas of the world.

POPULATION AND PRODUCTION CENTRES OF NEWFOUNDLAND

Plant and Animal Life.—Newfoundland lies within the boreal forest region in which coniferous trees predominate. Balsam fir, white spruce, black spruce, white birch and yellow birch are among the most common trees. No more than one-half of the total land surface is forested, while the remainder is mostly rock, barren and bog. The main forest areas lie within the watersheds of the principal rivers. On the barren lands and bogs vegetation is in the form of mosses, lichens, stunted trees, grasses and certain flowering plants.

The island is well endowed with wildlife and fresh-water fish. The chief fur-bearing animals are beaver, muskrat, fox, lynx and otter. Game animals include caribou, moose, black bear and hare. Evidence points to the fact that the numbers of certain game animals are decreasing. Trout and salmon are abundant in the riv

and lakes of Newfoundland and attract sport fishermen from distant cities.

HISTORY

Investigation of the subject of transatlantic navigation suggests that Newfoundland and the Grand Banks fishing ground were well known by fishermen before John Cabot made his voyage in 1497. Cabot gave emphatic advertisement to the wealth of the western waters, an advertisement reinforced by the Portuguese explorer Gaspar Côrte-Real in 1501. By the first quarter of the 16th century, French, Basque, English and Portuguese adventurers were fishing regularly off Newfoundland. (*See* also LABRADOR-UNGAVA.)

The island occupied a vital place in the scientific and military activity of the 16th century; it was associated with the search for the northwest passage, and it was of great strategic importance in the Anglo-Spanish maritime contest. In 1583 Sir Humphrey Gilbert formally annexed Newfoundland for England, and in the course of the next 30 years attempts were made to colonize the island. In 1610 the London and Bristol company established a colony, led by John Guy, at Cupids, on Conception bay. Colonization was attempted also in the Avalon peninsula by Sir William Vaughan, Lord Falkland and Sir George Calvert, later Lord Baltimore. The Baltimore colony at Ferryland promised well, until its proprietors procured the patent for Maryland in 1632. In 1637 all Newfoundland, including the Baltimore holdings, was transferred to Sir David Kirke and his associates. Although the Kirke family seems to have retained possession until the 1670s, efforts at permanent settlement were at an end; 17th century economic theory and practice far preferred the codfisheries to established colonies.

Mercantilism.—Throughout the 16th century the codfisheries attracted great annual expeditions from maritime Europe. In England, these reached the position of supreme national importance. Poole, Bristol, Exeter, Teignmouth and the other western ports became the centres of English enterprise, thus establishing in the Newfoundland trade a dominance that endured for more than two centuries. The cod were shipped overseas, the best fish going to the Mediterranean, the least valuable to the slave plantations in the West Indies. Marketing was done by large merchant vessels which brought to Newfoundland the all-essential salt; in the late autumn they returned to England with wine or oil, or with the more precious bullion from abroad.

In the eyes of the 17th- and 18th-century theorist, these transactions had a double value. First, they made England the beneficiary of the profitable export trade in dried cod. Second, the western fisheries were a great nursery of hardy seamen. It is not surprising, therefore, that the fisheries were regarded as being of fundamental importance to England's security and prosperity. It was manifestly contrary to national policy to permit permanent settlement or to allow the fishermen to winter in Newfoundland. It was equally in the interests of the western merchants to discourage settlement. Accordingly, they adroitly identified their private interests with the widely accepted mercantilist theories, and argued that possession of the fisheries was synonymous with maritime supremacy.

Intensification of maritime rivalry probably forced the issue. In 1662 the French established themselves at Placentia; in 1665 the Dutch burned St. John's, even at that early date a centre of English trade. Beginning with 1696, the French made concerted attempts to conquer Newfoundland with attacks on English establishments in 1697, 1705 and 1708. By the terms of the treaty of Utrecht (1713), the French recognized English sovereignty over Newfoundland, although they retained valuable fishing privileges between Cape Bonavista and Point Riche. These concessions graphically indicate the high value set on the fisheries by both French and English. The ultimate settlement of these claims was postponed for nearly two centuries. During the Seven Years' War (1756–63) Newfoundland again became a centre of conflict, St. John's being lost and retaken by the English in 1762. During the American and French Revolutionary wars, the island's coasts were ravaged again.

The subordination of Newfoundland's social and political development to the codfisheries was complete. After the failure of the early colonization schemes, authority was chaotically exercised by the fishermen themselves, under the title of "fishing admirals." In 1729 an officer of the Royal Navy, Capt. Henry Osborne, was appointed governor. His tenure was seasonal, as was that of his successors until 1817. The naval governors wholeheartedly sought to aid the overseas fisheries as auxiliary to national policy. In 1791 a civil court was instituted and in 1792 a supreme court. In this way the earliest attempt was made to introduce an element of constructive order into Newfoundland affairs.

The population of the island was almost entirely seasonal, the fishermen returning each autumn to England; as late as 1683–84 there were only 120 permanent residents on the island. Throughout the 18th century their numbers increased from 3,400 in 1754 to more than 12,000 in 1774. The newcomers were drawn increasingly from Ireland to provide inexpensive labour for the codfisheries. Food and supplies were brought in from New England. The great prosperity enjoyed by the fisheries in the late 18th century probably accounted for the steady increase in population, which by 1804 reached 20,000. The peak year was 1814–15, when more than 11,000 immigrants arrived in St. John's from southern Ireland.

The operation of the shore fisheries was left chiefly to these newcomers. The prosperous deep-sea fishermen became resident merchants, buying dried cod, fish oil and sealskins for speculation abroad. Their headquarters was St. John's, which became a distributing and financial centre as well as a fishing station. By the end of the 18th century, therefore, the hold of the old system on Newfoundland life was weakening.

Representative and Responsible Government.—As early as 1802 the governor, Lord Gambier, proposed that a form of representative government be granted the colony of Newfoundland. The leading advocates of self-government in the island were William Carson, a politically inclined Scottish physician, and Patrick Morris, an Irish-born merchant. In 1832 representative institutions were established with a bicameral legislature, the lower house of which was elected on a broad franchise. From an early period discord developed between the two houses. The legislative councilors were residents of St. John's and representative of the economically dominant merchants; the assembly was a much more popular body. The discord between the houses led to a temporary suspension of the constitution and amalgamation of the two houses. From 1848 onward, attempts were made for complete responsible government. In 1855 full legislative responsibility was admitted, on the analogy that what had been recognized in Nova Scotia and Canada could not be withheld in Newfoundland.

Economic and Social Development.—Increasing economic maturity underlaid the constitutional changes. The early 19th century was characterized by the growth of the inshore fisheries, as distinct from the bank fisheries. The war years, especially from 1800 to 1815, drastically curtailed the deep-sea fisheries. During the Napoleonic war years the Newfoundlanders established virtual control over the Mediterranean market for dried cod and about 1814 they established an important new market in Brazil. Peace brought a disastrous fall in the price of dried fish, occasioning a prostration in business that lasted until 1819. Thereafter, until the middle of the 19th century, the export of cod remained remarkably constant.

An important adjunct to economic prosperity was the seal fishery. From the middle of the 18th century, the people of the northern bays took a few seals annually by means of nets. Somewhat later, small boats were employed. These ships sailed each spring for "the ice," in order to intercept the great herds of seal on their migrations. In 1831 and 1844 phenomenal catches were made, 686,830 and 685,530 respectively. The industry gave employment to a large number of men and brought handsome returns to the capitalists who directed it. In 1857, 13,600 men shipped for the ice; the catch was valued at $1,700,000. After the middle of the century, sealing declined.

Throughout this period, concerted efforts were made to broaden

the economic basis of island life. Under the direction of Sir John Harvey in the 1840s, agricultural societies were formed in an effort to put farming on a rational and extensive basis. The success of these efforts may be judged by the progressive increase of land under cultivation: 1836, 11,062 ac.; 1845, 29,656 ac.; 1855, 41,108 ac. The majority of such holdings were small, usually being worked as auxiliary to the all-absorbing fisheries. Nevertheless, they did impart a degree of self-sufficiency and permanency to island life. The first geological survey of Newfoundland was begun in 1839 by J. B. Jukes, with the aim of developing mineral resources.

The social development of the colony kept pace with the economic. The merchant class, Newfoundlander by birth and outlook, with the rise of the enterprising Irish shopkeeper, began to lose its exclusively Anglican caste. The outport merchants, with the increasing importance of the seal fishery, played a more decisive role in business life. St. John's was transformed gradually into a commercial centre and colonial capital. In 1800 the population of the city was about 3,000, living along two narrow paths that straggled on the north side of the harbour. A series of disastrous fires in 1816, 1817 and 1819 largely destroyed the ancient malodorous fishing town and made possible a degree of planning. In 1846 another fire hastened this process and opened the way for such improvements as a general water-supply system, the St. John's Water company being incorporated in 1846. In this period, some of the most conspicuous landmarks of St. John's took form. In 1841 the cornerstone of the Roman Catholic cathedral was laid and in 1855 the church was consecrated. In 1843 the building of the Anglican cathedral was begun.

The Newfoundland churches owe their modern organization to the early 19th century. In 1856 the Roman Catholic diocese of St. John's was established. Catholic worship had been conducted regularly as early as 1623 in the Baltimore colony; a prefecture was created in 1784 and a vicariate in 1796. The Anglican diocese of Newfoundland was created in 1839. Provision for Anglican worship was made as early as 1583, and the first Anglican minister reached the island in 1610. The consecration of Bishop Edward Field in 1844 introduced the modern period in church extension and education. Methodism was introduced into Newfoundland in 1764, establishing itself strongly in the northern outposts. In 1855 the Methodist churches joined the Eastern British-American conference, thus breaking the administrative connection with England. The entrance of the Methodist Church into the United Church of Canada was effected in 1925. Organized Presbyterianism dated from 1842. The other chief religious bodies, Salvation Army, Adventists and Pentecostals, came into being later.

The Age of Local Enterprise.—The quarter century 1870–95 was one of general prosperity, attributable to the progressive broadening of economic life through farming and mining and also to the stimulus of railway building. An additional reason was the high price the increasing exports of dried codfish commanded. In an era of general price decline, the price level of dried fish remained almost stationary. Thus the fisherman had the absolute advantage of a high selling price and the relative advantage of greater purchasing power. Moreover, the capitalistic enterprises of the period were locally managed and financed. The intrusion of alien direction and control following 1895 may be regarded as closing one period in Newfoundland history.

The search for economic self-sufficiency was initiated as early as the 1860s. The rapid increase in population (1857, 124,288; 1869, 146,536; 1874, 161,374) gave a note of urgency to these investigations. In 1862 two committees of the legislature examined the fisheries and agriculture, and in 1864 the geological survey of the island was reinstated. Also in this year a copper mine was opened at Tilt Cove on Notre Dame bay. The mine operated almost continuously until 1918 and produced 1,492,000 tons of ore. A number of smaller copper deposits were discovered around Notre Dame bay in succeeding years. Among the producing mines were those at Baie Verte, Betts Cove, Little Bay and Roberts Arm.

Railway construction became the great end of national policy. In 1875 Sir Sandford Fleming, the engineer of the Canadian Pacific, surveyed a practicable route from St. John's to St. Georges bay. In 1880 a joint committee of the legislature recommended the building of a railway northward, as the best means of making accessible the mining and agricultural regions of Notre Dame bay and Exploits valley. In 1881 a company was incorporated and construction begun. The company was aided by government subsidies of $180,000 per annum for 35 years, and a land grant of 5,000 ac. for each completed mile. At the same time, new enterprises were initiated at St. John's. In 1882 a ropewalk was established for the manufacture of fishing gear, netting, cordage and cables, thus freeing Newfoundland from its dependence on foreign sources for these indispensable supplies. Between 1882 and 1884 a large dry dock was constructed. Other industries developed locally included foundries, machine shops and engineering works, all associated with the railway or with shipping.

In the early 1890s two disasters altered completely the pattern of Newfoundland growth. In 1892 three-quarters of St. John's was devastated by fire. The damage to property was computed at $20,000,000, of which less than one-quarter was covered by insurance. In Dec. 1894 the two leading banks, the Commercial and the Union, failed, while the Government Savings bank was compelled to suspend payment. The notes of these banks, the normal currency of the island, became valueless, business stagnated and workingmen were dismissed. As the Union bank was under obligation to provide the half-yearly interest (about $225,000) on the public debt, the crisis assumed serious proportions. A loan from the United Kingdom serving for immediate relief, Newfoundland sought permanent solution by union with Canada. The insistence of the Canadian government on certain debt settlements caused the negotiations to break down early in 1895. Left to their own devices, Newfoundland public men, directed by Sir Robert Bond, succeeded in raising loans in Montreal, New York and London, thus staving off the danger of complete financial collapse.

The bank failures brought to an end a distinct era in Newfoundland history. Local enterprise had been overwhelmed by disaster. The Canadian banks entered the island and their notes replaced the local Newfoundland dollar. Alien direction invaded the business life of the island.

The Era of Foreign Investment.—For the first 30 years of the 20th century, Newfoundland development followed a consistent pattern. Foreign enterprise increasingly sought to exploit the island's natural resources. World War I intensified this process. The liquidation of long-standing differences with France and the United States was a feature of this period.

As early as the 1890s, foreign investment was attracted to railway construction and mining. Sir Robert Reid of Montreal, a Scottish-Canadian promoter, had become influential in pushing the construction of the transinsular railway. The financial disaster of 1894–95 induced the government in 1899 to transfer to Reid virtually all the island's communications; railway, shipping lines and telegraph, as well as the St. John's dry dock and extensive timber and mining rights. Strong protest produced an amendment of the contract in 1901, whereby the more objectionable monopolistic features were surrendered at the price of about $2,500,000. Construction was pushed vigorously; in 1893 the railway reached Norris Arm on the Exploits; in 1897, Port aux Basques. Fast steamships were put in service between this point and Sydney, N.S. The profitable operation of these enterprises proved increasingly difficult, until finally in 1923 the government assumed their operation.

In 1895 the exploitation by a Canadian company of the iron deposits on Bell Island commenced and in 1905 the Anglo-Newfoundland Development company was constituted for the manufacture of newsprint. The company was originated by Lord Northcliffe, who wished to make his chain of newspapers independent of foreign countries for supplies of newsprint. The location of the original plant was at Grand Falls, where the company received power rights on the Exploits river and timber limits amounting to 2,000 sq.mi. The first paper was produced in 190[illegible]. For export purposes the company installed docks and sheds at Bo[illegible]

wood, which was connected with Grand Falls by private railway. The company expanded greatly. In 1923 it acquired the pulp mill of the Albert Reed company at Bishop's Falls. In carrying out surveys, officials of the company discovered outcroppings of copper-lead-zinc ore near Buchans but it was not until 1925 that these deposits were made profitably exploitable. The American Smelting and Refining company undertook development under agreement with the Anglo-Newfoundland Development company, and mining operations were begun in 1927.

The participation of Newfoundland in World War I was distinctive. The large seafaring population enlisted in the Royal Naval reserve, an institution of long standing on the island. In all, over 1,500 men served at sea in all parts of the world. In Aug. 1914 the government determined to raise a small land force, ultimately known as the Royal Newfoundland regiment. This unit fought in Egypt, the Dardanelles and France. At the battle of Beaumont Hamel, in the Somme (June 30, 1916), it lost virtually its entire complement of 700 men. The regiment was immediately brought up to strength and served with distinction during the later phases of the war. In 1917 a forestry corps was recruited from among Newfoundland woodmen. A noncombat unit, it was employed in timber cutting in Scotland. Outside these purely Newfoundland formations there was extensive enlistment in the British forces.

In the era following World War I came the exploitation of the timber resources of the west coast. Between 1923 and 1925 the Newfoundland Power and Paper company built a paper mill at Corner Brook and a hydroelectric plant at Deer Lake. Costs of construction were more than double the original estimates and the company decided to sell its interests to the International Paper company in 1928. Bowaters Newfoundland corporation acquired the plants in 1937 and greatly expanded the production facilities.

Labrador Coast Award.—This decision was rendered in 1927 by the judicial committee of the imperial privy council of Great Britain following litigation between Newfoundland and Canada over ownership of the ill-defined area of Labrador. The waters off the Labrador coasts were worked by French and English fishermen, the former from Canada, the latter from Newfoundland. With the cession of Canada to Britain in 1763 by the treaty of Paris, disputes over the title to Labrador were referred to British tribunals. These were concerned primarily with the coastal areas, since until the late 19th century there was no economic attraction except fishing.

Between 1763 and 1825, four adjustments were made, the sum of which gave the Newfoundland colony jurisdiction over the Atlantic face of Labrador and Canada the north shore of the Gulf of St. Lawrence. In 1888 the exact location of the inland boundary was first disputed. The decision of the judicial committee in 1927 was in favour of Newfoundland, asserting that "the Coast of Labrador" included the hinterland to the watershed of the rivers draining eastward to the Atlantic. The award endowed Newfoundland with a continental dependency of 110,000 sq.mi., embracing among other assets the basin of the Hamilton river, and stretching from the Gulf of St. Lawrence to Cape Chidley.

Commission of Government.—In 1931 Newfoundland began to experience the effects of the world depression. These were intensified by the heavy service charges on the Newfoundland debt. Throughout the 1920s, the program of railway consolidation and highway construction, along with increased aid to education, raised the national debt from $43,000,000 to $101,000,000. Moreover, the budgets had not been balanced after 1920, the annual deficits amounting to an average of $2,000,000. The deficits were met by loans, which, of course, added to the general indebtedness. The onset of the depression, therefore, found Newfoundland in a dangerous position. Unfortunately, Newfoundland's best customers for newsprint, minerals and dried cod were themselves seriously affected. Employment declined in Canada and the United States, forcing home scores of seasonal workers. In 1931 a loan for $8,000,000 received no tenders. Upon request, a financial adviser for the government was dispatched from the United Kingdom. In 1932 loans were successfully raised from the Canadian banks and from local subscriptions. Drastic cuts were made in expenditures and taxes steeply increased. During 1933, however, no improvement was visible, and additional loans were sought from governments of Canada and the United Kingdom. At this time application was made for the appointment of a royal commission to inquire into Newfoundland affairs.

In February a royal commission was appointed. It consisted of three members, a Newfoundlander, a Canadian and a representative from the United Kingdom. The terms of reference stressed the examination of Newfoundland's financial situation and prospects. The royal commission met throughout the summer of 1933, gathering information on Newfoundland life. A report of these investigations, along with certain recommendations, was published in the autumn of 1933.

The report was a comprehensive document, containing an extensive survey of Newfoundland's existing condition and past history. The ills of the dominion were set down to the functionings of a perverted parliamentary system which had been exploited for party and personal gain. As a solution the royal commission recommended the temporary suspension of government responsible to the people. It recommended, also, that the government of the United Kingdom assist Newfoundland financially until such time as the dominion became self-supporting. Other recommendations concerned the rehabilitation of the fisheries, the revision of the educational system and so on. The constitutional proposals were startling since they envisaged the establishment of a unique body, the commission of government, which should exercise both legislative and executive functions.

The commission of government took office in Feb. 1934 and governed Newfoundland until union with Canada in March 1949. It was composed of six appointed members, three Newfoundlanders and three from the United Kingdom, under the chairmanship of the governor. The commission encountered a number of difficulties, virtually all of which proceeded from the low prices commanded by the island's primary products in the world market. The commission gave assistance to the fishing industry by creating a fisheries board, which made substantial progress in improving standards of production and methods of marketing. Aid was also given in building more modern fishing vessels. Other undertakings that enjoyed the commission's support were farming and land settlement, the former through education and cash bonuses, the latter by means of the land settlement board, later the department of rural reconstruction. Transportation was improved: the main line of the railway was restored to predepression standards, several new coastal steamers were put in service and a number of local roads were laid out. Expenditures were substantially increased in education and in health. The means of implementing these reforms came from improved finances. The commission simplified and reduced the customs duties (the traditional staple income of Newfoundland), and by thus encouraging imports secured substantial increases in revenue. It was also assisted by grants-in-aid from the United Kingdom to cover ordinary expenditures, and loans from the Colonial Development fund for capital outlays. In terms of rehabilitation and reform, the record of the commission of government was impressive.

World War II.—The outbreak of war in Sept. 1939 found Newfoundland without fixed defenses of any kind, and without even a garrison. A local defense force, the Newfoundland regiment, was immediately raised, and troops were recruited also for overseas service. The latter formed part of the British army, not, as in World War I, a separate Newfoundland unit. The island provided the personnel of two heavy artillery regiments, one of which later became a field artillery regiment. They served in north Africa, Italy and western Europe. A total of 2,327 Newfoundlanders joined these units. A Newfoundland overseas forestry battalion, a civilian organization, was likewise raised, with a strength of about 1,500 men. Individual Newfoundlanders, both men and women, enlisted in the Canadian as well as in the British forces. Total enlistments were about 10,000.

The military collapse in western Europe in the summer of 1940 precipitated a crisis in Newfoundland. The security of the island was vital not only to Newfoundlanders themselves but to all North America. In June 1940 Canadian troops undertook the ground protection of Gander airport and the Botwood seaplane

base. Two months later Canada assumed wide responsibilities for the defense of Newfoundland, both on the ground and in the air. The Canadian navy constructed and maintained a large base at St. John's. The United States also had a stake in the defense of Newfoundland. In virtue of the "base agreement" with Britain, the United States secured leases on three areas, where it established bases. Newfoundland served as an important point of departure for aircraft and surface convoys throughout the war.

World War II had a profound effect on the island economy. Newfoundland products were in steady demand at high prices. Jobs were easy to secure. War prosperity extended even into remote areas, drawing young men and women into employment elsewhere, principally in construction work at military bases. As early as 1941, the commission of government reported a surplus of revenue over expenditure, the first since 1919. As a result of this and of successive surpluses, the commission was able to extend to the United Kingdom an interest-free loan of $12,000,000. By March 1948 a cumulative surplus of $30,000,000, including the British loan, was built up.

Confederation With Canada.—The ending of the war raised the subject of constitutional status. In Dec. 1945 the government of the United Kingdom announced that a national convention would be elected to secure a representative view of what Newfoundlanders desired. The convention was elected in June 1946 and began its deliberations in September. Delegations were sent to London to ascertain British views and to Ottawa to sound out Canada on terms of union. A motion to send a similar delegation to Washington, D.C., was decisively defeated. The formal reply of the Canadian government was made in Nov. 1947. Nevertheless, in preparing the ballot, the convention recommended only two choices, continuation of the commission or restoration of responsible government. The government of the United Kingdom, however, insisted on adding to the ballot union with Canada. The first poll, held in June 1948, resulted in stalemate; no one of the choices received an absolute majority: responsible government received 69,400 votes, union with Canada 64,066, commission of government 22,311. A second poll, held on July 22, produced a majority of 78,823 votes in favour of union with Canada against 71,334 for responsible government. Representatives from Newfoundland went to Ottawa to discuss confederation.

The term confederation has an especial historical significance. Twice before, 1869 and 1895, Newfoundland and Canada had negotiated confederation. The first confederation effort was part of the general move to unite the British American colonies. Newfoundland had been represented at the Quebec conference of 1864, which drafted the plan of the original confederation. It was not until 1869, two years after the passage of the British North America act, that a decisive move was made in Newfoundland and then the proposal was rejected. The second attempt to bring about confederation, in 1895, was the direct outcome of economic tensions, culminating in the Newfoundland bank failures of Dec. 1894. Negotiations were begun in April, but broke down on the financial terms Canada was prepared to offer. Although both parties were anxious to make concessions, a gap of $200,000 remained between what Canada could extend and Newfoundland accept. This small sum wrecked the second confederation proposals, leaving among Newfoundlanders a sense of continued resentment.

Confederation discussions in 1948 extended over two months and produced a statement of the terms of union. Basically, these terms were the acceptance of provincial status by Newfoundland and the assumption by Canada of services normally provided for the other provinces, including the payment of stated annual subsidies. As in the instance of the other provinces, Newfoundland was to be represented in the federal parliament, with seven members in the commons, and six in the senate. The terms also provided for the revival of the provincial constitution, suspended during the operations of the special commission of government. In place of the bicameral parliament of responsible government days, however, a single-chamber legislature composed of 28 members was envisaged.

In a different category was the taking over by the federal government of the Newfoundland railway (and shipping services) and the sterling debt. amounting to about $63,000,000. Canada agreed to make special transitional grants for a limited period and to leave to Newfoundland the surpluses amassed during World War II. Finally, Canada agreed to appoint within eight years a royal commission to review Newfoundland's economic position and to make recommendations. These special features of the terms of union were in recognition of Newfoundland's unique position, economically as well as constitutionally.

The eight-year period having elapsed, a royal commission on Newfoundland finances was constituted, and submitted its report in May 1958. The commission recommended that Newfoundland thereafter be granted additional financial assistance of $8,000,000 per annum.

THE PEOPLE AND POPULATION

The population of Newfoundland illustrates the interplay of history and environment. The people are markedly homogeneous, over 90% being of English and Irish origin. Until the beginning of the 19th century the population was small, but thereafter it increased rapidly. The 1951 census placed it at 361,416, of which 7,890 lived in Labrador; the 1961 census set the total at 457,853 of which 13,534 lived in Labrador. Of this total about 98% was native born. Emigration is an established pattern, especially for young persons. Between 1891 and 1961 it is believed that more than 80,000 persons emigrated.

Incorporated Places of 5,000 or More Population (1961 Census)

Place	Population				
	1961	1956	1951	1945	1931
Total province	457,853	415,074	361,416	321,819	263,033
Corner Brook*	25,185	23,225	—	—	—
Gander	5,725	1,289	—	—	—
St. John's	63,633	57,078	52,873	44,603	36,444
Stephenville	6,043	3,762	—	—	—
Wabana	8,026	7,873	6,460	—	—
Windsor	5,505	4,520	3,674	—	—

*Previously known as Corner Brook East, Corner Brook West, Curling and Humbermouth.

Note: Populations reflect data as each place was constituted at date of each census. A dash (—) indicates place did not exist during reported census, or data not available.

The early supremacy of the codfishery determined the location of settlement in the island. Convenience to the inshore grounds or to the more distant banks were decisive factors, as were shelter for boats and space for the stages required for curing fish. Thus the population became widely scattered along the 6,000 mi. of coast. However, the Avalon peninsula was recognized as particularly desirable for settlement in relation to the Grand Banks fishery. To this day more than 40% of the island's population lives on this peninsula and about 20% lives in greater St. John's. During the 20th century population on the west and north coasts of the island increased more rapidly than on the south and southeast coasts. The bulk of the population still lives in about 1,300 small coastal settlements, almost 90% of which have fewer than 500 inhabitants. Strong attempts have been made by the government to encourage the abandonment of small, isolated settlements. Financial assistance has been offered to move family belongings to more suitable locations and in many cases wooden houses have been floated from small islands to mainland settlements. That progress along these lines has been achieved is indicated by census figures. The percentage of the population living in communities of over 1,000 increased from 34% in 1945 to 51% in 1961.

The smallness and scattering of the population have influenced the Newfoundland character. Isolation bred individuality and self-sufficiency, but it also extracted a heavy toll. Customs changed slowly; 16th-century methods of fishing and fish-curing persisted; new ideas were rare and were resented; there was a marked weakness in co-operation, individualism of the most uncompromising sort having been nurtured on long years of near self-subsistence.

The church plays a very important role in the Newfoundland community. Denominationally, the population is divided into three main groups, about one-third Roman Catholic, nearly one-third Anglican and about one-quarter United Church. The

remainder of the population is divided among several other denominations, the largest of which is the Salvation Army. Since one denomination frequently monopolizes an entire community, the church is a potential political force. This factor is tacitly admitted in political and administrative circles where efforts are bent toward maintaining a balance in denominational representation.

Two special characteristics of the islanders merit attention, the imagination and humour displayed in naming their numerous communities, and the marked poetic gifts possessed by many of them. Such place names as Heart's Delight and Heart's Content reflect feelings associated with the area; and indicative of isolation, Come by Chance. Nautical or navigational inspiration appears in Main Topsail (mountain peak), Pushthrough and Little Tickle (a tickle is a very narrow strait). Port aux Basques, Frenchman's Bay and Ireland's Eye recall the various nationalities long ago associated with the island. Poetry appears to be a natural medium of expression and has produced a growing body of published work. E. J. Pratt, a Newfoundlander, ranks among leading Canadian poets (*see* CANADIAN LITERATURE [ENGLISH]).

On a more popular level, sea chanties and folk songs are characteristic of the island. Many of these are traditional, the inheritance of an English or Irish past; others reflect the day-to-day life of the fisherfolk, often told with grotesque exaggerations. One of the most popular of Newfoundland songs is entirely modern, Arthur Scammell's "Squid Jiggin' Ground."

GOVERNMENT AND FINANCE

The provincial government of Newfoundland has jurisdiction over education, crown lands and forests, municipal government, property and civil rights, and other matters assigned to the provinces by the British North America act. The house of assembly consists of 42 members (previously 36) elected for a period of not more than five years. The Liberal party under the leadership of the premier, J. R. Smallwood, was victorious in the first election after confederation in 1949 and in 1962 maintained its majority position for the fifth consecutive time. The Progressive Conservative party functioned as the official opposition.

After confederation the economic policy of the provincial government was one of energetic expansion. On taking office for the first time, Smallwood assumed the portfolio of economic development along with the premiership. Thus he clearly showed his appreciation of the predicament of Newfoundland—considerable potential wealth but small immediate resources and a small and scattered population. The general level of prosperity in Newfoundland has long been lower than that prevailing in the Maritime provinces (New Brunswick, Nova Scotia and Prince Edward Island). It was the declared aim of the provincial government to raise Newfoundland living standards to a level comparable with standards in these sister provinces. The federal government also recognized this lack of comparability of living standards and provided annual transitional grants to strengthen provincial revenue. These grants were reduced from year to year toward their eventual termination in 1962. A permanent annual grant of $8,000,000 to maintain public services at the level achieved in 1958 was recommended by the Royal Commission on Newfoundland Finances.

The two major aspects of economic policy were the further development of natural resources and the encouragement of industrialization. With respect to natural resources the government itself undertook mineral surveys both on the island and in Labrador through the agency of the Newfoundland Labrador corporation. Under an agreement made with the government the British Newfoundland corporation, an Anglo-Canadian syndicate, received mineral, timber and hydroelectric power rights on 50,000 sq.mi. in Labrador and 10,000 sq.mi. on the island. The company agreed to spend large sums of money annually on explorations. Direct investment by the government was involved in the industrialization program. Local industries were aided financially and new industries were established. Also, European interests were offered assistance in establishing industries in Newfoundland. Among the new industries brought into production were cement and gypsum wallboard plants, a shoe factory, a rubber products plant and a cotton textile mill. Some were successful while others were not, but the net result was an expansion of employment opportunities.

EDUCATION

The Newfoundland educational system is denominational in character. The first school was set up at Bonavista in 1726 by the Society for the Propagation of the Gospel, the Church of England missionary organization. Schools for Roman Catholics were supplied by the Benevolent Irish society. The Education act of 1876 formally recognized the denominational principle by accepting Roman Catholic, Anglican and Methodist schools and by dividing the government grant to education on a proportional basis. Successive amendments to the act did not substantially alter this arrangement, the appearance of the Salvation Army, Seventh-Day Adventists and Pentecostals being marked by schools conducted by those bodies on the same basis as those of the older churches. By the 1950s there were also 33 nondenominational schools. All classes of schools are subject to the same regulations, follow the same curriculum and receive provincial grants on the same basis.

In 1925 Memorial University college at St. John's was opened as a permanent memorial to the Newfoundlanders who served in World War I. In the 1925–50 period the university gave courses in the first two years of arts and pure sciences and in the first three years of engineering, provided teacher training and sponsored an active adult education program. In 1950 the college was expanded into Memorial University of Newfoundland with degree-granting authority.

The International Grenfell association carries on important educational and medical work in the northern outports and on the Labrador coast. Commenced in 1892 by Sir Wilfred Grenfell (*q.v.*), the association maintains a number of schools and hospitals and an orphanage.

PRODUCTION

The Newfoundland economy is based largely on primary industries. Certain primary products are manufactured for export, while others are marketed essentially in the raw state. Hydroelectric plants produce the only source of energy available on the island, while coal and petroleum are imported for additional energy and heating requirements. Historically, fishery products have been the mainstay of the economy and until the end of the 19th century provided as much as 90% of the exports. Mining developed gradually during the 20th century and the utilization of forest resources on a large scale did not occur until after World War I. The economy is strongly dependent upon external trade because most of the requirements of the population must be imported, and to balance these imports a high level of exports must be maintained.

Agriculture.—Agriculture in Newfoundland is subsidiary to other primary industries. Production is chiefly for domestic consumption and a large part of the farming activity is carried on by fishermen and forest workers on a part-time basis. The basic reasons for the relatively backward condition of agriculture are the unsuitability of climate and the scarcity of good soils. Although winter temperatures are not so low as they are in the main agricultural areas of Canada, spring arrives late, the growing season is short and there is risk of frost during the growing season. There is no large, continuous area suitable for cultivation; for the most part soil exists in depth only in river valleys or in pockets near the coast, and where it does exist in depth it often suffers from poor natural drainage.

Agriculture is best developed along the west coast near St. George's, in the Humber valley near Corner Brook, and on the Avalon peninsula, especially near St. John's. Dairy farms are found near most of the large towns on the island. Outside these areas, commercial farming is almost nonexistent and agriculture is carried on chiefly in kitchen gardens. In connection with gardening, the numerous part-time farmers generally keep a cow, a few sheep or goats and some chickens. Hay and pasture land constitutes over half of Newfoundland's arable acreage, but addi-

tional feed must be imported. Oats, the principal grain crop, is usually cut green for fodder because grain seldom matures properly, except on the west coast. The most common vegetables grown are potatoes, turnips, cabbages, carrots, parsnips and beets.

Successive governments have attempted to stimulate farming. The commission of government began a land settlement scheme in 1934 to provide employment for families on relief. These settlements, comprising several hundred families established in eight different localities, met with little permanent success. A demonstration farm was established near St. John's, where students were given practical instruction in crop production and livestock raising. A soil survey program was actively pursued with the aim of opening new agricultural land. After World War II a settlement scheme for veterans was undertaken in the upper Humber valley. In the second half of the 20th century the possibility of economically draining the extensive flat bogs of Newfoundland promised a moderate expansion of agriculture. Tests have been conducted on the Avalon peninsula to prove the efficiency of growing large quantities of hay for beef cattle. Expansion may take place also in the growing of blueberries, which are frozen and shipped to the U.S. market in considerable quantity. The government-sponsored rural-electrification program in the 1960s brought electricity to many communities for the first time.

Forestry.—Forests on the island of Newfoundland constitute about 35% of the total area. The major products based on these forest resources are pulp and paper, chiefly newsprint. Forest industries at mid-20th century contributed about 32% of the total Newfoundland income. There are two large pulp and paper mills in the province, which develop their own hydroelectric power near their mill operations. The location of the pulp and paper mills at or near tidewater gives them transportational advantages that make them fully competitive in the world market. Virtually all of their production is exported to foreign countries. A detailed study of the forest industries was made in 1955 by a government-appointed royal commission. The report indicated that there remained on the island and in Labrador sufficient untapped reserves of timber to supply a third pulp and paper mill with a capacity of about 500 tons a day.

The production of lumber is carried on in more than 600 small sawmills scattered throughout the island. Most of the lumber is roughly finished for local consumption. Several other small industries are based on forest resources. Among these are producers of fiberboard, flooring, plywood and furniture.

Mining.—The mineral industries, based on a comparatively few producing mines, accounted for approximately 13% of the Newfoundland income at mid-20th century.

Iron ore is mined at Bell Island. Part of the ore moves to Sydney, N.S., where steel is produced, and the rest is exported. Zinc, lead, copper and small quantities of gold and silver are produced at Buchans. The ore is concentrated at the mine site but is sent to export markets for refining. Most of Canada's fluorspar is mined at St. Lawrence on the Burin peninsula. The fluorspar is shipped to Arvida, Que., for use as a flux in producing aluminum, and to export markets. Copper is mined at Little Bay and an old copper mine at Tilt Cove on the northeast coast has been reopened and brought back into production for the first time in 36 years.

Limestone is actively mined at several places. The quarry at Aguathuna on the west coast ships limestone to Sydney where it is used as a flux in the iron and steel industry. In the vicinity of Corner Brook, limestone is quarried to supply the cement plant. From a quarry at Cobb's Arm in Notre Dame bay limestone is shipped to Botwood and St. John's. Gypsum is mined on the west coast at Flat Bay for the manufacture of wallboard at the Corner Brook plant. There are several mineral prospects on the island, such as the asbestos deposits at Baie Verte, and their development was accelerated in the 1960s.

Development of the immense reserves of iron ore in Labrador began after World War II. A railway line was completed in 1954 from Sept Îles to the ore fields. The Twin Falls power development project to provide power for the Wabush and Carol lakes iron projects began production in 1961 and the first open-pit iron mine was opened at the Carol project in 1962.

Fisheries.—Among the primary industries the fishery has declined in value relative to the others, but still constitutes a major source of income for Newfoundland. The main products are dried salt codfish and frozen filleted fish of various species. Inshore fishing is mainly concentrated along the northeast coast, and codfish is the principal species caught. Bank fishing with larger vessels, chiefly draggers, is carried on from settlements on the northeast and south coasts. By this method of fishing a number of species are obtained, including cod, haddock, halibut, flounder and rosefish.

Lobsters are procured on all coasts of the island, but are most abundant along the west coast. The herring fishery is concentrated in the Bay of Islands-Port au Port bay area on the west coast and in Fortune bay on the south coast. Salmon occurs in all Newfoundland waters and, although not plentiful, it is fished in many areas for a minor source of income.

Various fishery products are processed for market in different ways. Part of the catch of codfish is salted and dried artificially or in the sun, and the rest is fast-frozen in filleting plants. Many of the other species except salmon and herring are also fast-frozen. The salmon is sold fresh-chilled or canned and most of the herring is pickled. The frozen filleted fish is exported to the United States, while the dried salt codfish is shipped to various European and West Indian markets. Because the markets for dried fish appear capable of greater expansion in the near future than the markets for frozen fish, the emphasis in Newfoundland is on the construction of artificial drying plants rather than freezing plants. There is no shortage of fish resources and the industry may expand its production under more modern and efficient methods of catching and processing the fish.

COMMUNICATIONS

Water transportation has long been of utmost importance in linking the hundreds of small Newfoundland settlements. The Canadian National railways' coastal steamship fleet serves the larger trade centres and the isolated communities on all three coasts. Several scheduled shipping services connect St. John's and Corner Brook with various mainland and overseas ports. A daily ferry service across Cabot strait is operated by the Canadian National railways as part of the railway system.

The main line of the narrow gauge railway runs from Channel-Port aux Basques on the west coast, through Corner Brook, Grand Falls, and Gander to St. John's on the east coast. Branch lines connect Lewisporte, Bonavista, Carbonear and Argentia with the main line. The whole system totals a little more than 700 mi. of track. The Trans-Canada highway follows a route similar to that of the railway. Much of the highway is gravel-surfaced, but all will be paved in the final construction stage. The road network of Newfoundland is still rather rudimentary. In the early 1960s there existed only 400 mi. of paved highway on the island. Nevertheless, road construction has been vigorously pursued and most of the larger settlements can be reached by land transportation. Frequent airline service is provided between the mainland and St. John's, Gander and Stephenville and between St. John's, the Burin peninsula and St. Pierre Island.

The Canadian National telegraphs serve nearly all of Newfoundland's scattered settlements, far more than are served by telephone. Several independent telephone companies provide service within the more populated areas. About 75% of the island's population has telephone service available. Newfoundland is the landing place of more than a dozen transatlantic cables.

Radio and television services are provided chiefly by the Canadian Broadcasting corporation. This publicly owned system operates radio stations in St. John's, Gander, Grand Falls and Corner Brook. In co-operation with the United States armed forces the corporation operates television stations at Stephenville and at Goose Bay, Labrador. In addition, there are several privately owned radio and television stations. A satellite-tracking station operated in connection with the U.S. space exploration program was opened near St. John's in 1961.

(J I. C.; G. TR., C CY.; C. N. F.)

NEW GUINEA, the world's largest island after Greenland, stands on the Sahul shelf, a northward submarine extension of the Australian continent. Its total area is 299,310 sq.mi.; 338,878 sq.mi. excluding islands administratively attached to political units on the island. At its nearest point the island is only 100 mi. from the Australian mainland. Political control of New Guinea was divided between Australia and the Netherlands until 1962, the boundary being the meridian of 141° E., except for a short section in the south along the Fly river.

The western portion of the island, forming the Dutch colony Netherlands New Guinea, had been claimed by the Indonesian republic ever since the latter's creation in 1949. By agreement (Aug. 15, 1962) between the Netherlands and the Indonesian republic, negotiated through the United Nations, administrative authority over this territory, known to the Indonesians as Irian Barat (West Irian), was transferred to Indonesia on May 1, 1963 (see *History: West New Guinea* below). Eastern New Guinea comprises the territory of Papua and the trust territory of New Guinea, both administered by Australia. West New Guinea includes the Schouten Islands, Japen Islands, Raja Ampat Islands and Salawati Island. Papua territory includes the D'Entrecasteaux Islands and the Louisiade archipelago (*qq.v.*) and the Trobriand Islands; New Guinea trust territory includes the Admiralty Islands, New Ireland, New Britain and Bougainville (*qq.v.*) and Buka.

PHYSICAL GEOGRAPHY

Geology.—The geological structure of New Guinea is complex and little known. According to the Dutch geologist R. W. van Bemmelen, the island forms part of a great circum-Australia mountain system, traceable southeastward through the Solomon Islands and New Zealand. Other geologists have detected a similarity with the threefold structure of the Indian subcontinent, in which the central mountain complex of New Guinea resembles the Himalayas, and the Digoel-Fly lowland the Indo-Gangetic plain, while the rigid Deccan plateau finds its counterpart in the Australian continent. Little is known about the pre-Tertiary history of the island. Paleozoic rocks occur in parts of the central mountain system of western New Guinea but large areas are occupied by relatively young rocks overlying a pre-Tertiary basement complex which is exposed in the cores of many of the mountain systems. Van Bemmelen regards the metamorphic rocks of Japen Island in Geelvink bay and of the Cyclop (or Cyclops) mountains as remnants of an old Melanesian continent to the north, sediments from which were deposited in a great geosyncline which occupied much of New Guinea from Silurian to mid-Tertiary times. This long period of subsidence was interrupted by a number of orogenic movements and the intrusion of plutonic rocks. Highly metamorphosed rocks associated with these intrusions occur over large areas of the central mountain complex, in the Owen Stanley range and in the Northern ranges (or Northern Dividing range, including the Van Rees range and the Foja range), but these rocks were already intensely deformed before the plutonic intrusions occurred. The present vigorous relief of much of the central and eastern portions is largely the result of intense orogenic movements which, beginning in the Oligocene, extended into the Pleistocene.

Much of the central portion of the island and the entire eastern "tail" is occupied by a remarkable mountain system. Secondary and Tertiary rocks are folded in an east-west, or east-southeast to west-northwest direction. There is no evidence of overthrust or nappe structures and the main movements appear to have been vertical; folding appears to have been secondary to the raising up of the old pre-Tertiary basement complex. The central mountain system is a great horstlike structure with upturned edges and abrupt step-faulted margins to the north and south, the latter being extremely precipitous. The Northern ranges, which are separated from the central mountain system by a broad depression of Tertiary deposits thickly overlain by alluvium, reveal a somewhat similar structure in which the pre-Tertiary basement is exposed; it is bordered on the north by another east-west depression which reaches the sea on either side of the fault-bounded Cyclop mountains. To the south the Digoel-Fly lowland, regarded by T. W. Edgeworth David as the main axis of the depression, is a low dissected plateau sloping southward from the central mountain system, in which the rivers have cut wide valleys. Farther south the pre-Tertiary basement appears in a number of low hills near Merauke, marking in Van Bemmelen's opinion the margin of the Australian continent.

The eastern "tail" differs from the central mountains in having been much more actively volcanic in the geologically recent past and it still contains a number of active volcanoes. Active volcanism is also present in a chain of islands off the northern coast curving eastward into New Britain and New Ireland. Widespread coral limestones occur in many outlying islands off the northeast coast.

The western peninsula, the Vogelkop or Bird's Head, by contrast consists of lightly folded Tertiary rocks, more strongly folded in the low northern mountains where the pre-Tertiary basement again appears. Along the north coast is a zone of recent volcanism, a continuation of the volcanic arc of the Indonesian island of Halmahera in the Moluccas, which contains the volcano Umsini in the Arfak mountains.

Physiography.—Three major divisions of the island can be distinguished, each containing several structural elements; these are generally topographically continuous from one division to another, although their structural relations are far from clear. The Vogelkop is almost completely cut off from the mainland by the shallow Teloek Beraoe (McCluer gulf); to the north is a mountain complex. An extensive lowland borders the gulf and a narrow neck of mountains connects with the Northern ranges and the Snow mountains in the body of the island. Other isolated mountains appear in the Bombarai peninsula to the south of the gulf. The trend of the northern Vogelkop mountains is continued in the island of Japen in Geelvink bay and isolated mountains along the north coast (Cyclop mountains).

Elsewhere the north coast of the body of the island is bordered by a plain, rising southward to the complex Northern ranges; the ranges east of Sepik river constitute a topographic continuation. South of the Northern ranges lies a great median depression, the so-called Lake plain (Meervlakte), occupied by the Rouffaer and Idenburg rivers, tributaries of the Mamberamo which flows to the north coast; a low sill separates this zone from the similar extensive lowland of the Sepik river. To the south of this median depression is a great mountainous zone about 100 mi. in breadth and still little known. It consists of a series of ranges trending roughly east to west and arranged in echelon formation. These include the Nassau and Orange (Oranje) ranges, forming the Snow mountains, which are continued eastward in the Star (Sterren) and Digoel ranges and, in the Australian-administered territories, in the Hindenburg, Victor Emanuel, Muller and Bismarck ranges. The headstreams of the Digoel river and Fly river have carved great gorges through several ranges, many of which rise above 10,000 ft. Much of the Snow mountains lies above 12,000 ft., and the system rises above the snow line (about 14,500 ft.) in a number of great peaks. Carstensz top (16,535 ft.) is the highest point in the whole of the southwest Pacific; it was climbed in 1937 by the A. H. Colijn expedition which approached from the south. The crest of the system lies on the southern side and there is a series of precipitous drops to the alluvial lowlands of the southern coast. Eastward the foothill zone becomes broader, and in western Papua it is punctuated by a number of ancient volcanic

mountains; one of these extinct volcanoes, Mt. Bosavi (Besavi) rises to 9,500 ft. To the south the Digoel and Fly rivers flood enormous areas during the period from October to April. The Fly river is actively building up its delta.

The tail is marked by a change of trend of the main structural elements. Volcanic activity reappears in a string of islands off the north coast, and is continued through the "Rabaul arc" and into the Bismarck archipelago. Ranges east of the Sepik and in the Huon peninsula, together with the Ramu and Markham valleys, continue the topographic features of the northern portion of the main body. Near Mt. Hagen the central cordillera system becomes narrower and is penetrated by several broad valleys, but it broadens eastward in the Bismarck range of the trust territory, where Mt. Wilhelm (15,400 ft.) also rises above the snow line. The foothill zone to the south reaches the coast at the head of the Gulf of Papua, and to the east the Owen Stanley range (Mt. Albert Edward, 13,100 ft.) takes up most of the tail, but along the Port Moresby coast there are numerous small and swampy coastal plains. About 148° E., the west-northwest to east-southeast direction is resumed, and the transition is marked by further volcanic activity. In 1951 a pelean eruption (*see* VOLCANO) of Mt. Lamington (5,850 ft.) caused much loss of life. Volcanicity continues in the D'Entrecasteaux Islands and in Buka and Bougainville islands.

Climate and Soils.—New Guinea experiences the uniformly hot and humid climate of equatorial regions, but elevation produces a marked lowering of temperature, and the highlands have a much modified climate. Rainfall is heavy, only a small part receiving less than 60 in. annually. On the north coast precipitation is generally about 100 in., but many places receive much more. November–April is the season of the northwest monsoon, which brings heavy rain to all parts and especially to the north coast of New Guinea and the Bismarck archipelago. May–October is the season of the southeast trades, which bring torrential rain to the south coasts of New Britain and New Ireland, and those parts of the main island that stand athwart the winds. In the Merauke district of western New Guinea and in the vicinity of Port Moresby the period of the southeast trades is a dry season; Merauke receives about 60 in. annually and Port Moresby only 40 in., though precipitation increases rapidly to east and west.

Temperatures at lowland stations fluctuate slightly around the 27° C. (80° F.) mark throughout the year; the annual range is seldom more than about 8° C. (15° F.) and is less than the diurnal range. Stations on the northern coasts show a typical equatorial regime with temperature maxima following the equinoxes; temperatures in March or April and in October or November average around 27.8° C. (82° F.) falling to around 26.7° C. (80° F.) in July and January. On the south coast, where there is a pronounced dry season, the annual range is greater; the highest mean monthly temperatures are recorded in December and January, attaining 27.8° C. (82° F.), and the lowest in June and July when they fall to about 25.6° C. (78° F.). The daily range is also greater on the south coast, particularly during the dry season.

Under the continuously high temperature and the heavy, well-distributed rainfall, the soils are badly leached and offer limited opportunities for agriculture. Coastal soils are often too sandy or coralline. The best soils are those of the volcanic areas, the Gazelle peninsula of northeastern New Britain being outstanding.

Vegetation.—The natural vegetation of New Guinea comprises a great wealth of plant species, and much of the island is still botanically unexplored. Vestiges of the eucalyptus vegetation of Australia are found in parts of southern Papua, but Indo-Malayan elements are generally dominant. More than two-thirds of the island is forested. Lowland rain forest occurs widely below 6,000 ft.: it exhibits the typical multistory development of equatorial rain forest, with numerous epiphytes and woody vines. Many of the larger trees have extensive buttress roots, such as the numerous species of *Dipterocarpus*. In areas of defective drainage the rain forest is replaced by swamp forest, and along the coasts and in tidal estuaries mangroves and nipa palms abound. Another common tree of the coastal and riverine swampy tracts where the water is not brackish is the food-supplying sago palm, which covers extensive areas along the Fly, Sepik and Ramu rivers. Above 3,000 ft. the rain forest in some valleys is replaced by a more mixed forest containing various species of the coniferous genera *Podocarpus* and *Araucaria*. Several of the highland valleys are not forested, but carry a grassland vegetation which is probably as much man-made as a product of nature; cutting and clearing of the forest and subsequent burning of the debris greatly encourage the spread of the tough and pernicious spear grass, or kunai. As cutting and burning are widely practised by the indigenous peoples in their system of shifting cultivation, the rain forest has been considerably modified in many areas. In certain areas on the southern margin of the island, where the rainfall is markedly seasonal, grasslands with occasional trees also occur; an extensive tract of such savannalike vegetation extends from the middle Fly toward the western New Guinea border. At about 6,000 ft. the rain forest is replaced by temperate rain forest, in which the trees are thickly encrusted with lichens and festooned with streamers of moss; the forest floor consists of a layer of moss and decayed vegetation many feet thick. At about 11,000 ft. a specialized alpine forest with stunted conifers, tree ferns and shrubs replaces the temperate rain forest, the limit of tree growth being at about 12,000 ft.

Animal Life.—The fauna of New Guinea shows strong Australian affinities, particularly among the mammals; of more than 100 species, all are marsupials except the echidna or spiny anteater (a primitive egg-laying mammal also found in Australia) and the bats and introduced rodents. The New Guinea environment, however, has greatly encouraged the development of arboreal forms; the tree kangaroo is the largest indigenous mammal. The birds include many representatives of the principal Australian families, but there are also numerous species from the Malayan region, and many remarkable endemic species. Perhaps the best known are the birds of paradise, whose brilliant and colourful plumage made them much sought after in former times. Their capture and export, however, is now rigorously prohibited. (D. W. F.)

ANTHROPOLOGY

New Guinea is a region of considerable racial and cultural diversity. Before 1939 some research was carried out in wide-

NEW GUINEA AND ADMINISTRATIVELY RELATED AREAS

separated areas along the coasts and the Fly and Sepik rivers, and on some of the adjacent islands: the Bismarck and Louisiade archipelagoes, and the Trobriand and D'Entrecasteaux islands. After 1948, a number of intensive studies were made, especially in the central highlands, where the population exceeds 500,000 and where the cultures differ from those of the Sepik to the north of these highlands and of the Fly and Strickland rivers to the southwest.

Racial Types.—The view that the inhabitants of New Guinea must be closely related to the Negroes of Africa, because of their dark skin and eyes, frizzly hair and long heads, is no longer valid. In general, they have a distinctive serological pattern which excludes affinity with African Negroes, as well as with Indonesians, Polynesians, Mongolians and Caucasians. The eastern extremity of New Guinea may be equated with Melanesia. Ethnic links with Australian aborigines are unlikely. The natives are not predominantly dolichocephalic; medium and short skulls occur and also light skins. Stature is short, about 5 ft. for highlanders and slightly taller for coastal natives. Pygmoid groups (usually called Negrito) occur sporadically; they differ serologically from the majority of the New Guinea people and also from other world groups so far examined. (*See* PAPUAN; NEGRITOS.) The population is probably the result of migrations and mixture, but whence and when they came is unknown.

Cultural Characteristics.—The languages spoken may be divided into two groups: Melanesian and the so-called Papuan or non-Melanesian. Those falling within the first category are found in many of the eastern island clusters, in the Schouten Islands northeast of Wewak, in the Markham valley, and in some villages along the northern coast. Papuan types are many; they differ from Melanesian in vocabulary and grammar, and the number of linguistic stocks is unknown.

Despite the great diversity of cultural patterns in New Guinea, the economic, social and political organization is basically similar throughout the island and has much in common with that in Melanesia to the east. Chieftainship is rare and leadership is often based on age and achievement. Widespread systems of ceremonial exchange occur; initiation ceremonies are elaborate and are, in many areas, associated with ceremonial clubhouses for men.

Except for a few unfavourably situated communities, the economy is one of subsistence horticulture and pig keeping. Sweet potatoes are the staple on the highlands; elsewhere taros, yams and bananas are important. Among the Abelam of the Sepik district very large yams are grown, decorated at harvest, and distributed in competitive exchanges by the men. In general, rights over land are vested in kin groups. The leader usually decides when bush is to be cleared and allocates plots among dependents who may lend sections to other kin, affines and friends. The elementary family is an economic unit, but in situations demanding more labour, such as clearing, fencing, housebuilding and canoe construction, neighbours and kin co-operate. Underlying such assistance is the principle of reciprocity.

Natural resources differ considerably and a good deal of local specialization has developed. Much of the trade is conducted through the institution of the "ceremonial partnership" or "trade friendship" in which two men enter into a compact to exchange necessaries and gifts and extend mutual hospitality and protection. The people of Karkar Island, north of Madang, obtain vegetables from the mainland in return for fish; the Motu near Port Moresby used to journey west to the Gulf of Papua to exchange pots for sago; the Wogeo of the Schouten Islands export their nets and Canarium almonds to the mainland for tobacco, utensils, shells, plumes and cosmetics. The Tubetube (Engineer group) is poor in all resources except clay deposits; the inhabitants trade their pots for what they need, and act as middlemen over a wide area. Shells of different kinds function as stores of wealth and to some extent as exchange media in restricted contexts. Such valuables, along with pigs and food, constitute wealth, but only confer prestige when distributed to others; *e.g.*, at feasts, rites, in marriage payments and ceremonial exchange. A classic example of the last, described by B. K. Malinowski, is the *kula* of the Massim, linking island communities in a circuit of exchange in which red shell necklaces are handed on from partner to partner in a clockwise direction in return for white armlets. Long overseas voyages for this purpose are made and opportunity is taken to trade in food and artifacts, many of which are of very fine workmanship. It is impossible to do justice here to the richness of New Guinea art, particularly in the Gulf of Papua, the Sepik district and the Bismarck archipelago, but notable are the carvings, masks and superbly painted façades of the Abelam clubhouses, the fretted prow-boards of the Trobriands, and the delicately incised lime gourds, spatulas, daggers and shields of the Massim and Sepik. Apart from the production of polished greenstone blades, the highlands are relatively poor in the graphic and plastic arts but are noted for the glowing headdresses of bird-of-paradise plumes worn by the men on ceremonial occasions.

Social Organization.—Villages are usually small with populations ranging from 50 to 300, but larger groupings of 500 to 1,000 occur in the Sepik area. The settlement pattern varies: houses may cluster in a compact group and are sometimes palisaded (eastern highlands), or encircle or line a ceremonial ground (Trobriands and the Iatmul on the Sepik river). In the central and western highlands the homestead pattern prevails. Whatever the distribution of huts, it is common for close kin (usually connected unilineally) to build near one another. Sometimes a hamlet, village or neighbourhood consists only of the male members of a clan or lineage with their wives and children; sometimes it is composed of a number of clans or clan sections, and members of the community are linked by cognatic and affinal ties.

In much of the Bismarck archipelago and Massim area, descent and inheritance are matrilineal, but on the mainland it is much more difficult to generalize. In some communities, such as the Garia of Madang, unilineal descent groups are only weakly developed, and a man maintains relations with a wide range of kin. Nonunilineal or ambilineal descent, in which membership can be claimed in the descent groups of either parent, has been reported in what was formerly Netherlands New Guinea and among the Huli (central highlands). On the whole, most of the kinship systems so far studied show a bias toward a patrilineal reckoning of descent, but there is considerable flexibility in affiliation; genealogies are of shallow generation depth, and great importance is attached to affinal and uterine relationships.

The village is an autonomous political unit. Intercommunity relations are for the most part characterized by hostility and fighting, with intermittent periods of truce; alliances with neighbours are often temporary. Distinctions of rank occur in only a few areas (northern Massim and Manam Island); elsewhere societies are egalitarian, and status is determined by kinship, age and achievement. With few exceptions authority is vested in the elders of small localized clans or subclans and they act as an informal council in matters affecting the community as a whole. Among these, certain individuals achieve a dominant role as leaders on the basis of prowess in warfare, oratory and especially the ability to accumulate, manipulate and distribute wealth. They act as entrepreneurs in economic activities and rituals, and are able to exercise some influence in the settlement of disputes.

Ritual and Belief.—These vary, but there is widespread belief in spirits. They are frequently associated with parts of the bush or rivers; they may assume the guise of animals; and, along with ancestors, may be impersonated in initiation ceremonies. Fully developed ancestor cults do not obtain, except perhaps in Manus (in the Admiralty group), but a belief in spirits of the dead appears to be universal. Sacrifices are sometimes made to them in connection with warfare, gardening and hunting; and mortuary ceremonies are often complex, involving the distribution of food and valuables. Fertility cults associated with sacred flutes occur on the highlands; and nearly everywhere elaborate initiation rites for men take place. Complex systems of productive magic for economic and other activities are typical, and belief in sorcery and black magic is also widespread. Indeed, accusations of sorcery are among the most frequent causes of intervillage hostilities.

Cultural phenomena of New Guinea and of much of Melanesia are the so-called cargo cults (*q.v.*), of which the Vailala Madness (rebellion) of the Purari delta and the Taro cult of the Orokaiva

people near Buna were early examples. During and after World War II many forms of these cults appeared; in general, they postulate the disappearance of the Europeans and the acquisition of their cargo (wealth) by the natives. (P. M. K.)

HISTORY

Early European Contacts.—For 400 years the history of New Guinea is of discovery, exploration and tentative annexation, as one European nation after another led the world in navigation and commerce. A Portuguese, Antonio d'Abreu, sighted the coast in 1512, but discovery is usually attributed to the Spaniard, Jorge de Menezes, who landed on the north coast in 1527. Inigo Ortiz de Retes gave New Guinea its name in 1545, and claimed it for Spain. The subsequent supremacy of Dutch sea power brought William Jansz (1605–06), Luis Vaez de Torres (1606), Jacques le Maire and Willem Schouten (1616) and Abel Tasman (1642). The Dutch East India company claimed a large, undefined part of the mainland for the Netherlands in 1660, but failed to establish a profitable trade.

William Dampier (1699–1700) and Philip Carteret (1767) were the first Englishmen to navigate these waters, and charted the islands now known as New Britain, New Ireland and Buka. Later English visitors were James Cook (1770), T. Forrester (1774), Lieut. T. G. Shortland (1788–89), J. Hunter and J. McCluer (1791). New Guinea came within the monopoly area of the English East India company, which for some years after 1793 maintained a garrison at Restoration bay. A claim of annexation was made, but nothing came of it. L. A. de Bougainville initiated a series of French expeditions in 1768. In 1828 the Dutch government erected Fort de Bus, and declared northwest New Guinea part of the empire. Twenty years later, the frontier was stated to run from Cape Bonpland to the north coast.

From the 1840s European interest in the rest of the island steadily increased. The most notable explorers of this period were F. P. Blackwood (1842–46), Owen Stanley (1846–50), Charles Yule (1846) and J. Moresby (1873). Both Yule and Moresby claimed the southern coast for the British empire, but the imperial government repudiated their actions. The first German investigators were Gustav Schleinitz and Otto Finsch. E. Teysmann, P. van der Crab and others led expeditions on behalf of the Dutch East Indies government. A pioneer scientific survey was made by A. R. Wallace in 1858, and in the same year the Utrecht Mission society settled at Port Dorey. Twelve years later the London Missionary society sent Samuel MacFarlane and A. W. Murray from the Loyalty Islands to Darnley Island in Torres strait. A station opened at Port Moresby in 1874 became the centre of mission activity on the mainland, to which came during the 1870s W. G. Lawes and James Chalmers (*q.v.*), two outstanding personalities.

By this time, expressions of the European interest in the riches of New Guinea had become more definite. From the 1840s miscellaneous traders, often unscrupulous and belligerent, took trepang, cedar, ebony, sandalwood, rubber, pearls and copra. Two abortive enterprises, the New Guinea company (1867) and the New Guinea Prospecting association (1871), were formed in Sydney; wild stories of gold discoveries caused a rush to the Mai-Kusa river in 1877. As so often happened in the history of New Guinea, the resources of the island had been exaggerated far beyond reality.

From 1857, when the Hamburg firm of J. C. Godeffroy was established in Samoa, German commercial power in the South Pacific had steadily grown. In 1880 the Deutsche Seehandelgeschaft was formed in Berlin to exploit New Guinea resources. This expression of German interest considerably strengthened opinion in Australia that Great Britain should annex eastern New Guinea. There was, too, fear of French expansion, and growing hope among Australian capitalists that the island promised riches. The consequent feeling reached a climax in March–April 1883 when Sir Thomas McIlwraith, premier of Queensland, caused eastern New Guinea to be annexed in the name of Great Britain. The British cabinet again determined to disallow annexation. However, in 1884 Bismarck announced that he would protect German traders in the Pacific, where they possessed commercial preponderance. This step moved the British government to authorize the declaration of a temporary protectorate over an undefined area of southeastern New Guinea (Nov. 6, 1884). Ten days later the German flag was raised on the northeast coast.

West New Guinea.—The adjustments of 1884–85 established the meridian 141° E. as the division between West (Netherlands) New Guinea and the areas annexed by both Germany and Great Britain, a division slightly altered in 1895 by the substitution of the Fly river as part of the boundary with the British territory.

The basis of the original Dutch claim to New Guinea had been the nominal suzerainty of the sultan of Tidore, a Dutch dependency, over a vague area of the western part of the island. Southwest New Guinea was officially purchased from the sultan by the Netherlands in 1905. West New Guinea was attached to the Amboina residency in 1911, and after many years' negotiation, the northwest division was legally transferred to the Netherlands when Indonesia became independent in 1949. During World War II the Japanese conquered all but the extreme southeast coast line. Gen. Douglas MacArthur's headquarters were established at Hollandia (Kota Baru) for a time.

Following the establishment of Indonesia, the new republic asserted that West New Guinea (Irian Barat; West Irian) should be released by the Dutch. Indonesia pressed its claim with great vigour throughout the 1950s; the issue became important in the republic's domestic politics and exacerbated its relations with the Netherlands and Australia. Matters came to a head early in 1962, when Indonesia threatened to invade West New Guinea unless its administration was quickly handed over by the Dutch. A number of armed clashes followed between Dutch and Indonesian forces, but by the end of July the two countries had negotiated an agreement (signed at UN headquarters Aug. 15, 1962) under which the Dutch handed over the administration of West New Guinea to the UN on Oct. 1, while provision was made for the administration to be transferred to Indonesia on May 1, 1963, and for a plebiscite to be held by 1969 to decide the area's future. Accordingly, Indonesia took over the administration on May 1, 1963.

UN Trust Territory.—The area annexed by Bismarck in 1884 comprised the Bismarck archipelago (New Britain, New Ireland and the Admiralty islands), the northern Solomon islands and the mainland between 2° 15′ S. and 8° S. and 141° to 148° E. The mainland division was known as Kaiser Wilhelmsland. In May 1885 the Neu-Guinea Kompanie was given an imperial charter of protection over the entire area. Rights of sovereignty and administration were vested in the company, although any laws had to be made by the German parliament. The company's early years were unsuccessful. The science of tropical agriculture was then insufficiently developed; native labour was inefficient; the importation of Chinese coolies became unworkable; disease killed natives, Europeans and cattle. At the company's request, its administrative functions were taken over by the German government between 1889 and 1893. The seat of government was removed from Finsch Harbour to Stephanscourt, then to Friedrich-Wilhelms Harbour (Madang), and finally to Herbertshöhe (Kokopo). The German government ultimately assumed full control in 1899 when Rudolf von Benningsen was appointed governor. The following years were marked by greater stability in the plantation economy. The chief crop was copra, which was harvested extensively along the coast and on the islands. Notable progress was made in various scientific inquiries such as botanical research, tropical medicine and anthropology.

Following the declaration of war in Aug. 1914 Australian troops landed on the eastern shores of the Gazelle peninsula. Within a week the Germans capitulated and until 1921 the *status quo* was maintained by the Australian military administration. Former German New Guinea was then assigned to Australia as a mandate under the League of Nations. The New Guinea act, 1920 (proclaimed May 1921), established a civil administration and introduced a new set of ordinances. These aimed at achieving justice before the law; preservation of rights of cultivation, barter, fishing and hunting; and protection of tribal institutions. The supply of opium, intoxicating liquor, ammunition and firearms to the natives was forbidden.

When Australia took over, only a small part of the territory

was under even partial control, but gradually district officers, patrol officers and the indispensable native constabulary pushed farther into the interior. An area would be put first under "partial influence," then "influence" and finally "control." Penetration was accelerated by the gold rushes to Edie Creek in 1925, and later to the headwaters of the Purari and Ramu rivers. Roman Catholic, Lutheran and Seventh-day Adventist missions were established south of the Bismarck ranges by the mid-1930s.

One problem facing the administration was the development of a trained civil service. Constant reorganization was necessary, and although a cadet system was instituted in 1926, the pressure of the gold rushes forced its suspension soon after, and it was not resumed until 1939. Copra remained the basis of the economy, but by 1938 experiments had also been made with kapok, tobacco, wood pulp and coir fibre; these were all grown on the islands rather than on the mainland. The administration aimed at strict and just control of the native indenture system, and attempted, during the later 1930s, to enforce a provision requiring the labourer's consent. Nevertheless, there was some criticism of this feature of the administration before the Mandates commission. Education lay chiefly in the hands of the missions. Central hospitals and medical patrols were established to protect native health.

In 1942 the territory was invaded and partially occupied by the Japanese. By April the civil administration was suspended in both Papua and the mandated territory and replaced by the Australian New Guinea Administrative unit. Following the Japanese surrender, civil administration was progressively restored between Oct. 1945 and June 1946, and since then the two sections have formed one administrative unit. On Dec. 13, 1946, the UN general assembly approved the agreement by which the trust (*i.e.*, former mandated) territory remained under Australian supervision.

Papua.—The administrative system established immediately after the declaration of a British protectorate over the southeast of the island (1884) provided that the Australian colonies should take political and financial responsibility, while Great Britain undertook to provide a special commissioner to lead the local government. This arrangement having proved unsatisfactory, it was altered by the British New Guinea (Queensland) act of 1887. Queensland (with the financial assistance of New South Wales and Victoria) was to supervise the administration and report back to the imperial parliament; after ten years this "joint control" was to cease through Great Britain's withdrawal, the area was to be at once formally annexed and a lieutenant governor appointed.

From 1887 to 1897 Papua was administered by Sir William MacGregor. With the assistance of a legislative and an executive council, both nominated by himself, he created a framework of government of which a notable feature was the role played by natives, both in the constabulary and as village police. Moreover, in administering justice an attempt was made to allow for native concepts. MacGregor determinedly tackled the essential features of colonial policy—native agriculture, land regulation, the protection of native labour and the preservation of the village unit. Although he has been accused of arrogance, his achievement appears, under the circumstances, to have been worthy of note.

From 1898 to 1903, during Sir George le Hunte's lieutenant governorship, control passed to the Commonwealth of Australia. The chief policy development was the improvement in health services. However, after the status and title of Papua were defined in the Papua act, 1905, a more lively interest appeared in Australia. This was expressed by the appointment of the 1906 royal commission, which emphasized the desirability of European investment and settlement. Liberal terms for long leasehold were offered to prospective settlers in a lands ordinance of the same year.

The next lieutenant governor (which office he combined with that of chief justice) was J. H. P. (Sir Hubert) Murray. As he held office for more than 30 years (1907–40) the extent to which his personality and abilities constitute the history of Papua was considerable. In pursuit of native welfare his basic policies were broadly the same as MacGregor's: for example, the Natives Plantation ordinance fostered indigenous agriculture and revenue—with some success, for in the following years not only copra but coffee, rice and rubber were grown by Papuans. The policy of indirect rule was kept to the forefront, and partially realized by the successful introduction of village councils. Financial stringency restricted provision of health and, even more, educational facilities.

Murray, however, was concerned not only with native welfare but also with economic development. During his term of office the number of acres under cultivation rose from 1,467 to 63,609. But these figures give a rather false impression, for economic progress never came as fast or as easily as Murray hoped and many people expected. The Australian market was insufficient to absorb the production of copra and rubber, hence there was a great need for cheap freighting of these products so they could compete in the world market. However, from 1921 to 1925 freight charges were forced up by the Navigation act, which required that all exports be shipped through Sydney, and limited competition among the shipping lines. Papua was barely recovering from the effects of the act, when the world depression of the 1930s dealt further severe blows. Gold and, to a lesser extent, copper added to the value of exports. But it was oil which aroused Murray's highest hopes: hopes which remained unrealized in the early 1960s despite tremendous sums spent in investigation.

The post-World War II years saw a quickening of official concern with Papua. In July 1945 the minister for territories, E. J. Ward, announced his intention to establish a new labour policy which would aim at the abolition of the indenture system—an ideal of Sir Hubert Murray. A new post of administrator of the combined territories was created, the office being held first by J. K. Murray and then (1952) by D. M. Cleland. The foundation of the School of Pacific Administration (1946) and the South Pacific commission (1947) represented further moves toward an efficient and informed administration. P. M. C. Hasluck, minister for territories from 1951, reversed earlier hints that R. G. Menzies' Liberal governments (1949–) might be partial to European, as against native, welfare. Nevertheless there developed various elements—a strong settler interest, native awareness of politics, an administration well-meaning but irredeemably paternalist—which threatened to join with economic instability to produce a difficult colonial situation. In Australia criticism of the administration and suggestions for any change in the island's political status were generally regarded with suspicion. (O. M. R.)

POPULATION

Despite the large size of the island, the population of New Guinea is scanty, a reflection of the extreme difficulties presented by the environment; the way of life of many New Guinea peoples makes dense populations impossible. The total population (1961 est.) of New Guinea, including that of several small island groups

Administrative divisions	Area (sq. mi.)	Population (1961 est.)		Administrative centre
		Indigenous	Nonindigenous	
New Guinea Trust Territory*	92,160	1,433,383	15,536	Port Moresby
Papua Territory	86,100	513,648	9,794	
West New Guinea	160,618	700,000	36,731	Sukarnapura (Hollandia)

*Includes area (23,273 sq. mi.) and population (233,239) of the Bismarck Archipelago and Buka and Bougainville Islands of the Solomon Islands), which constitute a part of the New Guinea Trust Territory.

within the former Dutch and the Australian-administered areas, was 2,709,092; this includes estimates of about 300,000 for areas of West New Guinea, and of almost 250,000 for areas in the Australian territories, not yet brought under firm administration. The total European population numbered about 36,000, of whom nearly half were in West New Guinea; total nonindigenous population was 62,061. The European proportion, however, was inflated by the inclusion of a large number of Eurasian immigrants from Indonesia in the Dutch statistics, in conformity with the practice of the former Netherlands Indies which recognized such peoples as Europeans. The remaining nonindigenous people are mainly Asians. In the Australian territories the Chinese are the most important elements in this group; they are mainly urban

shopkeepers and traders, and are most numerous in the trust territory, which is economically the most advanced part of the island. There are very few Chinese in West New Guinea and the Asian population consists largely of Ambonese and other Christian peoples from Molucca province, Indon., who were unwilling to remain in Indonesia when sovereignty was transferred in 1949.

The distribution of the indigenous population is very uneven, and large parts of the island are virtually uninhabited. The densest populations are found on the areas of better soil, particularly where derived from recent volcanic activity. Thus the island of New Britain in the New Guinea trust territory, and certain other small volcanic islands off the northern coast, have populations of above average density; certain of the valleys of the eastern highlands district are relatively densely populated, parts of the Chimbu area having a density of almost 300 persons per square mile. Such high densities are, however, quite exceptional. In West New Guinea the highest densities are found in the islands of Geelvink bay (Biak, Noemfoor and Japen) and in certain valleys of the central highlands.

The nonindigenous population is almost entirely urban, but all the towns are of small size; Rabaul in New Britain (New Guinea trust territory) has a population of (1958 est.) 8,400. Port Moresby (on the south coast of the tail of New Guinea), the administrative centre of the Australian territories, has a municipal population of (1961 est.) 22,243; the largest town in West New Guinea is the administrative capital of Sukarnapura (formerly Kota Baru) on the north coast, with about 14,100; Sorong (on the west coast of the island's "head"), the headquarters of the petroleum industry in West New Guinea, has 9,150.

ADMINISTRATION AND SOCIAL CONDITIONS

The trust territory of New Guinea and the territory of Papua form an administrative union under the control of the department of territories in Canberra. There is an administrator who is assisted by an administrative council which, until 1964, consisted of the administrator and six members of the legislative council (three of these being territorial officers and three being other members, of whom at least two had to be elected council members). Until 1964 a legislative council was empowered to make ordinances but these had no force until assented to by the administrator or the governor general, and its function was mainly advisory. After 1961 the legislative council had an unofficial majority; it was made up of the administrator as president, 14 official members drawn from heads of departments, 6 elected and 5 nominated indigenous members and 6 elected and 5 nominated nonindigenous members. Each of the nine administrative divisions of New Guinea territory and the six divisions of Papua territory provided an observer.

In 1962 a mission of the United Nations Trusteeship council visited the territories and urged an acceleration of progress toward self-government. As a result of the mission's report the territories established their own select committee on political development and recommended the creation of a parliament with an indigenous majority. In 1963 the Australian parliament passed a law providing for the establishment in 1964 of a house of assembly, composed of 10 official members, 44 members elected from a common roll and 10 nonindigenous elected members.

The administration of Netherlands New Guinea was exercised by a governor appointed by the crown and assisted by a council of heads of departments. There was a legislative council composed of 13 elected and 10 nominated indigenous members, and 5 Europeans. A number of local advisory councils were also set up, in which the indigenous peoples participated. There were six administrative divisions in Netherlands New Guinea. There were liaison officers at Port Moresby and Kota Baru (formerly Hollandia), respectively, to facilitate co-operation between the Dutch and the Australian administrations, and in the 1950s such co-operation increased.

By the 1962 agreement West New Guinea was administered by the United Nations Temporary Executive authority (UNTEA). This consisted of an administrator appointed by the secretary-general of the UN, assisted by departmental heads who were to be neither Dutch nor Indonesian. As many indigenous persons as possible were to be included in the administration, and others might be recruited from Indonesia. The administration was turned over to Indonesia in May 1963.

Taxation.—An income tax was levied in the Australian territories for the first time in 1959, import and export duties having previously accounted for the greater part of the locally derived revenue. Adult males in the Australian territories pay a personal tax, except where they are liable for an equivalent or higher tax levied by native local government councils. In Netherlands New Guinea income tax was levied on both indigenous and nonindigenous inhabitants.

Living Conditions.—The great majority of the indigenous population is engaged in subsistence farming and is organized in village communities which have a high degree of self-sufficiency. The employment of native labour is controlled by both administrations in order to prevent the disruption of native society, and to check the social problems that would arise from an over-rapid expansion of the urban areas, in which most of the opportunities for western-type employment are to be found. The total number of workers in paid employment in the late 1950s was only about 80,000, of whom more than half were employed in the trust territory of New Guinea; about 21,000 were employed in the territory of Papua and about 16,000 in Netherlands New Guinea. In the Australian territories the employment of indigenous workers is limited to two years, with the possibility of an extension for a further year except in the case of natives from the highlands recruited to work in the coastal lowlands. The European coconut and rubber estates account for almost half the total native employment in the Australian territories, but in Netherlands New Guinea most native workers were employed in building and construction, and in domestic service.

Minimum rates of pay for most classes of native workers are determined by ordinances in all territories; minimum standards of housing are also specified where this is provided by employers, as is usually the case. There are no real trade unions but there are workers' associations in the Australian territories, whose development is being encouraged by the administration.

Welfare Services.—The principal welfare services are provided by the respective departments of health and by the missions. In the Australian territories simple medical treatment is provided free in village dispensaries, and medical patrols penetrate into the outlying areas. Most of the larger centres have hospitals for indigenes operated by the administration, which also assists those operated by the missions through grants-in-aid and the provision of supplies. Broadly similar arrangements existed in the Netherlands territory.

Justice.—In the territories of Papua and New Guinea, courts for native matters deal with civil actions in which all the parties are indigenes, and with breaches of the native regulations; courts of petty sessions try summary and nonindictable offenses. The highest judicial authority is the supreme court of the territories of Papua and New Guinea. Internal order is maintained by the Royal Papua and New Guinea constabulary, whose native members are recruited by voluntary enlistment. Judicial organization in Netherlands New Guinea had much in common with that of the former Netherlands Indies, justice in certain areas being administered in conformity with native customary law.

Education.—The provision of educational facilities for a sparse and scattered population, much of which has limited contact with European activity, has presented many problems. Both administrations provide different facilities in the urban areas—where there has been the greatest contact with European activities—from those in the rural areas. Village schools tend to stress basic manual and technical skills, but in the Australian territories literacy in English is also a major educational aim. In the towns the facilities for elementary education are broadly similar to those of the Netherlands and Australia, respectively, but intermediate and secondary education is still on a rather limited scale. In West New Guinea education has been largely in the hands of the missions, whose activities were subsidized. In the Australian territories government schools are relatively more impor-

tent, although the missions still serve the largest number of pupils.

THE ECONOMY

The economic development of New Guinea has been greatly hindered by physical obstacles, a very limited labour supply of low productivity and, before World War II, the preoccupation of the two administrations with other interests. For the Netherlands, New Guinea was never more than a distant and thinly populated marginal territory of the populous Netherlands Indies, and Australia's main concern was with strategic considerations. It was only after 1945 that the two administrations allocated enough funds to make a modest rate of economic development possible. It was clear that for some time to come the main stimulus to economic development must be provided by nonindigenous peoples, but both governments were endeavouring to promote a higher level of indigenous economic activity, consistent with their policies of easing the transition from a multiplicity of self-sufficient village economies to a commercialized, territorial economy. The greater part of the native land is held in communal tenure; no land can be acquired from native owners except by the administration.

Agriculture.—Subsistence agriculture is predominant in the economic life of New Guinea, the traditional food crops including sweet potatoes, taros, yams and bananas, grown on small garden plots under a system of shifting cultivation, or bush fallow. Near towns, and where transport facilities are available, surplus foodstuffs may be offered for sale, and some cash crops are usually cultivated. In certain restricted parts of the island, generally on the coastal areas of better soil, European estate agriculture is found, and there the cultivation of similar crops has also been taken up by native smallholders, with governmental support. The greatest development of commercial agriculture largely directed to an export market is in the trust territory, where the growth of estate agriculture owes much to the former German administration. Coconuts are the most important crop; there are about 350 estates totaling 350,000 ac., approximately half of which are in New Britain and New Ireland; the greatest concentration is in the Gazelle peninsula. In the years after World War II there was marked increase in planting by native growers. A leading activity in the Gazelle peninsula is the cultivation of cacao by native growers organized into co-operatives, and by the early 1960s about 10,000 ac. had been planted. Cacao is also grown by small holders in other parts of New Guinea territory, and there is a small production of coffee and tea in the highlands. Labour shortages operate against the extension of estate agriculture, and the provision of labour for existing estates presents many problems. In Papua territory coconut estates are less numerous than in New Guinea territory, but about 30,000 ac. are under rubber. Ten estates in the vicinity of Kanosia and Sogeri, within easy reach of Port Moresby, produce about two-thirds of the annual output of about 4,000 tons. Commercial agriculture in West New Guinea is on a much more limited scale; the total area under coconuts is estimated at about 25,000 ac.

The only livestock kept by the indigenous population of New Guinea consists of pigs and poultry; cattle are few in number and are kept entirely by Europeans. Fishing is universal around the coasts, but commercial fishing is confined to the vicinities of the major settlements.

Mining.—The principal mineral product is petroleum, which is produced by a mixed British, Dutch and U.S. company in the Klamono, Wasian and Mogoi areas of the Vogelkop peninsula in West New Guinea. Petroleum was discovered shortly before World War II, but the search for further oilfields was disappointing. At the end of the 1950s production was about 500,000 tons a year but by the early 1960s it had declined to around 150,000 tons; crude oil is shipped from Sorong for refining in Australia. Considerable effort has been expended on the search for oil in the Australian territories, principally at the head of the Gulf of Papua. The main mineral product of the Australian territories is gold, which is largely produced from alluvial deposits in the Wau-Bulolo area in the trust territory of New Guinea, though a little is also produced from the Kieta area of Bougainville Island. Annual production of gold declined from almost 300,000 oz. in 1940 to less than 50,000 oz., and only one of the former eight dredges was still working in the early 1960s.

Manufacturing Industries.—Because of limited markets, lack of power and poor transport facilities, industrial development is on a very small scale and is largely confined to the processing of local raw materials. The main activities are copra drying and crushing, cacao fermentation and sawmilling; there is also a plywood factory in the Bulolo valley, one of the main centres of timber production. Small food and drink plants are found at Lae, Rabaul and Port Moresby and in some of the larger centres in West New Guinea. Manokwari on the Vogelkop peninsula has a sawmill, a shipyard and a small oxygen plant, and there are a number of industrial activities at Sorong in connection with petroleum production.

Trade and Finance.—The bulk of the trading activities has been in the hands of Europeans, and to a lesser extent of Asians. External trade is small and in both Australian and western territories there is an excess of imports over exports, indicative of the low level of economic development in the island. However, the adverse trade balance is comparatively slight for the trust territory of New Guinea, which generates by far the larger proportion of the exports of the Australian-administered portion of the island. The principal items in the export trade are copra and coconut oil, rubber, cocoa beans, gold and plywood. The trade of Papua territory is almost entirely with Australia, but the trust territory is heavily dependent upon the United Kingdom as a buyer for its exports. Crude petroleum, copra and nutmeg are the principal exports of West New Guinea. Both the Netherlands and Australian governments paid a large subsidy to maintain the administration of their respective territories.

Communications.—Transport facilities are poor or nonexistent over much of New Guinea, and the lack of such facilities is probably the biggest obstacle to economic development. There are no railways, and roads are confined to the immediate vicinity of the towns. After World War II there was a growing awareness of the desirability of a better road system, and there was a considerable extension of roads suitable for cross-country vehicles such as jeeps in the Australian territories. To some extent the shortcomings of land transport are made good by a remarkable development of air transport, but its commercial impact is slight. Most estates are dependent upon coastal shipping for their supplies and for transporting their produce. Commercial activity is thus largely confined to the immediate vicinity of the coasts. The principal ports are Rabaul, Lae, Madang, Kavieng (in New Ireland), Port Moresby, Salamaua and Samarai in the Australian territories, and Kota Baru, Sorong, and Merauke in West New Guinea.

There are about 6,000 telephones in the Australian territories. The Australian Broadcasting commission operates a station at Port Moresby. External communications are by means of radio telegraphy; an administrative radio telephone channel connects Port Moresby and Kota Baru. *See* also references under "New Guinea" in the Index. (D. W. NEWHAM, one of the 32 London boroughs constituting Greater London, Eng., lies about 4 mi. (6 km.) E of the City. The Thames forms its southern boundary while to the west and east the Rivers Lea (Lee) and Roding broadly separate it from the neighbouring boroughs of Tower Hamlets and Barking; it has a short boundary with Hackney in the northwest and is bounded in the north by Waltham Forest and Redbridge. This outer London borough was established on April 1, 1965, under the London Government Act 1963 (*see* LONDON) by the amalgamation of the former county boroughs of East Ham and West Ham and small parts of Woolwich (north of the Thames) and Barking. Area 14.5 sq.mi. (37.6 sq.km.). Pop. (mid-1965 est.) 260,070. It comprises four parliamentary constituencies and includes the districts of North Woolwich, Silvertown, Custom House, Canning Town, Plaistow, Upton Park, East Ham, Manor Park, Little Ilford, Forest Gate, and Stratford.

Newham's northern and eastern parts are mainly residential. To the south the extensive Royal Docks predominates in a large Thames-side industrial area which concentrates on ship repairing, engineering, milling, gas, and manufacturing industries. In the northwest chemical and allied trades prevail and there are railway yards at Stratford.

Two major routes eastward from the City traverse the borough —Barking Road (an extension of the Commercial and East India Dock roads) and Romford Road (an extension of the Whitechapel, Mile End, Bow roads, and High Street), and, in the south, the Silvertown Way and the East Ham-Barking By-Pass connect with the Royal and Tilbury docks. The North Circular Road which enters Newham via Wanstead ends at North Woolwich where the free ferry conveys vehicular and passenger traffic across the Thames. Newham is served by the District and Central lines of the London Underground, and the Eastern Region of British Rail provides links with Tilbury, Southend, and East Anglia.

Newham was previously in the county of Essex (*q.v.*), and Wanstead Flats, on its northern boundary, is a detached portion of Epping Forest. In all there are about 400 ac. (162 ha.) of parks and open spaces including West Ham Park (77 ac. [31 ha.]) which is maintained by the Corporation of London.

The Abbey of Stratford Langthorne was founded in 1135 by William de Monfichet, Lord of Ham (Hame in the Domesday Book); this Cistercian house, which flourished for four centuries, was responsible for draining the riverside marshes and for developing agriculture and a substantial wool trade. The churches of St. Mary Magdalene (East Ham), St. Mary (Little Ilford), and All Saints (West Ham) date from the Norman period.

Few other buildings in Newham are more than a century old as the growth of the area was the result of the 19th-century industrial expansion of London. In the southwestern section especially, rapid and unplanned extension resulted in poor social and housing conditions. By the 1960s much of the substandard housing, which sustained widespread damage and destruction during World War II air raids, had been replaced by blocks of flats and modern estates, while new roads, schools, and clinics contributed to the changing face of the borough.

The West Ham College of Technology, opened in 1898, the largest of the educational establishments, is a regional college affiliated with the University of London, and the adjacent Passmore Edwards Museum contains items of natural and local history, and a collection of locally made Bow China. Lord Lister (1827–1912), who introduced antiseptic surgery, was born at Upton House, and the Jesuit poet Gerard Manley Hopkins (1844–89) was born at Stratford. Elizabeth Fry, the philanthropist, lived successively from 1809 till her death in 1845 at Plashet and Upton Lane House (both premises now demolished). (J. H. F. K.; Fx. S.)

NEW HAMPSHIRE, popularly known as the "Granite state," is one of the New England group of the United States and one of the original 13, being the ninth to ratify the constitution. It is bounded north by the Canadian province of Quebec; east by Maine, and by the Atlantic ocean; southeast and south by Massachusetts; west and northwest by Vermont (from which it is separated by the Connecticut river—the low-water mark on the west bank of the Connecticut is New Hampshire's west boundary) and by Halls stream, which separates it from Quebec. The state has an area of 9,304 sq.mi., of which 290 sq.mi. are water surface; it is the 44th state in size. The state flag of New Hampshire is a field of blue on which is a representation of the state seal surrounded by a wreath of laurel leaves with nine stars interspersed. The state flower is the purple lilac (*Syringa vulgaris*), the state bird (unofficial) the purple finch. The capital of New Hampshire is at Concord (*q.v.*).

PHYSICAL GEOGRAPHY

Physical Features.—In the north-central portion of the state which lies between approximately 42° 40′ and 45° 18′ N., and between 70° 37′ and 72° 37′ W., the White mountains (*q.v.*), a continuation of the Appalachian system, rise abruptly in several short ranges and in outlying mountain masses from a base level of 700 to 1,500 ft. The highest peak, Mt. Washington (*q.v.*), attains an elevation of 6,288 ft. The principal ranges, the Presidential, the Franconia and the Carter-Moriah, have a northeastern and southwestern trend. The Presidential, in the northeastern part of the region, is separated from the Franconia on the southwest by the Crawford or White mountain notch, about 2,000 ft. in depth, in which the Ammonoosuc and Saco rivers find a passage, and from the Carter-Moriah, parallel to it on the east, by the Glen-Ellis and Peabody rivers, the former noted for its beautiful falls. On the Presidential range, which is about 20 mi. in length, are Mt. Washington and nine other peaks exceeding 5,000 ft. in height. On the Franconia, a much shorter range, are Mt. Lafayette, 5,249 ft.; Mt. Lincoln, 5,108 ft.; and four others exceeding 4,000 ft. The highest peak on the Carter-Moriah range is Carter Dome, 4,843 ft.; but seven others exceed 4,000 ft. Separating Franconia and Pemigewasset ranges is the Franconia notch, overlooking which from the upper cliffs of Profile mountain is the Great Stone Face, immortalized by Nathaniel Hawthorne.

The part of the state that lies north of the White mountains is occupied by ridges and wide rolling valleys, the ridges rising occasionally to heights of 2,000 ft. or more. South of the mountains a plateaulike surface—a part of the New England uplands—extends from the intervales of the Connecticut river to the eastern border of the Merrimack valley. Between the Merrimack valley and the sea is the only low surface in the state; a considerable portion of this region is less than 500 ft. above sea level. The seashore, about 18 mi. in length, is mainly a low sandy beach. The only harbour is at Portsmouth near the mouth of the Piscataqua. About nine miles from the shore are the bleak and nearly barren Isles of Shoals, divided between New Hampshire and Maine.

The lakes and ponds, numbering several hundred, were formed by glacial action; and the scenery of many of them is scarcely less attractive than that of the mountains. The largest and most widely known is Lake Winnipesaukee, 20 mi. long and 12 mi. wide, dotted by 274 islands, mostly verdant. The rivers with their

numerous falls and the lakes with their high altitudes furnish a vast amount of water power for manufacturing—the Merrimack, in particular, into which many of the larger lakes, including Winnipesaukee, find an outlet.

Climate.—The winters are usually long and severe, and the summers cool and fine. The mean annual temperature ranges from about 40° F. (about 4.4° C.) at only moderate elevations in the White mountain region and farther north to 47° F. (about 8.3° C.) at low altitudes in the southeast. The greatest extremes of temperature occur in the deep mountain valleys, where it sometimes rises to 102° F. or above in summer and falls to −38° F. or below in winter; higher up on the mountains it is never so warm, and along the seacoast both extremes are considerably less. The mean precipitation for the entire state is about 40 in. The distribution is even throughout the year, but summer and autumn are slightly wetter than winter and spring. Among the mountains and in the northern part of the state the annual fall of snow is from 7 to 8 ft., but in the southeast corner it is little more than one-half that amount. The prevailing winds are generally northwest, but in the vicinity of the sea they are southeast during summer.

Soil.—Fertile soil in New Hampshire is confined largely to the bottomlands of the Merrimack and Connecticut rivers. In the southeastern section is also a moderately productive soil derived largely from the disintegration of slate. Elsewhere south of the mountains, the surface soil is mostly hardpan or till, this being deepest on the drumlins. In the mountain region the soil is mostly a sandy loam composed of disintegrated granite gneiss and organic matter.

Vegetation.—Flowering shrubs and vines are found in abandoned fields and pastures and beside the roads, chiefly wild grapes, pin cherry and chokecherry, sweet fern, red osier, American elder, several varieties of sumacs, sheep laurel or lambkill, elderberries, blackberries, blueberries, both lowbush and highbush, and raspberries. Mountain laurel is commonest in the Monadnock area, while the flowering dogwood is confined chiefly to the lower Connecticut valley region. The wild flowers of the state include goldenrod, asters, fireweed, paintbrush, daisies, black-eyed Susans, painted and purple trilliums, fringed gentian, blue, yellow and white violets, trailing arbutus, lady's-slippers, Indian pipe, several varieties of honeysuckle, lilies, blue flag iris, ferns and bracken. On the higher elevations are found alpine plants, such as Labrador tea, mountain sandwort, cinquefoil, as well as arctic rushes, sedges and lichens.

Animal Life.—Deer and bear are the most abundant of the larger animals, and there are a few moose. Mink, beaver, raccoon, pine marten, otter, Canadian lynx and fisher inhabit the state, although the last two are decreasing in number. Red and gray squirrels, striped chipmunks, skunks, porcupines, moles, shrews, wood and meadow mice, the fox and the cottontail are common, while snowshoe rabbits are found in the northern part.

Historic Sites, Parks and Recreation.—New Hampshire has many places of historical interest. Among them are the Woodman institute in Dover, which includes the Dam Garrison, built in 1675, and the Gilman-Clifford, or Garrison, house (1650–58) in Exeter, of which a part is claimed to be at least the second-oldest house in the state. Portsmouth has the Jackson house (1664), the Warner house (1718), the John Paul Jones house (1758), the Wentworth Gardner house (1760), the Moffat-Ladd house (1763), the John Langdon house (1784) and St. John's church (1807), all open to the public in the summer months. Nearby, in New Castle, is Ft. Constitution, formerly Ft. William and Mary, where on Dec. 14 and 15, 1774, New Hampshire patriots captured powder and arms, some of which was later used at the battle of Bunker Hill. At Peterborough is the MacDowell colony for creative artists; the Saint-Gaudens memorial is at Cornish.

The state maintains 40 state parks, wayside picnic areas and historic sites, among which are the Hampton Beach, Crawford Notch and Franconia Notch parks and the Daniel Webster memorial (Franklin), Wentworth Coolidge mansion (Portsmouth) and Franklin Pierce homestead (Hillsborough) historic sites. About 805,000 ac. of forest are publicly owned, by towns, the state or the national government. The largest is the White Mountain National forest.

HISTORY

Martin Pring was at the mouth of the Piscataqua in 1603 and, returning to England in the same year, gave an account of the New England coast from Casco bay to Cape Cod bay. Samuel de Champlain discovered the Isles of Shoals and sailed along the New Hampshire coast in 1605, and much more information concerning this part of the new world was gathered in 1614 by Capt. John Smith, who in his *Description of New England* refers to the convenient harbour at the mouth of the Piscataqua and praises the country back from the rocky shore.

Colonization.—Under the leadership of Sir Ferdinando Gorges there was formed in 1620 the Council for New England, which procured from King James I a grant of all the country from sea to sea between latitude 40° and 48° N., and which made nine grants bearing upon the history of New Hampshire. The first of these grants was to John Mason, who has been called "the founder of New Hampshire," on March 9, 1622. The name New Hampshire was first applied to a grant which lay between the Merrimack and Piscataqua, and given to Mason on Nov. 7, 1629.

The first settlement of which there is indisputable evidence was established in 1623 by David Thomson at Little harbour, now in the town of Rye. Thomson was the head of a company which was organized for fishing and trading and whose entire stock was to be held jointly for five years. He built a house on Odiorne's point overlooking Little harbour, and, although he moved to an island in Boston harbour in 1626, he may have continued to superintend the business of the company until the expiration of the five-year term. At least there was a settlement there which was assessed in 1628, and it may not have been completely abandoned when colonists sent over by the Laconia company, which had received a grant on Nov. 17, 1629, arrived in 1630.

The Laconia company received its first grant under the erroneous impression that the Piscataqua river had its source in or near Lake Champlain, and its principal object was to establish an extensive fur trade with the Iroquois Indians. The company sent over colonists who occupied the house left standing by Thomson and, not far away, built Mason hall or the Great house in what is now Portsmouth, a name (for the entire settlement) that replaced Strawberry Banke in 1653. Edward Hilton with a few associates appears to have established a settlement on Dover point about the time of Thomson's arrival at Little harbour, and in the Hilton grant of 1630 it is stated that he had already built houses and planted there; as early as 1630 this settlement was named Dover.

In 1638 the Rev. John Wheelwright, an Antinomian leader who had been banished from Massachusetts, founded Exeter on land claimed to have been bought by him from the Indians. In the same year Massachusetts encouraged friendly Puritans to settle Hampton on the same purchase, and about a year later this colony organized Hampton as a town with the right to send a deputy to the general court.

Serious dissensions had already arisen between Puritan and Anglican factions in Dover, and Capt. John Underhill, another Antinomian, became for a time a leader of the Puritan faction. Puritan Massachusetts was naturally hostile to the Antinomians at Exeter as well as to the Anglicans at Strawberry Banke. Under these conditions Massachusetts discovered a new claim for its northern boundary. The charter of that colony was drafted under the impression that the Merrimack flowed east for its entire course, but now an investigation was in progress which was to show that its source in Lake Winnipesaukee was several miles north of any of the four settlements in New Hampshire. Accordingly, Massachusetts resolved to make the most of the clause in the charter which described the northern boundary as three English miles north of the Merrimack river, "or to the northward of any and every part thereof," to ignore the conflicting grants to Mason and to extend its jurisdiction over the offending settlements.

The heirs of Mason protested, but little was done about the

matter during the period of Puritan ascendancy in the mother country. Immediately after the resignation of Richard Cromwell, however, Robert Tufton Mason (a grandson of the original proprietor), who had become sole heir in 1655, began petitioning, first parliament and later the king, for relief. The commission appointed by the king in 1664 to hear and determine complaints in New England decided that Mason's lands were not within the jurisdiction of Massachusetts and made an attempt to set up a government under which his claims could be tried, but this was a failure. Mason then petitioned again, and this time Massachusetts was requested to send agents to England to answer his complaints. They arrived in Dec. 1676, and the case was tried before the lords chief justices of the king's bench and common pleas in April 1677.

Mason presented no claim to the right of government, and as to the title to the lands claimed by him the court decided that this was a question between him and the several tenants to be determined by the local court having jurisdiction in such matters. Thereupon Mason, in Jan. 1679, petitioned the king to appoint a governor who should have jurisdiction over all the lands that he claimed, and on Sept. 18 of that year New Hampshire was constituted a separate province with a government vested in a president and council appointed by the king and an assembly chosen by the people.

Provincial Period.—From 1686 to 1689 New Hampshire formed a part of the dominion of New England, which, after the first few months, was under Sir Edmund Andros as governor general. There being no provincial authority in New Hampshire at the close of this period, a convention of the leading citizens of its four towns attempted to establish one. Upon the failure of this attempt, a temporary nominal union with Massachusetts was formed, but in 1692 Samuel Allen, the assign of Mason, caused a royal government to be established with his son-in-law, John Usher, as lieutenant governor, and during the remainder of the colonial era New Hampshire was separate from Massachusetts except that from 1699 to 1741 the two had the same governor.

The boundary disputes between Massachusetts and New Hampshire were long and bitter. Both provinces granted townships within the disputed territory; Massachusetts arrested men there who refused to pay taxes to its officers, and sought to defer the settlement of the dispute. New Hampshire, being on more friendly terms with the home government, finally petitioned the king to decide the matter, and in 1737 a royal order referred it to a commission to be composed of councilors from New York, Nova Scotia and Rhode Island. This body agreed upon the eastern boundary but evaded deciding on the southern one. Both parties then appealed to the king, and in 1741 the king in council confirmed the decision of the commission in regard to the eastern boundary and established a southern boundary very favourable to New Hampshire. The western boundary was not yet defined, and as early as 1749 a controversy over that arose with New York. The governor of New Hampshire made 138 grants in the disputed territory which were rapidly settled, but there was a reluctance to incur the expense of a contest with so powerful a neighbour as New York. In 1764 New York procured a royal order declaring the western boundary of New Hampshire to be the western bank of the Connecticut river.

Revolution and Independence.—At the outbreak of the American Revolution New Hampshire had about 80,000 inhabitants, the great majority of whom were Loyalists, or Tories, during the struggle. By June 1775 the once popular governor Sir John Wentworth was a refugee; on Jan. 5, 1776, the fifth provincial congress established a provisional government; on June 15 the first assembly elected under that government declared for independence; and on Aug. 16, 1777, the important victory at Bennington, Vt., was won by New Hampshire and Vermont troops under the command of Gen. John Stark, who had a commission from New Hampshire. Six states had ratified the federal constitution when the New Hampshire convention met at Exeter on Feb. 13, 1788, to accept or reject that instrument, and so great was the opposition to it among the delegates from the central part of the state that after a discussion of ten days the leaders in favour of ratification dared not risk a decisive vote but procured an adjournment in order that certain delegates who had been instructed to vote against it might consult their constituents. Eight states had ratified when the convention reassembled at Concord on June 17, and four days later, when a motion to ratify was carried by a vote of 57 to 47, adoption by the necessary nine states was assured.

Statehood.—The American Revolution left the state heavily burdened with debt and many of its citizens threatened with debtor's prison. As a means of relief, a number of citizens demanded of the legislature the issue of paper money equal in amount to the state's debt; and, as this was refused, an armed mob numbering about 200 surrounded the meetinghouse in Exeter in which the legislature was in session, toward evening on Sept. 20, 1786. But Gen. John Sullivan (*q.v.*) was at the time president of the state; and on Sept. 21 he, with 2,000 or more militia and volunteers, captured 39 of the leaders and suppressed the revolt without bloodshed.

National elections in New Hampshire were carried by the Federalists until 1816, except in 1804 when Pres. Thomas Jefferson won by a small majority; but within this period of Federalist supremacy in national politics the Democrat-Republicans elected the governor from 1805 to 1812 inclusive except in 1809. In 1816 the Democrats won both state and national elections; and out of the transition from Federalist to Democratic control, which was effected under the leadership of William Plumer (1759–1850), a prominent politician in New Hampshire for half a century, arose the famous Dartmouth college case. As the trustees of this institution were Federalists with the right to fill vacancies in their number, the Democrats attempted to gain control by converting it into a state university and increasing the number of trustees, but when the case reached the U.S. supreme court that body pronounced (1819) the charter a contract which the federal constitution forbade the state to violate. Heretofore the Federalist regime had taxed the people to support the Congregational Church, but now the Baptists, Methodists and Universalists joined the Democrats and in 1819 this state support was abolished by the Toleration act.

Because of Daniel Webster's eloquently successful arguments in the Dartmouth college case, and because his party had favoured the support of the Congregational Church by public taxation, he became very unpopular in this his native state. Accordingly, his denunciation of Pres. Andrew Jackson's bank policy added strength to the Jacksonian democracy, and, later, his Whig connections were the greatest source of the Whig party's weakness in New Hampshire. John Quincy Adams was an intimate friend of William Plumer, the Democratic leader, and carried the state in both 1824 and 1828. The Whigs never won a national or state election and often their vote was only about one-half that of the Democrats. But the Democrats broke into two factions in 1846 over the question of slavery (*see* HALE, JOHN PARKER); the Know-Nothing party elected a governor in 1855 and 1856; and then control of the state passed to the Republican party, which held it until the presidential election of 1912 and 1916 when the Democrats won. Thereafter the state returned to its Republican tradition until 1936, 1940 and 1944 when it supported Franklin D. Roosevelt. The state government remained Republican although a Democratic governor was elected in 1922. In 1962 John W. King became the first Democratic governor elected in 40 years, and Thomas J. McIntyre the first Democratic U.S. senator in 30 years. Both were re-elected in 1966.

New Hampshire sent more than 20,000 men into the armed services during World War I. Many New Hampshire men were in the 26th or "Yankee" division. The Portsmouth navy yard was involved with building submarines and small boats and in repairing warships. About 60,000 men and women of New Hampshire served in the armed forces during World War II. The state was the site of the Bretton Woods conference (July 1944), at which representatives of 44 nations drew up plans for the International Monetary fund and the International Bank for Reconstruction and Development.

The industrial centres of New Hampshire suffered especially during the depression years of 1929–36. Many industrial plants decreased the number of employees and in some cases discon-

tinued operation, especially in Hillsborough county and in the cotton industries. The depression was less severe outside the industrial centres, and there was a considerable return of people from city areas to small towns and farms. After 1936 conditions improved, especially in Manchester, where the Amoskeag mills were partly used by many small manufacturers. Increased industrial diversification in the 1950s and 1960s saw the establishment of new plants in smaller communities, as well as in the larger cities, and New Hampshire became the only New England state to gain in manufacturing employment. At the same time the increase in nonmanufacturing employment was the highest in the region.

GOVERNMENT

New Hampshire was the first of the original states to establish a government wholly independent of Great Britain. This was designed to be only temporary but was in operation from Jan. 5, 1776, to June 2, 1784. The constitution provided for a general court consisting of a senate and a house of representatives and made the council a body advisory to the state president. The 1784 instrument was amended in 1792; with the amendments adopted in that year it is in large measure the constitution of today. For 60 years there was no change whatever, and only three amendments, those of 1852 (removing the property qualifications of representatives, senators and the governor), were adopted until 1877, when 12 amendments were adopted; the most important were those providing for biennial (instead of annual) state elections in November (instead of March), and those doing away with the previous requirement that representatives, senators and the governor "be of the Protestant religion." Five amendments were ratified in 1889, four in 1902 and four in 1912. Most important of those adopted in 1912 was one providing for the election of the governor and members of the council by a plurality instead of a majority vote. In 1956 two amendments became effective, one to permit the legislature to authorize absentee voting in primary elections and one to allow the governor to transact official business while absent from the state in line of duty.

New Hampshire is the only state in which amendments to the constitution may be proposed only by a constitutional convention, and once in seven years at the general election a popular vote is taken on the necessity of a revision of the constitution. By an act approved on April 9, 1909, provision was made for direct nominations of candidates at primaries. The government of the state was extensively reorganized as a result of legislation passed in 1949.

Executive.—There is a governor's council of five members, one from each councilor district, which has advisory duties and shares with the governor most of his powers. There is no lieutenant governor. The governor and the councilors are elected for terms of two years. The governor and council appoint all judicial officers, the attorney general, comptroller, important administrative boards and commissions and the medical referees; they have power to pardon offenses; and they may exercise some control over expenditure through the constitutional requirement of the governor's warrant for drawing money from the treasury. Reorganization legislation in 1961 placed many existing agencies in three new departments: health and welfare; resources and economic development; and safety. The governor may veto within five days, besides Sunday, after it has been presented to him any bill or resolution of which he disapproves, and a two-thirds vote of the members of both houses is required to pass over his veto.

General Court.—A senate and a house of representatives, which together constitute the general court, meet at Concord on the first Wednesday in January of every odd-numbered year, and at such other times as the governor may appoint for a special session, principally for the making of laws and for the election of the secretary of state and the state treasurer. The senate is composed of 24 members, one from each senatorial district. Membership in the house of representatives varies from not less than 375 to not more than 400 according to a plan adopted in 1931, by which towns having fewer than 600 inhabitants elect representatives according to a special schedule. In 1961 the house was reapportioned in accordance with the 1960 census, as required by the state constitution, and senate districts were redrawn for the first time since 1915. Both senators and representatives are elected for two-year terms.

Judiciary.—For the administration of justice the state has a supreme court and a superior court, and each county has a probate court. The supreme court consists of a chief justice and four associate justices; the superior court comprises a chief justice and five associate justices. The supreme court sits at Concord on the first Tuesday of every month except July and August, while the superior court holds two or three sessions a year in each of the ten counties. Each county has a single probate judge, who has jurisdiction over the probating of wills, insolvency proceedings, decisions regarding adoption of children and similar judicial functions. Supreme, superior and probate judges are appointed by the governor and council to serve until they are 70 years of age.

The legislature in 1963 established 37 district courts to consolidate 87 autonomous municipal courts, administered by a committee of three district court judges appointed by the supreme court.

Finance.—The chief sources of the income of the state government are the gasoline tax, motor vehicle and operators' licence fees, taxes on beer and taxes on or sale of liquor (sold in state liquor stores), the tobacco tax and income derived from the regulation of betting on horse racing.

New Hampshire, the first state since 1894 to establish a legal sweepstakes, adopted a sweepstakes bill in 1963, effective 1964. Receipts were earmarked for education. The law provided for $3 tickets, to be drawn in lotteries held twice a year, to be sold (at local option) at state-operated liquor stores and at the state's two racetracks.

Local Government.—Local affairs are administered by counties (ten in number), towns (townships), village districts and cities. In each county a convention, composed of representatives from the towns, meets every two years to levy taxes and to authorize expenditures for grounds and buildings whenever more than $1,000 is required. For the discharge of other county functions the qualified electors of each county elect every two years three commissioners, a sheriff, a solicitor, a treasurer, a register of deeds and a register of probate; two auditors also are appointed annually by the supreme court. The county commissioners have the care of all county property, as well as of county paupers; and once every four years they are required to visit each town of their county, inspect the taxable property therein, determine whether it is incorrectly assessed and report to the state board of equalization. In each town a regular annual meeting of the qualified electors is called on the second Tuesday in March for the transaction of miscellaneous business and the election of town officers.

POPULATION

The population of New Hampshire in 1790 was 141,885; in 1840 it was 284,574; in 1880, 346,991; in 1910, 430,572; in 1940, 491,524; in 1950, 533,242; and in 1960, 606,921. The last figure represented an increase of 13.8% over the population in 1950. The population per square mile in 1960 was 67.3, as compared with 59.1 in 1950 and with 49.6 for the U.S. in 1960.

The urban area of New Hampshire in 1940 comprised 11 cities, the smallest having a population of more than 6,000, and 7 towns (townships) classified as urban under special rule. The population of this area was 283,225, or 57.6% of the state total. The population of the same area in 1950 was 301,249, or 6.4% more than in 1940, and represented 56.5% of the state total. According to the census of 1960 the state had two standard metropolitan statistical areas—Lawrence-Haverhill (shared with Massachusetts) and Manchester. New Hampshire residents in these areas totaled 107,637, or 17.7% of the total population of the state. The urban population (1960) was 353,766, or 58.3% of the state total.

Analysis of the federal census of 1790 indicated that in that year better than two-thirds of the population of New Hampshire was of English or Welsh origin. There were small percentages of Scotch, Irish, Scotch-Irish, Germans, Dutch and French. While

foreign immigration, especially Irish, to the state began in the first half of the 19th century, the ethnic composition changed most after 1860. By the middle of the 20th century French-Canadians represented one of the largest ethnic groups in the state, along with the English-Welsh. In the order of size the other ethnic groups are English, from both England and Canada, Irish, Poles, Greeks, Scotch, Italians, Germans, Russians, Swedes,

Finns, Norwegians, Portuguese, Austrians and Hungarians.

While there was a large migration of younger people out of the state, this was partly offset by the choice of New Hampshire as a place for retirement, so that during the 20th century the population was relatively stable.

The number of households in 1960 was 180,020, as compared with 149,475 in 1950 and 135,960 in 1940. The average population per household had declined from 3.7 in 1940 to 3.4 in 1950 and to 3.2 in 1960.

The population of the state was distributed by colour and nativity in 1960 as follows: 92.2% native white; 7.3% foreign-born white; and 0.5% nonwhite. Of the 44,418 foreign-born white, 60.0% were born in Canada, including 42.9% Canadian-French alone. There were 97.8 males per 100 females in the native white population and 81.4 in the foreign-born; 10.7% of the population was 65 years old or over; and 54.1% of the population 14 years old and over was in the labour force. Of the total number of employed males, 4.3% was engaged in agriculture, 8.7% in construction, 41.2% in manufacturing, 21.5% in transportation and trade and 17.8% in services of various kinds.

EDUCATION

New Hampshire formed a part of Massachusetts when, in 1647, the general court of that province passed the famous act requiring every town in which there were 50 householders to maintain a school for teaching reading and writing, and every town in which there were 100 householders to maintain a grammar school. During the 19th and early part of the 20th century various experiments for improving the public-school system were tried.

The public-school system has at its head a state board of education composed of seven persons appointed by the governor and council. The administrative work is carried on by a commissioner of education, appointed by the board for an indefinite term, a deputy commissioner, nominated by the commissioner and appointed by the board, and a director of technical institutes, appointed by the board. Each town is constituted a school district, and some special districts are organized under special acts of the legislature. For the purpose of inspecting and supervising all institutions in which state money is spent, the several school districts in the state are combined into supervision unions consisting of one or more school districts. The schools are maintained chiefly out of the proceeds of a district school property tax.

All children between the ages of 8 and 16 are required to attend either a public or an approved private school for the full term unless they are more than 14 years old and have completed the studies prescribed for the elementary schools, or have been excused by the school board on account of physical or mental infirmity. State aid for the education of mentally retarded children in local public schools was authorized in the 1960s.

The only state institutions of higher education are the Plymouth Teachers college (1870) at Plymouth, the Keene Teachers college (1909) at Keene and the University of New Hampshire, organized in 1866 at Hanover as the New Hampshire College of Agriculture and the Mechanic Arts and moved to Durham in 1893. By an act of the legislature it became a university in 1923 and offers undergraduate work in agriculture, engineering and liberal arts. There is also a graduate school offering both the master's and the doctor of philosophy degrees. Other institutions of higher learning in the state are Dartmouth college (nonsectarian, 1770) at Hanover (*q.v.*); Saint Anselm's college (Roman Catholic, 1889) at Manchester; Mount St. Mary college (Roman Catholic, 1934) at Hooksett; Rivier college (Roman Catholic, 1933) at Nashua, New England college (nonsectarian, 1946) at Henniker; and Colby Junior college for women (academy, 1837; college, 1928) at New London.

HEALTH, WELFARE AND CORRECTIONS

The state charitable and correctional institutions include the New Hampshire school for feeble-minded children at Laconia (*q.v.*); the New Hampshire soldiers' home at Tilton; the New Hampshire industrial school at Manchester (*q.v.*); the New Hampshire hospital for the mentally ill, and the state prison at Concord; and the New Hampshire sanatorium for tuberculosis patients at Glencliff in the town of Warren. The state also makes annual appropriations for the care and education of blind and deaf and mute persons in institutions outside the state.

ECONOMY

Agriculture.—Agriculture in New Hampshire was greatly modified in the 20th century, the production of vegetables, fruits, dairy products, poultry and eggs largely supplanting the production of cereals. The total acreage in farms decreased from over 3,000,000 in 1910 to less than 1,500,000 in the second half of the century. During the same period the number of farms decreased from 27,000 to fewer than 7,000, but the average acreage per farm increased from 120 to 143. Nearly all farms are worked by owners or part owners. Livestock, poultry and their products account for about 75% of annual value of farm products. Dairying, long an important New Hampshire industry, was supplanted by poultry and poultry products as the major source of farm income. Apples, potatoes and hay are the principal crops.

Forests and Fisheries.—Except on the summits of the higher mountains, New Hampshire was originally an unbroken forest of which the principal trees were white pine, hemlock, sugar maple, yellow birch, beech, red oak and white oak in the south, red spruce, balsam and white birch on the upper mountain slopes, and red spruce, white pine, sugar maple, white spruce and white cedar in the other parts of the north. The white pines of New Hampshire were an important source of masts for the British Royal Navy during the colonial period. Even in the second half of the 20th century nearly 85% of the state was forested. Two-thirds of the timber harvested was sawlogs, one-fifth was pulpwood and most of the rest was firewood. One-sixth of the state's commercial forest land is publicly owned, most being in the White Mountain National forest.

New Hampshire, with only one coastal county (Rockingham), ranks sixth among the New England states in its fishing yield.

Minerals.—Formerly granite was the most important of the mineral products of New Hampshire. New Hampshire granite was used for building as early as 1623, and at the beginning of the 20th century New Hampshire was one of the leading states in granite quarrying. But the use of steel and concrete in building caused a rapid decline in the industry, and by the second half of the 20th century New Hampshire's minerals, in order of value, were sand and gravel, stone, mica and feldspar. Sand and gravel, which account for about half the state's mineral output (value), are produced in nearly all counties. Stone, the second most important mineral, is quarried in Rockingham, Merrimack, Grafton, Hills-

borough, Carroll and Coos counties. Mica, first mined in Grafton, Grafton county, in 1803, was later found in other parts of the state in such quantities that for 60 years during the 19th century New Hampshire was the largest producer of mica in the United States. In the 1960s large reserves of thorium were reported in the state.

Manufactures.—Since the beginning of the 20th century New Hampshire's chief source of employment and income has been in manufacturing. There were 1,618 manufacturing establishments in 1904, and 50 years later there were 1,609 (1954 census of manufactures). For the same period the number of persons employed increased slightly, from 68,032 to 77,071, the value added by manufacture multiplied, from $50,400,000 to $408,800,000, and payrolls rose from $30,700,000 to $245,300,000. By the 1960s the number of plants was below 1,200, but the number of employees had increased to well over 80,000 and payrolls to over $350,000,000. Until the late 1940s textiles and leather products (chiefly boots and shoes) were the major manufactures. After that time some cotton and woolen mills ceased operation or moved south. New industries, especially the production of electrical and electronic goods, partly replaced textiles. Other important industries in New Hampshire are nonelectrical machinery, pulp, paper and paper products, lumber and wood products, and printing and publishing. Most of the manufacturing centres of the state are south of Lake Winnipesaukee. An exception is Berlin, the chief manufacturing centre north of the White mountains, important for its manufacture of paper and wood pulp.

Transportation and Communications.—Most of the railways in the state are owned or leased by the Boston and Maine. This company was the first to operate a railway within the state, service being maintained between Boston, Mass., and Dover, N.H., as early as 1842. Railway mileage decreased from more than 1,200 mi. in the 1920s to less than 1,000 mi. in the second half of the 20th century. There were over 14,000 mi. of public roads, of which better than two-thirds were surfaced.

Ten daily newspapers and about 40 weeklies are published in New Hampshire. The *New Hampshire Gazette*, founded in 1756, is claimed to be the oldest continuously published newspaper in the United States; it is printed as a part of the *Portsmouth Herald*. There are two television stations in the state, and broadcasting facilities for two out-of-state stations are located in Winchester and on top of Mt. Washington. Of the 25 radio-broadcasting stations, two are both AM and FM.

NEW HARMONY, a town of Posey county in southwestern Indiana, U.S., about 22 mi. N.W. of Evansville is situated on the Wabash river. In the 19th century it was the scene of two famous experimental co-operative communities.

The site, a tree-studded meadow safely above flood stage of the Wabash, was occupied by prehistoric Mound Builders and later became a camping ground for Piankashaw and Kickapoo Indians. In 1814 it was bought by the followers of George Rapp, a German Pietist preacher who had led disciples to the U.S. in 1803. Their original colony in western Pennsylvania had prospered but Rapp elected to move westward. On the Wabash the Rappites laid out their town and named it Harmonie. They planted the rich land, set out orchards and vineyards and built residences, two churches, shops and factories. They also built separate dormitories for men and women because "Father" Rapp advocated celibacy, though the practice was not enforced. Soon a winery, brewery, distillery, looms, smithy, hattery and other industries to supply frontier merchandise were in production. Rappite traders carried their products on all midwestern rivers, and their trade-mark, the Rappite rose, soon came to be a guarantee of quality.

But neighbouring frontiersmen were suspicious of clannish, German-speaking Harmonie and its celibacy; or perhaps they were jealous of its prosperity. Besides, the market was smaller than Rapp had expected, and by 1824 Rappite leaders were ready to sell out and return to Pennsylvania. The buyer was Robert Owen (*q.v.*), British reformer who came to the U.S. to found a perfect co-operative community which would be based on his plan for the ultimate salvation of all mankind through "rational" thinking, co-operation and free education. In 1825 he bought Rapp's ready-built Harmonie with cash and notes, renamed it New Harmony and invited all to join him in Utopia and live at his expense until they could carry out his program and become self-supporting. William Maclure (*q.v.*), a geologist, businessman and philanthropist, who joined Owen and agreed to finance the schools, brought and paid his own teachers and supplied scientific equipment and a library.

Owen was adept at publicity. Myriads of persons talked of joining him and more than 1,000 actually arrived. With few exceptions, however, they were incompetent, greedy or daydreaming misfits. They ate Owen's rations, argued about their own government and debated the merits of Owen's "new system" while the farms and factories lay idle.

By May 1827 Owen's available cash had been expended on payments for the land and groceries for his followers. Maclure paid the last Rappite note in 1828 and Owen returned to Great Britain. Maclure's teachers and the best of Owen's recruits, including his sons, stayed on and developed one of the most notable pre-Civil War cultural centres in the U.S.

In the 20th century New Harmony is basically an agricultural community. Although its population has remained less than 2,000 (1,121 in 1960), its many original Rappite buildings have made it a charming but little understood monument to an interesting phase of the U.S. past. (R. E. BA.)

NEWHAVEN, a seaport and urban district in the Lewes parliamentary division of East Sussex, Eng., 7 mi. S.S.E. of Lewes by road, on the English channel at the mouth of the Ouse; after a great storm in 1570 the river shifted westward from its original outlet at Seaford to enter the sea at Meeching, which became known as the "new" haven. Pop. (1961) 8,419. Area 2.8 sq.mi. A fort dominates the entrance to the harbour, which was first granted to Newhaven in 1713. It is the English terminus (since 1843) of a cross-channel steamer service to Dieppe, and there is a large trade with the continent. There is some light industry (on a factory estate) and boatbuilding. The sandy beach offers bathing facilities. St. Michael's parish church is one of the earliest Norman churches in England.

NEW HAVEN, a city and port of entry in southwestern Connecticut, U.S., on Long Island sound at the mouth of the Quinnipiac river, is about 70 mi. E.N.E. of New York city. It is the seat of Yale university (*q.v.*).

It was originally settled in 1638 by about 500 English Puritans under the leadership of John Davenport and Theophilus Eaton. Most of the settlers had come from England the previous year and had wintered in the Massachusetts Bay colony. Originally called Quinnipiac, an Indian word meaning "long water land," in 1640 the settlement was renamed for the port city of Newhaven in England. In 1643 New Haven and three adjacent towns, together with Stamford, 30 mi. W., and Southold on Long Island, joined to form the New Haven colony, of which Eaton was governor until his death in 1658. Strong Puritan sympathies made the colony a refuge, in 1661, for Col. Edward Whalley and Col. William Goffe, two officers in Cromwell's army, who had been members of the court that condemned Charles I and fled to New

England seeking sanctuary. Although the political consequences of this sympathetic action are disputed, within four years New Haven colony was assimilated into Connecticut colony, which had been based on Hartford and enjoyed a royal charter.

In 1701, however, New Haven became co-capital with Hartford, a position it maintained in both colony and state until 1873, when Hartford became the sole seat of government. A collector of the port was appointed in 1760 and thereafter a flourishing shipping trade grew up with the West Indies, Newfoundland and other American ports. During the American Revolution New Haven, strongly supporting the Continental cause, was sacked (July 5, 1779) by Loyalist forces under Gen. William Tryon, colonial governor of New York. Tryon, however, was driven off before he could burn the town. New Haven was incorporated as a city in 1784 and, following the War of 1812 during which many local seafarers turned to privateering, trade with ports throughout the world sprang up and manufacturing began to make itself felt as an important part of the economy.

Around 1830 immigrants began to arrive from Ireland and Bavaria. A wave of Italian immigration commenced in 1870, and a decade later, partly as a result of pogroms in Russia, eastern European Jews began arriving in considerable numbers. Slavery was gradually eliminated in Connecticut after 1784, and by 1820 there were over 600 Negroes in New Haven; in the decades before the American Civil War the city was an important centre of abolitionist sentiment.

These waves of immigration greatly facilitated the economic growth of the area, as did the proverbial Yankee ingenuity. New Haven was where Eli Whitney developed interchangeable parts for firearms, thus helping to usher in the principle of mass production; where Charles Goodyear discovered vulcanized rubber; and where Samuel Colt improved his invention of the repeating revolver. In the second half of the 20th century New Haven industries included shipbuilding and the manufacture of firearms, ammunition, aircraft parts, hardware tools, rubber goods, watches, clocks, textiles and paper products.

The cultural life of New Haven is a blend of contributions from Yankees and later immigrants. The Puritans' deep interest in education led to the founding in 1660 of Hopkins grammar school, which still exists. Yale university, founded (1701) as the Collegiate School of Connecticut in Saybrook, moved to New Haven in 1716. Other institutions of higher learning in New Haven include Albertus Magnus college (Roman Catholic, 1925) for women; Southern Connecticut State college, founded (1893) as New Haven Normal school; and New Haven (junior) college (1920).

Although much of the area's cultural activities depend upon Yale's art gallery, drama and music schools, and its famed Peabody Museum of Natural History, New Haven has its own symphony orchestra, and in 1958 it instituted a community-wide festival of arts. For years Broadway plays and musicals have used the old Shubert theatre for public tryouts before opening in New York.

Pop. (1960) 152,048; standard metropolitan statistical area (New Haven, Branford, East Haven, Guilford, Hamden, North Haven, Orange, West Haven and Woodbridge) 311,681. In 1963 Bethany and North Branford towns, pop. (1960) 9,155, were added. For comparative population figures *see* table in CONNECTICUT: *Population.* (R. A. DL.)

NEW HEBRIDES, a western Pacific island group consisting of 12 principal islands lying about 500 mi. W. of Fiji and 250 mi. N.E. of New Caledonia. It has a multiracial society governed jointly by France and Great Britain. Area 5,700 sq.mi.; pop. (1960 est.) 60,474, including Europeans, Vietnamese, Chinese, Tahitians, Wallis islanders, New Caledonians and Melanesians.

Physical Geography.—Diversification characterizes the relief, which ranges from rugged mountains and high plateaus to rolling hills and low plateaus, with coastal terraces and offshore coral reefs. Sedimentary and coral limestones with volcanics preponderate and the frequent earthquakes indicate structural instability (*see* also PACIFIC ISLANDS). Some islands comprise a single volcanic cone and there are three active volcanoes. The climate is hot and wet at all seasons, though eastern slopes are drier than western, as the southeasterly trades are the prevailing winds. Much of the group is covered by dense rain forest, but drier regions have savanna woods. Black earths and brown forest formations appear to be the principal soil groups. Abundant bird life contrasts with the sparse land fauna.

The People.—A complex settler community of Europeans, Asians and Polynesians, legally divided into French and British, has been imposed on the native Melanesians. The Europeans are dominant. The Asians are prosperous, the Chinese socially assimilating to the Europeans and contrasting with the isolationist Vietnamese who are former coolies. Polynesian Wallis islanders entered the group as plantation labourers in the mid-20th century.

Traditionally organized in mutually hostile tribes, the natives now seek adjustment to European intrusion. Remote villages with few European contacts, apart from missionaries, have achieved temporary adjustment, but most natives are resentful of white wealth; hence the growth of antisettler cults to acquire power either through neopagan rituals or elaborate organization. Resentment is less and adjustment better around Vila, the capital, where the natives are acquiring greater wealth. Basically the Melanesians want higher standards and a voice in their own destiny.

History.—Originally found by the Portuguese navigator Pedro Fernandez de Quirós (1606), rediscovered by the French explorer Louis de Bougainville (1768) and chartered by the English captain James Cook (1774), the New Hebrides were exclusively British commercially until 1870. Subsequently French interest developed rapidly, leading to a policy of mutual exclusiveness (convention of 1878), rudimentary joint control (mixed naval commission, 1887), and finally the condominium (1906 protocol). In 1940 the local French were Gen. Charles de Gaulle's first overseas adherents and the group escaped Japanese invasion, becoming a major Allied base.

The first settlers were sandalwooders (1843) and missionaries (1848) followed by cotton planters about 1868. Cotton gave way to bananas and coffee after 1880, only to be replaced by coconuts and maize (corn) in the first decade of the 20th century. Unprecedented prosperity, based on copra, cocoa and coffee produced by cheap Vietnamese labour, occurred in the 1920s, but this vanished during the world depression. Although only a minor revival occurred before World War II, the postwar period witnessed a tremendous boom.

Government.—While exercising joint sovereignty over the indigenous people, the corulers retain separate responsibility for their nationals. Under the 1914 protocol (ratified 1922) authority is vested in the French and British high commissioners who are represented in Vila by resident commissioners. These officials jointly control the condominium administration, whose sphere is defined in the protocol and by their respective national authorities. This tripartite arrangement is continued into local affairs by parallel national district agents, jointly supervising village chiefs or councils of elders. Jurisdiction over native and land cases lies with the condominium courts centring on the joint court under a neutral president, but disputes involving settlers are taken before the appropriate national court. Representative institutions are confined to a few elected village councils and the French national advisory council.

The Economy.—The economy of the New Hebrides is based primarily on copra production. The group is, however, a marginal copra producer suffering from high costs, low productivity and distance from the market. Although there is a labour shortage and wages are the highest in the Pacific, the planters continue to rely on obsolete cultivation practices depending on ample cheap labour while native methods are extremely primitive. Equally poor processing causes dependence on the unrewarding French market for soap-grade copra. Improvement is slow as boom profits were largely exported and capital is therefore short. Copra (44% native-produced) provides 85% of the condominium's exports, but some cocoa (17% native-grown) and coffee are also planted.

New Hebridean commerce is dominated by two concerns, one

Australian and the other French. Australia supplies 59% of the condominium's imports, largely foodstuffs, gasoline and textiles, while 95% of the exports are taken by France. Vila, handling 49% of the total trade, and Santo are the group's ports of entry.

NEW IRELAND, an island of the Bismarck archipelago (*q.v.*), is situated to the north of New Britain, from which it is separated by St. George's channel. With the adjacent islands it forms an administrative district of the Australian Trust Territory of New Guinea (*see* NEW GUINEA). Area (including adjacent islands) 3,800 sq.mi. Pop. (1962) 40,659, of whom a small number are European or Chinese. The island is 220 mi. long but very narrow. The southern portion attains a breadth of 30 mi. but the prolongation which extends northwestward for almost 130 mi. is nowhere wider than 15 mi. and in places narrows to about 5 mi. across. Unlike New Britain (*q.v.*) the island contains no active volcanoes, but it is rugged and mountainous, especially in the south where the Rossel mountains rise to 6,430 ft. Limestone mountains and plateaus occupy much of the long northwest peninsula, but there is generally a fringe of coastal plain, of raised coral or alluvium, and at the constrictions the coasts are separated only by low saddles.

Commercial development is practically confined to copra production, especially on the east coast. In addition to the plantations (more than 72,000 ac. in the 1960s) there has been an increasing production from native groves. Most of the inhabitants live in the north of the island. The administrative centre and chief port is Kavieng at the northern end connected by a motor road along the east coast to Samo. The southern portion of the island is administered from Namatanai, on the east coast.

New Ireland was first discovered by the Dutch navigators Jacob Le Maire and William Schouten in 1616. An attempt to colonize it failed in 1880. Annexed by Germany in 1884, it was renamed New Mecklenburg. After World War I it was mandated to Australia. In Jan. 1942 it was occupied by the Japanese; it was reoccupied by Australia in 1945. (D. W. F.)

NEW JERSEY, usually referred to as the "Garden state" because of its many truck farms, is located along the eastern seaboard of the United States about 38° N. of the equator. It is bounded on the north by New York, on the west by Pennsylvania, on the south by the Delaware river bay which separates it from Delaware, and on the east by the Atlantic ocean and the Hudson river. New Jersey ranks 46th in size among the states and measures 166 mi. in length from the northernmost to the southernmost extremities, 60 mi. in width at its greatest girth and 32 mi. at its narrowest. It has a total area of 7,836 sq.mi., of which 315 sq.mi. consist of lakes and other inland water areas. New Jersey, one of the 13 original colonies, became the third state of the union on Dec. 18, 1787; its state capital is Trenton. The red oak has been adopted as the state's official tree, the purple violet as the official flower and the eastern goldfinch as the official bird. The state's flag is buff-coloured with the blue seal of the state in its centre.

PHYSICAL GEOGRAPHY

Physical Features.—Though New Jersey is small in area, it is geologically interesting. Viewed from above it looks like a series of descending steps from the mountains in the northwest to the tidal marshes along the eastern and southeastern seacoasts. It has been estimated that the state's land masses are more than 1,000,000,000 years old and record the geological cycle of rock formation and decay through the phases of mountain building, erosion, flooding, re-emergence, the Ice Age and the subsequent breakdown after the glaciers receded. The Appalachian mountains cut across the northwest corner of the state. These mountains vary from 1,200 to 1,500 ft. above sea level and contain High Point (1,803 ft.), the state's highest elevation. Alongside this mountain range, but just south and east of it, is a small belt of highlands about 400 ft. lower in average elevation, which covers about one-seventh of the state's area. The remainder of the northeastern and north-central portions of the state are a lowland area that varies between 200 and 800 ft. in elevation. The rest of the state, that is, somewhat more than half of it (4,400 sq.mi.), consists of a flat coastal plain mostly less than 100 ft. above sea level, of which about one-eighth is tidal marshland, usually flooded at high tides, lying between the barrier beaches of the coastline and the actual mainland. The average mean elevation of the state is only 250 ft. above sea level.

The four "steps" or belts correspond closely to the major geological epochs of land formation. The great glaciers of the Ice Age covered a little more than one-third of the state and left large deposits of debris in an irregular line roughly from just west of Staten Island southwestward to Pennsylvania.

The Delaware river, from its junction with the Neversink river to the capes, flows along the western and southern borders of the state for 245 mi. The Hudson river drains only a small part of the state, but has contributed materially to its economic development. The principal stream of the highlands and Triassic lowland, the Passaic, rising in Morris county, passes through a gap in the traprock at Little Falls, descends 40 ft. and at Paterson drops 70 ft. as the Great falls of the Passaic and, bending southward, empties into Newark bay. The Hackensack river enters the state about 5 mi. W. of the Hudson, flows almost parallel with it and empties into Newark bay, having a length of 34 mi. The Raritan, the largest stream lying wholly within New Jersey, flows eastward through the centre of the state. Among the highlands are numerous lakes of which the largest are Lake Hopatcong, in Morris and Sussex counties, and Greenwood lake, partly in New York and partly in New Jersey.

Soil.—The soils of New Jersey generally follow the "steps" of elevation that descend from the mountains in the northwest to the coastal plain in the southern and eastern parts of the state. In the northwestern mountains the soil is regarded as heavy; that is, containing large amounts of sandstone and limestone. The soil of the northern highlands area is also heavy, but includes granite loams and gneiss in addition to limestone, while the southern highlands soil has large quantities of shale and red sandstone as well as traprock. The lowlands tend to be a mixture of loams, sand loams and greensand marl. The coastal plain is composed mostly of sand soils with pockets of loam.

Climate.—New Jersey's climate varies greatly between the northern and southern parts of the state, largely because of the higher elevation in the north and the dominating effect of the Atlantic ocean over the southern coastal plain and lowlands. The average annual temperature is about 50° F. in the extreme north and about 55° in the extreme south, less than 200 mi. away. In the north the winter temperatures average about 28° F. while the summer averages 70°. In southern New Jersey the winter temperatures average about 35° and the average summer temperature is 71°. For the state as a whole the winter temperatures average just above the freezing point (33°) and in the summer generally tend to be reasonably comfortable (average of 74°) though high humidity prevails almost all year round.

The length of the growing season in the state is about 155 days in the northwest and about 203 days along the southeastern coast. The annual average rainfall is about 46 in. for the state as a whole, though southern New Jersey averages only 36 in. while northern New Jersey usually exceeds 50 in.

Vegetation.—The vegetation of northern New Jersey does not vary much from that of the surrounding states, and in the south, especially in the pine forests, there are many examples of plant life common to North America. Plants commonly found in the state include the honeysuckle, beach plum, wild azalea, wintergreen and cardinal flower. Slightly over 30% of the state consists of wasteland, much of which is in scrub forests.

About two-fifths of the state's area is in forest growths of various kinds. The largest forest region is the pine barrens, which covers more than 1,200,000 ac. and includes a very large part of the southern half of the state. The pine barrens is composed of many varieties of pine, including areas of badly stunted growth and white cedar in the swamps. The next largest forest area

comprises about 500,000 ac. in the major river valleys. The principal growth is oak, but there are also birch, maple, ash, elm, walnut and chestnut. Finally, in the mountains of the northwest and highlands of the north central part of the state, there are about 300,000 additional acres of forest lands in which almost all trees common to North America may be found. Throughout all of these forests are ferns, many herbaceous plants, holly and the usual wild flowers native to the eastern United States.

Animal Life.—In the pine forest and the mountains deer, bear and wildcat are common. Other animals often seen in New Jersey are squirrels, chipmunks, rabbits, opossums, raccoons, foxes, muskrats and woodchucks. Snakes also are commonly found, most especially in the south. Many migratory birds pass over the state as do the shore and land birds which populate the southern forests.

State Parks, Forests and Historic Sites.—New Jersey has established 23 state parks with an area totaling approximately 27,000 ac. In the parks are preserved sites of historic significance, native plants and animals and sanctuaries for wildlife. Hunting is not allowed, although fishing is permitted under state regulations. Some of the parks are Allaire (1,277 ac.) in Monmouth county, Cheesequake (975 ac.) in Middlesex county, High Point (10,935 ac.) in Sussex county, Parvin (1,025 ac.) in Salem county, Ringwood Manor (579 ac.) in Passaic county and Washington Crossing (372 ac.) in Mercer county.

Eleven state forests, with a total area of more than 150,000 ac., occupy the least-developed sections, such as the mountain area in the north and the lowlands in the pine barrens. These forests provide facilities for camping, picnicking, bathing and water sports, and serve as laboratories for the study of wildlife and also forest plantings. The Wharton tract, covering more than 90,000 ac., was acquired by the state in 1954 as a state forest. Other forests are Bass River forest (9,270 ac.) in Burlington and Ocean counties, Lebanon forest (22,216 ac.) in Burlington and Ocean counties and Stokes forest (12,429 ac.) in Sussex county. The state parks and forests are under the supervision of the department of conservation and economic development.

The state's historic sites serve as reminders of New Jersey's stirring past. A monument at Freehold commemorates a battle of the Revolutionary War fought on June 28, 1778, in which Molly Pitcher figured. Other signs of the Revolutionary period include the Old Barracks at Trenton, built in 1758 to quarter British troops and later occupied by the Continental army; the Wallace house at Somerville, which served as General Washington's headquarters during the winter of 1778–79; and the Morristown National Historical park, which includes Fort Nonsense and Jockey Hollow with replicas of the quarters occupied by the Continental army during two winters. Another famous landmark is the Berrien house at Rocky Hill, where Washington wrote in 1783 the farewell address to his troops. The Continental congress met for a time in Nassau hall (built in 1756) at Princeton university. Another important colonial landmark was the home of Col. William Richards, restored in 1874 by Joseph Wharton. The Edison research laboratory, established in 1887 by Thomas A. Edison at West Orange, became a national monument in 1956.

HISTORY

Exploration and Settlement.—The Lenni Lenape Indians (called Delawares by the first settlers), a tribe of the Algonkian group, early inhabited the region now known as New Jersey. In 1758 the dwindling tribe moved to a reservation at Brotherton, now called Indian Mills, in Burlington county.

In 1524 Giovanni da Verrazano, a Florentine explorer who sailed for France, touched the New Jersey shore, but it was not until 1609 that Henry Hudson, employed by the Dutch East India company, dispatched a party to explore Newark bay. He then sailed his ship the "Half Moon" up the river now known as the Hudson and established Dutch claims. Nine years later a Dutch trading post was located at Bergen. Cornelius Jacobsen Mey in 1614, and later Cornelius Hendricksen, explored the Delaware river. By 1623 New Netherland (that part of North America between New France, or Canada, and Virginia) was established as a province, and soon Fort Nassau was built at the present site of Gloucester. Fifteen years later Swedish settlers were trading at Fort Christina on the west bank of the Delaware near the present site of Wilmington.

Colonial Rule.—In 1664 King Charles II of England granted to his brother James, duke of York, the vast Dutch holdings that included the present state of New Jersey. The region between the Hudson and Delaware rivers was soon transferred by the duke to John, Lord Berkeley, and Sir George Carteret. By this grant the duke of York created the colony of New Jersey or New Caesarea, named in honour of Carteret, a Royalist, who as its governor had defended the Isle of Jersey for the crown during the English Civil War.

To attract immigrants the proprietors in Feb. 1665 published their "Concessions and Agreements" by which they provided for a governor, a governor's council and an assembly chosen by the freemen and empowered to levy taxes. Meanwhile Gov. Richard Nicolls of New York, ignorant of the grant to Berkeley and Carteret, had confirmed sales to settlers of sites which later became Elizabethtown, Middletown and Shrewsbury. In 1669 trouble between the proprietary governor and the inhabitants of the last two towns over quitrents caused the nullification of the grants made by Nicolls. Four years later the Dutch fleet brought New Jersey under Dutch control, but England reacquired it by the treaty of Westminster, Feb. 9, 1674. The eastern half of the state was restored to Carteret's proprietorship. Berkeley had sold to John Fenwicke and Edward Byllynge, Quakers, his lands which subsequently were acquired by William Penn, Gawen Lawrie and Nicholas Lucas.

By the "quintipartite deed" of July 1676, the province east of a line from Little Egg harbour to a point on the Delaware river in 41° 40′ N. (East Jersey) was assigned to Carteret, and that west of this line (West Jersey), about five-eighths of the whole, to the Quaker associates (first Quaker colony in America). In 1677, 230 Quakers from London and Yorkshire founded a settlement which became Burlington. West Jersey was never actually governed under the liberal "Concessions and Agreements," presumably drafted by Penn, because Byllynge's title to the land conveyed to him alone the right to govern. Byllynge commissioned Samuel Jennings as deputy governor with the consent of the other proprietors. Jennings called the first assembly which passed fundamental laws providing for a governor and council. In 1680, after Philip Carteret, the governor of East Jersey, had been forcibly carried to New York and imprisoned, Sir Edmund Andros appeared before the East Jersey assembly as governor, but the deputies refused to pass the measures he recommended. A New York jury freed Carteret of charges of illegal exercise of authority and the duke of York recalled Andros from New York. In 1682 the province, which Sir George Carteret had bequeathed to eight trustees to administer for the benefit of his creditors, was purchased at public auction by Penn and 11 associates for £3,400. Each sold one-half of his share, thus making 24 proprietors whom the duke of York authorized to govern the province. They directed the appointment of the American Board of Proprietors (1684) who with the deputy governor cared for such proprietary interests as approval of legislation and grant of lands. In 1686 Perth Amboy, the newly created port of East Jersey, became its seat of government. After becoming king in 1685, James II—determined to unite New York, New Jersey and the New England colonies—extended accordingly the authority of Andros, now viceroy of New England.

In April 1702 the proprietors transferred to the crown all of their rights of jurisdiction but retained their rights to the soil. The provinces of East and West Jersey were then united and governed as a royal province. Until 1738 New York and New Jersey had the same governor; thereafter each had its own. The legislature met alternately at Burlington and Perth Amboy until 1790 when Trenton became the capital.

The diverse population of the colony grew steadily and at the time of the Revolutionary War it was estimated at 138,000. Those settlers who previously had acquired land grants were in constant conflict with the proprietors. A continuous discord pre-

vailed between the royal governors and the assemblies, which, coupled with British commercial restriction, became a factor favouring the Revolution.

The Revolution.—New Jersey was active during the Revolutionary War period. In 1774, following the action of the other colonies, a committee of correspondence and local committees were organized to disseminate information, and on July 21 a provincial congress met at New Brunswick and selected delegates to the first continental congress at Philadelphia. In June 1776 Gov. William Franklin was arrested by the provincial congress, thus ending the royal authority. A constitution was adopted on July 2, 1776. New Jersey's people were divided. The loyalists, or Tories, had early organized six battalions, while other groups supported the patriots. British sympathizers in the Revolution engaged in guerrilla action, and their "pine barren robbers" conducted raids in southern New Jersey.

Important battles of the war were fought in New Jersey. Late in 1776 General Washington, commander in chief of the Continental forces, unable any longer to hold the lower Hudson, retreated to the Delaware near Trenton and, by commandeering all available boats, won for his dispirited troops the river as defense against their pursuers. Recrossing with 2,500 men on Dec. 25, he surprised three Hessian regiments next morning and took 1,000 prisoners and 1,000 stands of arms. Outmaneuvering Lord Cornwallis, the British commander, Washington defeated a detachment of Cornwallis' army at Princeton on Jan. 3, 1777. As the British army was retreating from Philadelphia to New York, Washington's forces engaged it in the indecisive battle of Monmouth on June 28, 1778. During the war the Continental army crossed the state four times, and Washington twice had his winter quarters at Morristown.

Delegates from the state attended both the Annapolis convention (*q.v.*) in 1786 and the Constitutional Convention at Philadelphia in 1787. At the latter, New Jersey leadership sponsored the small states' position (New Jersey plan) in opposition to the Virginia or large states' plan. The New Jersey plan left its imprint in the provision of the federal constitution for equal representation for large and small states in the national senate and for the supremacy of federal law (*see* CONSTITUTIONAL CONVENTION [U.S.]). On Dec. 18, 1787, New Jersey became the third state to ratify the federal constitution.

19th Century.—On Aug. 22, 1787, John Fitch demonstrated on the Delaware the first steamboat, and 31 years later the Vail works near Morristown built the machinery for the "Savannah," the first steamboat to cross the Atlantic. In 1794, under the auspices of Alexander Hamilton's Society for the Establishment of Useful Manufactures, chartered by the legislature in 1791, a calico-printing factory inaugurated at the Great falls of the Passaic the first factory town in the U.S., now Paterson. In 1806 the first interstate railroad bridge was opened at Trenton. This material progress was interrupted by the War of 1812, which in the beginning was very unpopular, especially among the Quakers. After the war the construction of the Morris (1824–38) and the Delaware and Raritan (1826–38) canals and the completion of New Jersey's first railway, the Camden and Amboy (1834), provided facilities for a widespread industrial development.

Agitation for democratic reform culminated in a constitutional convention at Trenton (May 14–June 27, 1844), which drafted a new frame of government by which New Jersey abolished property qualifications for suffrage, modified the basis of representation in the assembly, separated the legislative, executive and judicial powers and provided for the direct election of the governor.

Opinion in New Jersey was divided on the question of slavery. The underground railroad transported fugitives to freedom, but when the American Civil War broke out, 18 people in New Jersey were legally still slaves. In 1860 three of the state's electoral votes went to Democrat Stephen Douglas and four to Abraham Lincoln, and New Jersey was one of the three states which voted for Lincoln's opponent in 1864. The state furnished 88,305 men for the Union cause and incurred extraordinary expenditures to the amount of $2,894,385. Ratifications of the 13th and 15th amendments were each first refused by the respective legislatures before being voted by their successors in which the Republican party had gained a majority; in 1868 the Democratic legislature sought in vain to withdraw the ratification of the 14th amendment voted by its Republican-controlled predecessor.

A bitter railway war followed the Civil War. The Pennsylvania railroad was charged with virtually monopolizing the route between New York city and Philadelphia as a result of a 999-year lease through which it had gained control of the properties of companies previously granted monopolistic privileges. In 1873 the state opened the route to other railroads. This same period was marked by great cultural, scientific and industrial development.

Modern Times.—With no limit fixed either to capitalization or to bonded indebtedness, and with a policy of encouraging the holding company structure, coupled with a tax rate lower for large than for small corporations, New Jersey by 1904 had chartered 3 of the 7 largest trusts and had "mothered" 150 of the 298 next largest business organizations in the U.S. A growing concern over the effects of industrialism led to direct primaries (1907, 1911), a new ballot form (1911), the election of Woodrow Wilson as governor (1911–13) and the passage in 1913 of the "Seven Sisters" acts for eliminating the power of trusts to create monopoly, limit production, fix prices and restrain trade. New laws limited public service franchises to 20 years, subject to municipal referendum.

Political power has usually been shared by the two major parties, but between 1914 and 1965 the Democrats never gained control of the senate and only five times had control of the house. In presidential elections since 1900 the state voted Democratic in 1912 (Woodrow Wilson), 1932, 1936 and 1940 (F. D. Roosevelt), 1960 (J. F. Kennedy) and 1964 (L. B. Johnson).

An intensely industrial state, New Jersey produced great quantities of war matériel during World War II. Important embarkation points for soldiers going to the European theatre of war were at Fort Dix and Camp Kilmer. The U.S. signal corps had its headquarters during the war at Fort Monmouth.

A constitutional convention, delegates to which had been popularly elected in 1947, assembled in New Brunswick and prepared a new constitution which the voters approved and which on Jan. 1, 1948, replaced the 103-year-old constitution. For the first time in more than 100 years the electorate beginning in Nov. 1949 could re-elect a governor and for the first time in 40 years the Republicans held the governorship for two successive terms. Legislative sessions in 1948–51 enacted the basic measures for effecting the structural changes required under the new constitution.

New Jersey had the lowest per capita state taxes of any state in the union at mid-20th century. In the decade between 1950 and 1960, construction, both industrial and residential, boomed. Gov. Robert B. Meyner became the first Democratic governor to succeed himself when he was re-elected in 1957.

GOVERNMENT

After New Jersey joined with the other Colonies in 1776 in declaring its independence, it set up a new form of government that established almost absolute legislative supremacy. This in a modified form was continued in the second constitution of 1844 and lasted till pressures generated by dynamic changes in 1947 forced the adoption of a third constitution.

Executive.—The 1947 constitution created a powerful governor, elected at large by the people, who serves a four-year term and is eligible for immediate re-election once and may serve additional terms after a lapse of one administration. The governor appoints all the state's executive officers, all the judicial officers whose jurisdictions extend farther than one community, the county prosecutors (district attorneys) and certain other county officials. The governor also prepares the annual budget, and may call special sessions of the legislature at will or of the senate separately. He has the right to veto acts of the legislature and specific terms in appropriation bills but only within 10 days of their submission to him while the legislature is in session or within 45 days after it adjourns sine die. He is empowered to supersede a county prosecutor as well as specifically order local police to move against specific offenses or offenders, and he has full powers of investigation concerning state and local administration. He is commander

in chief of the state's national guard and chairman ex officio of the state board of canvassers, which certifies all elections. Finally, he is empowered to make temporary appointments to the U.S. senate. In the event of his death, resignation or removal from office, he is succeeded by the president of the senate.

The constitution requires that all state administrative units be organized into not more than 20 departments whose heads are appointed by the governor and who serve at his pleasure. The only exceptions are the attorney general and the secretary of state, whose terms must coincide with that of the governor.

Legislature.—The state has a bicameral legislature composed of a general assembly and a senate. The general assembly comprises 60 members apportioned among the counties every ten years on the basis of population, although each county has at least one seat in the chamber. Senate membership of 21, one from each county, was increased in 1965 to 29, apportioned by population. Terms of office are two years for assemblymen and four for senators, with half the senators elected every two years.

The once extensive powers of the legislature were considerably reduced by the 1947 constitution. Under that constitution, the legislature enacts all state laws; adopts, approves or revises the state budget; enacts all appropriation bills; fixes all taxes; appoints the state auditor; may remove any executive or judicial officer by the impeachment process; and may override a governor's veto by a two-thirds majority of both houses. The senate, acting alone, confirms or rejects the executive and judicial appointments of the governor.

The legislature meets annually, usually from January until late spring, and then reassembles 45 days after its adjournment for a "veto session"; *i.e.*, to consider all bills the governor has vetoed.

Judiciary.—The New Jersey court system has been hailed by judiciary experts as the best and most flexible in the United States. At the head of the system is the supreme court, composed of a powerful chief justice and six associate justices. The supreme court is the final court of appeal in New Jersey and must finally decide all constitutional questions. Its members are appointed by the governor for an initial seven-year probationary term, after which they may be reappointed on a permanent basis, during their good behaviour, until the compulsory retirement age of 70.

Immediately below the supreme court is the superior court, composed of three divisions: law, appeals and chancery. The law division hears civil and criminal cases; the chancery division equity cases; the appeals division hears appeals from the law and chancery divisions and also from the lower courts. The qualifications, method of appointment and reappointment and terms for justice of the superior court are the same as those for the supreme court.

The lesser courts in the state are the county courts and the district courts, the judges of which are appointed by the governor; municipal courts appointed by local mayors; and the county surrogates are elected at large in each county. The county courts handle all types of cases and review the actions of the district and municipal courts. The district courts, covering only parts of counties, handle only those civil cases in which the amount of damages claimed is less than $3,000 or the crime is a misdemeanor. The municipal courts judge motor vehicle code violations and other lesser offenses.

Local Government.—County government in New Jersey is a hybrid of past and present customs of government in that it is composed of the old and large board of chosen freeholders (37 in Atlantic county, for example) in some areas and small boards (as few as 3) in others. The freeholders nominally operate and direct county government, but as many officials are either elected at large or appointed by the state the freeholders control little more than the county welfare institutions and some lesser clerical functions.

Since the 1947 constitution was adopted, municipal home rule has been the practice in New Jersey, whose more than 500 communities choose between 16 different combinations of the mayor-council, mayor-commission or council-manager types of municipal government. The most prevalent type is the mayor-commission form first advocated by Gov. Woodrow Wilson in 1911.

Finance and Taxation.—In the second half of the 20th century, the state's general treasury fund receipts amounted to more than $700,000,000 annually. Of this sum, about 10% was derived from the federal government and about 50% from state tax sources. Motor fuels, motor vehicle and operators licences, tobacco products, alcoholic beverages and property were the chief sources of tax revenues. The state's annual disbursements totaled slightly more than the general fund receipts and the state had a bonded debt of a little more than $200,000,000. Approximately 29% of the state's revenues was being spent on highways, about 26% on education, slightly more than 10% on health and hospitals and about 8% on public welfare. The state's income in the 1950s and 1960s was more than four times as great as it had been prior to World War II, but expenditures had multiplied at an even greater pace. New Jersey's per capita income had long been among the highest in the nation, and in 1960 it was about $2,200, well above the national average.

POPULATION

The population of New Jersey in the first federal census, 1790, was 184,139. This made it ninth among the 18 states and territories that then composed the union, and the population was classified as 100% rural. In 1850 the population of the state was 489,555, making it 19th in size among a total of 37; the state was still classified as rural in character—82.4% of its inhabitants were considered nonurban dwellers. The next decade was the period of the most rapid growth in the state's history—the population increased 37.3% between 1850 and 1860. At the beginning of the 20th century the state had advanced to 16th in rank of population with a total of 1,883,669 persons according to the 1900 census. The complexion of the state had been completely altered since 1850—in 1900 New Jersey was classified as 70.6% urban in character. The economically depressed decade between 1930 and 1940 was the slowest in population growth in New Jersey—in 1940 the population was only 2.9% greater than it had been in 1930. The 1950 population showed a total of 4,835,329 persons living within the state, making New Jersey eighth in size of population among the states. It was then nearly 87% urban in classification. In 1950 there were two complete standard metropolitan areas (Atlantic City and Trenton) and Bergen, Essex, Hudson, Middlesex, Morris, Passaic, Somerset and Union counties were a part of the New York-Northeastern New Jersey standard metropolitan area; they contained nearly three-fourths of the total population. By 1960 the standard metropolitan statistical areas housed 78.9% of the total population. In 1960 New Jersey had a total population of 6,066,782, an increase of 1,231,453 or 25.5% over 1950. It ranked eighth among the states.

The population per square mile in 1960, highest of the states, was 774.2, as compared with 49.6 for the U.S. as a whole. The 1960 urban population was 5,359,035 or 88.3% of the total. Distribution by colour and nativity, according to the 1960 census, was as follows: 81.3% native white; 10.0% foreign-born white; and 8.7% nonwhite. In line with the rest of the U.S. the percentage of persons 65 years old or over was increasing, being 9.1% in 1960. The percentage of the population 14 years old and over that was in the labour force was steadily decreasing, the result of prolonged schooling for that age group.

The population is not uniformly distributed across the state, but is concentrated in the urban belts opposite New York city and Philadelphia, with greater concentration opposite New York. Two-thirds of the population of the state live within 30 air miles of that city. Population density runs from an average of 40,000 persons per square mile in the industrial cities in the northeastern part of the state to sections of the state that have no people at all—in fact, almost one-fourth of the whole state's area is free of human habitation.

The over-all complexion of the state's population has changed slowly so that in 1960 New Jersey families tended to be older on the average and have fewer children than those of several decades previously. Also, the number of women increased more rapidly than that of men.

The basic characteristics of New Jersey's population tend to differ somewhat from the general national tendencies in regard to race, religion and degrees of concentration. In New Jersey there

*Populations are reported as constituted at date of each census. †Urban town (township). ‡Reported through 1950 as Raritan. §Name changed in 1945 from Chester. ‖Reported until 1940 as South Orange. ¶In Bergen county, name changed from Riverside in 1930. δReported until 1920 as Midland. ♀Reported until 1920 as Franklin.
Note Dash indicates place did not exist during reported census, or data not available.

are more Protestants than Roman Catholics, although the ratios are closer than in the nation as a whole. Likewise, New Jersey is one of the 11 major areas in the United States in which the nation's Jewish population is concentrated. There is a reversal in the state of the traditional trend of Negroes and foreign born to concentrate in industrial cities and towns. Agricultural southern New Jersey proportionately has more Negroes than does industrial northern New Jersey, and the coastal portions of the state have proportionately almost as many foreign born as do the industrialized areas. In some sections of the southern part of the state Negroes constitute a virtual majority of the residents. Roman Catholicism tends to be the major religious affiliation of the people in the industrialized cities and towns, while Protestantism usually predominates in the suburban, residential and agricultural portions of the state.

In the northeastern part of New Jersey the populace is largely comprised of persons who were born elsewhere than in New Jersey, but the number of nonnative-born diminishes sharply toward the south and west. In the farm areas of the state the people are almost entirely native born.

EDUCATION

History and Administration.—Public education in New Jersey progressed steadily throughout the 19th and 20th centuries. Early in the state's history the legislature gave consideration to funds for public schools, and in 1846 the post of state superintendent of public schools was established. The state constitution was amended in 1867 to require that "the Legislature shall provide for the maintenance of free public schools for the instruction of all children in the State between the ages of 5 and 18" with the result that a compulsory education law was enacted in 1867. Later, industrial and vocational schools were established, and special facilities were made available for crippled, blind, deaf and subnormal children.

Administration of the New Jersey schools is delegated to a state board of education and a commissioner of education appointed by the governor. A county superintendent of schools, appointed by the state board of education upon the recommendation of the state commissioner of education, has supervision over the public schools in each of the 21 counties. However, each city has a superintendent who exercises authority over the schools in the local area. Each municipality is theoretically also a school district, though efforts to provide better facilities have caused some municipal boards to merge and form combined districts.

There are two basic types of school boards in the state, one primarily designed for cities and the other for small municipalities. In the cities the mayor appoints the members of the board. In the small municipalities voters elect the members. The boards direct the finances and general policies of the school districts, select teachers, administrative personnel and materials and prescribe the curriculum. The boards also may expel pupils. The budgets of city boards are approved by a board of school estimates composed of members of the school board and the municipal council; in small municipalities the budget is adopted by voter action in a special election. In the 1960s, New Jersey was spending more than $500 annually per pupil—far above the national average.

Universities and Colleges.—Higher education has its roots in the colonial period. Princeton university, one of the nation's finest liberal arts universities for men, was established as the College of New Jersey at Princeton in 1746 (*see* PRINCETON UNIVERSITY). Rutgers, the state university, was founded as Queens college at New Brunswick in 1766; in 1825 its name was changed to Rutgers college in honour of Col. Henry Rutgers. The New Jersey legislature in 1864 selected the Rutgers Scientific school to be the land-grant college of the state. In 1880 the legislature established the New Jersey agricultural experiment station which was located on the Rutgers college farm. In 1917 Rutgers became the state university; in 1945 the title was extended to all its divisions. The corporate name was changed to Rutgers–the State university, in 1956. Rutgers now comprises these major units in New Brunswick: the college of arts and sciences, including the school of chemistry and the school of journalism; the college of engineering; the college of agriculture; the graduate school of education; Douglass college (founded as the New Jersey College for Women); the graduate school of library service; the graduate school of social work; and the graduate school of arts and sciences. In Newark are the college of pharmacy; the Newark college of arts and sciences; the school of business; the college of nursing; and the school of law. In Camden are the College of South Jersey and the South Jersey division of the school of law. Included in the university are the state agricultural experiment station, the Eagleton Institute of Politics, the Urban Studies centre and the Rutgers University press.

In 1855 the first New Jersey state normal school (now Trenton State college) was established by an act of the legislature at Trenton. Other teachers colleges are at Glassboro (1923), Jersey City (1946), Upper Montclair (1908), Union (1855) and Paterson (1855). In 1958 the six were designated as state colleges but continued to train teachers for the elementary and secondary schools.

Among the other institutions of higher learning are Seton Hall university at South Orange, Newark, Jersey City and Paterson (Roman Catholic; 1856); Fairleigh Dickinson university at Rutherford, Teaneck and Madison (nonsectarian; 1941); Drew university at Madison (Methodist; 1867); Stevens Institute of Technology at Hoboken (nonsectarian; 1870); Newark College of Engineering at Newark (state and municipal control; 1881); Caldwell College for Women at Caldwell (Roman Catholic; 1939); College of St. Elizabeth at Convent Station (Roman Catholic; 1899); Georgian Court college at Lakewood (Roman Catholic; 1908); Monmouth college at West Long Branch (nonsectarian; 1933); Rider college at Trenton (nonsectarian; 1865); St. Peter's college at Jersey City (Roman Catholic; 1872); Bloomfield college at Bloomfield (Presbyterian; 1868); and Upsala college at East Orange (Lutheran; 1893).

HEALTH, WELFARE AND CORRECTIONS

The state department of health is an outgrowth of a sanitary commission set up in 1865 and converted into a board of health in 1877. In 1954 the board became an eight-member public health council, two of whose members must be physicians and another a dentist. The council members, who are appointed by the governor, serve without pay. The council is charged with establishing and enforcing the state sanitary code as well as fixing the qualifications for health and food inspectors. Local health boards may establish higher, but not lower, standards than the state code by local ordinance and with the state's permission.

The state officially approves fluoridation of municipal water supplies, though less than 10% of the communities in the state had done so by 1960. About one-fifth of the state's communities have full- or part-time health officers, but only 13 counties have such an official. A special health problem in New Jersey is that of mosquito control. Fifteen counties maintain extermination commissions.

Public welfare activities in New Jersey are handled by the state department of institutions and agencies or the county boards of chosen freeholders. The state licenses and inspects all hospitals, nursing homes and sanatoria in addition to operating institutions for the insane, mentally deficient, feeble-minded and tubercular. Further, the state maintains diagnostic centres for juvenile and sex offenders and homes for aged public servants and veterans.

The state commission for the blind administers the education of the visually handicapped and assists them financially when necessary. The state board of child welfare cares for neglected and dependent children; the bureau of assistance aids the aged, disabled and indigent.

County governments and often the larger municipal governments aid in the welfare work of the state. Most counties and municipalities support or maintain general hospitals. Several counties of northern New Jersey have special hospitals or asylums for the treatment of chronic illnesses or mental disorders and clinics and welfare stations for the treatment of alcoholism and for child-care and other welfare problems. The counties and the municipalities augment the state's welfare payments to the aged, disabled and destitute.

The state has reformatories near Clinton and at Annandale and Bordentown; reform schools near Jamesburg and at Trenton; a state prison at Trenton and prison farms at Rahway and Leesburg.

THE ECONOMY

Living Conditions.—Living conditions generally are good in New Jersey, though in some northern areas where the population concentration is greatest housing tends to be inadequate and in some places substandard conditions prevail. In the second half of the 20th century urban renewal projects and new local housing and sanitation standards ordinances were rapidly eliminating the substandard areas. Newark, the largest city in the state, located in wholly urban Essex county, proportionately has had more federal housing aid than any other city in the United States (*see* NEWARK). Vast housing developments sprang up in the northeastern counties of the state as the move to suburbs extended outward from New York city into northern New Jersey. Extensive housing developments exist also all along the Delaware river and bay shore lines southward from Trenton to Gloucester City below Camden.

Industry.—Aside from the thousands of persons who work in the urban areas of New York city and Philadelphia, the state's people are engaged in those activities common to a major industrial state. During the second half of the 20th century more than 35% of the state's workers were employed by more than 12,000 different manufacturing concerns. Of the remaining labour force, about 17% were engaged in trade, 18% in services, 6% in construction activities, 3% in transportation operations, 5% in finance and insurance services, 3% in the communications industries and utilities, with the balance divided among all the other classifications except farming.

Industries have concentrated in New Jersey because of its proximity to major markets, easy access to transport facilities and a generally favourable tax climate. The state is well located for servicing a market consisting of more than 12 states, and it is within overnight hauling distance of 30% of the national population. The average weekly wage of a New Jersey resident employed in manufacturing is among the highest in the U.S.

The greater part of the important chemical industry is located in Middlesex, Union and Essex counties; auto and aircraft production are mainly in Bergen county; the electrical supplies industry is in Essex and Hudson counties, and shipbuilding is exclusive to Hudson and Camden counties. Transportation, fabricating, machine, ferrous metal and clothing industries are also of great importance. In the latter half of the 20th century, the factories of the state produced nearly $5,000,000,000 worth of finished goods annually. After World War II, many industrial research centres were established in New Jersey.

Agriculture.—The farms of the state include about 1,500,000 ac. of land of varying fertility which is concentrated on producing cash crops, chiefly products that may be readily canned or frozen, for the nearby metropolitan centres. In a typical year, the total value of the state's crops exceeds $150,000,000, with a crop volume measured in hundreds of thousands of tons. Principal crops are sweet corn, peppers, tomatoes, asparagus, beets, beans, melons and potatoes. In addition, the state produces large quantities of berries of all kinds, grapes, apples (nearly 4,000,000 bu. a year) and peaches (nearly 2,500,000 bu. a year). Livestock and livestock products are also important to the agricultural economy. Eggs, a major agricultural product, exceed 2,500,000,000 annually. Milk production is more than 1,000,000,000 lb. yearly. Meat production is less spectacular, though chickens and broilers are of major importance.

Fisheries.—The commercial aspects of fishing are largely confined to clam digging and hard- and soft-shell mussel trawling off the marshes of the three southernmost counties fronting on Delaware bay. Otherwise, most of the rest of the fishing done is of a sporting nature and is classified as part of the vacation industry.

Mining.—New Jersey is rich in a few mineral resources. Its zinc deposits are among the finest in the world, assaying at more than 20% pure ore; the Ogdensberg zinc mines in Sussex county are especially famous for their richness. Other minerals found in the state are iron ore, building materials, lime, greensand marl, peat and semiprecious stones. Iron has been mined in New Jersey for nearly 300 years, and great quantities of magnetite ore are found throughout the northern two-thirds of the state; the industry declined after the Civil War, and only a few mines were in operation in the second half of the 20th century. Building materials minerals are the most developed and are commercially the most significant minerals. Annual quantities of clay produced for brick, tile and terra-cotta ware total many millions of tons, as does stone, sand, gravel and lime production. The average annual value of all mineral products produced in New Jersey is a little less than $100,000,000, which, compared with other phases of the state's economy, makes mining a small operation.

Resorts.—Another important New Jersey industry is vacation recreation. Aside from the smaller (but often year-round) vacation industries found along the state's more than 700 lakes, the vacation industry principally is spread in an ever-widening belt along the Atlantic coast line from the Atlantic Highlands off lower Hudson river bay southward to Cape May, with principal concentrations in Ocean and Atlantic counties. There, several cities and many towns offer fine, wide, safe, sandy beaches and cool, moderate surf in which to swim, boat or fish. This "New Jersey Riviera" has its finest facilities at Atlantic City (*q.v.*), a year-round resort centre with eight miles of boardwalks, large amusement piers and a large convention hall. Off these resorts are some of the finest sport fishing grounds in the world, especially for bluefish, weakfish, bonita, tuna, marlin and striped bass.

Transportation and Communication.—Its many transportation facilities and its geographical location helped make New Jersey a crossroads of the eastern section of the nation. The network of railroads number 23, including eight trunk lines; the trackage per square mile exceeds that of any other state. Eight freight terminals handle cargo bound for all parts of the world.

The state is favourably located for shipping near the port of New York (*see* also PORT) and with its own port facilities along the Delaware river. Port Newark handles export and import tonnage of major economic significance. There are ports also at Camden and Trenton.

There are approximately 30,000 mi. of modern highways and roads in the state, which pioneered in building the clover-leaf circle, the dual highway and the elevated highway. The two principal highways in the state system are the New Jersey turnpike and the Garden State parkway. The turnpike, operated by the New Jersey Turnpike authority, is a 131-mi. toll road extending from the George Washington bridge in the north to the Delaware Memorial bridge to the south and with a spur to the Holland tunnel and a link to the Pennsylvania turnpike. The parkway, also a toll road, is 173 mi. in length and is operated under the direction of the New Jersey Highway authority. It extends from the New York state line in the north to Cape May in the south.

There are approximately 100 commercial airports and private landing fields in the state. Newark and Teterboro, operating as passenger and air freight terminals, are the largest.

Both television and radio experiments have been conducted in the laboratories of the state. Stations WJZ (later WCBS) and WOR, initially in Newark, were pioneers in the field of radio. Research in television has been done by the Radio Corporation of America research laboratory in Princeton and the Allen B. Dumont laboratory in Clifton. There are more than 250 newspapers in the state, of which about 25 are daily.

BIBLIOGRAPHY.—*Geography:* For fuller descriptions consult the United States Geological Survey, *Bulletins 177* and *301* as well as the *Final Report* of the New Jersey Geological Survey and the *Annual Reports* of the New Jersey State Museum. For a listing of the state parks consult Fitzgerald's *Legislative Manual* (annual) and the individual publications of the parks themselves or the general pamphlet materials obtainable from the state Department of Conservation. *History:* For further historical details *see* the *Outline History of New Jersey* (1950) by the New Jersey History Committee; E. J. Fisher, *New Jersey as a Royal Province, 1738 1776* (1911); E. P. Panner, *The Province of New Jersey, 1664–1738* (1908); W. E. Sackett, *Modern Battles of Trenton* (1895); and the *New Jersey Archives* by the New Jersey Historical Association for specific areas or periods. *Government:* For a thorough

study of New Jersey government consult Bennett M. Rich, *The Government and Administration of New Jersey* (1957), which contains a thorough bibliography for the detailed aspects of specific phases of state government, as well as Fitzgerald's *Legislative Manual* (annual) for administrative details. Other useful sources are the *Reports* of state commissions and agencies. *Education:* The *Report* of the Commission to Survey Public Education (1928) is useful as are the *Annual Reports* of the state Department of Education and the somewhat more recent state Board of Education study on *Opportunities for Higher Education in New Jersey* (1958). *Health and Welfare:* The best sources are the special reports of the Department of Institutions and Agencies dealing with *Public Health Resources in New Jersey* (1947); the *Report on Mental Deficiency in New Jersey* (1954) by a select commission to study the problem, while Paul T. Stafford generally covers public assistance in his work *Government and the Needy* (1941). *Economy:* The *Reports* of the Department of Conservation and Development generally give the most accurate and current picture of the state's economy as do the *Reports* and *Studies* of the state Tax Commission. General works such as those by the Department of Economics and Social Institutions of Princeton University may be very helpful as also might the *Reports* of the state Department of Agriculture, the Commission on Water Supply, the Utilities Commission, the Turnpike Authority, and the publication *New Jersey Business* by the state Department of Conservation and Economic Development in conjunction with the Rutgers School of Business Administration.

Other useful books on New Jersey are the Federal Writers' Project book *New Jersey* (1939), the state's Department of Public Instruction study, *New Jersey, Its History, Resources and Life* (1940), and John T. Cunningham, *This is New Jersey* (1953), among many others. There are numerous specialized works on special areas of the state listed in many of the above.

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures are summarized annually in the *Britannica Book of the Year*, American edition. (D. N. A.; M. P. M.)

NEW JERSEY TEA (*Ceanothus americanus*), a North American shrub of the buckthorn family (Rhamnaceae), called also Indian or Walpole tea and redroot, native to dry open woods and gravelly banks from Manitoba southward to Florida and Texas. Its low, branching stems, one to three feet high, which spring from a dark red root, bear ovate, three-ribbed, somewhat downy, toothed leaves and attractive white flowers in umbellike clusters. During the American Revolutionary War the leaves were used as tea. *See* also CEANOTHUS.

NEW KENSINGTON, a city of Westmoreland county in western Pennsylvania, U.S., about 18 mi. N.E. of Pittsburgh, is located on the Allegheny river.

Situated in the centre of a coal-mining district, the city has been a leading producer of aluminum since 1892 and is one of the earliest homes of that industry. Manufactures include, besides aluminum products, tubing, conduits, steel castings, water heaters, glass and textiles.

New Kensington was laid out in 1891 on the site of Ft. Crawford of the American Revolutionary period by a group of Pittsburgh capitalists interested in the reduction of aluminum. Incorporated as a borough in 1892, it absorbed neighbouring Parnassus in 1931 and became a city in 1933. For comparative population figures *see* table in PENNSYLVANIA: *Population.* (M. R. Wo.)

NEWLANDS, JOHN ALEXANDER REINA (1838–1898), English chemist whose law of octaves anticipated later discoveries concerning the periodic law (*q.v.*), was born in Southwark in 1838. He studied under August W. von Hofmann in the Royal College of Chemistry, London. Of Italian extraction on his mother's side, he fought as a volunteer in the cause of Italian freedom under Giuseppe Garibaldi in 1860. Later he was employed as an industrial chemist.

Newlands was one of the first to propound the conception of periodicity among the chemical elements, his earliest contribution to the question taking the form of a letter published in the *Chemical News* in Feb. 1863. In the succeeding year he showed, in the same journal, that if the elements be arranged in the order of their atomic weights, those having consecutive numbers frequently either belong to the same group or occupy similar positions in different groups, and he pointed out that each eighth element starting from a given one is in this arrangement a kind of repetition of the first, like the eighth note of an octave in music. The law of octaves thus enunciated was at first ignored or treated with ridicule as a fantastic notion unworthy of serious consideration, but the idea, subsequently elaborated by D. I. Mendeléyev (*q.v.*) and other investigators of the periodic law, took its place as an important generalization in modern chemical theory. Newlands collected his various papers on the elements in a little volume entitled *Discovery of the Periodic Law* (1884). He was awarded the Davy medal of the Royal society in 1887. He died in London on July 29, 1898.

NEW LAWS, rules for the government of Spain's American colonies, were promulgated by Charles I of Spain on Nov. 20, 1542, to remedy problems resulting from imperial expansion and from continued abuse of the Indians. Purportedly inspired by Father Bartolomé de Las Casas, these laws provided for: (1) an administrative reorganization of the American colonies; (2) checking an incipient feudalism; and (3) more humane treatment for the Indians. One series of clauses dealt with administrative divisions and the operation of the courts and bureaucracy. Feudalism was to be controlled by reducing the powers of the Spanish overlords in regard to their encomiendas, the system by which they collected tribute from specified Indian villages in return for protecting and Christianizing them. Encomiendas were to be examined for possible reductions in size, some were to be abolished, no new ones were to be granted and they could no longer be inherited. The laws provided for more humane treatment of the Indians by forbidding their enslavement and branding; releasing slaves held under defective titles; abolishing compulsory Indian service; controlling the working conditions of porters and pearl divers; granting Indians special privileges in the law courts; freeing the remaining Indians of the West Indies from tribute payments and making them legally equal to Spaniards; and, finally, enlarging the powers of royal officials in supervising Indian affairs and in collecting tribute for the crown.

The New laws proved unenforceable. Spaniards in Peru revolted and beheaded the viceroy. In Mexico the laws were not even proclaimed. Petitions of protest flooded Spain. In 1545 and 1546 the more unpopular sections of the laws were revoked, particularly those that affected existing encomiendas. Despite this initial setback, continued pressure was maintained by the crown until the encomienda disappeared in the 18th century. (M. D. Br.)

NEW LONDON, a city and port of entry in southeastern Connecticut, U.S., about 50 mi. E. of New Haven, is situated on Long Island sound at the mouth of the Thames river. Originally called Nameaug by the Indians and Pequot by white settlers when founded by John Winthrop the Younger in 1646, its name was changed to New London in 1658. In 1709 the first printing press in Connecticut was established there. During the American Revolution New London's privateers irritated British commanders so much they dispatched a landing force under Benedict Arnold which set fire to the city and nearly wiped it out on Sept. 6, 1781. Soon rebuilt, it was incorporated as a city in 1784. New London has one of the deepest harbours on the Atlantic coast and its early history was decisively influenced by the sea. During the 19th century it was a leading whaling and sealing port and, before being blockaded during the War of 1812, had a large trade with the West Indies and the Mediterranean. In the 20th century the New London area became the site of a U.S. navy submarine base with its school for submariners and underwater sound laboratory. Major industries include shipbuilding and the manufacture of clothing, pharmaceuticals, printing presses, engines, paper products, furniture and metal fabrications. Among the educational facilities of New London are Connecticut college (1911) for women, the U.S. Coast Guard academy (1876) and Mitchell (junior) college (1938). Notable buildings include old Fort Trumbull at the harbour entrance, the old town mill (1650), Hempstead house (1678), the Huguenot house (1759), the county courthouse (1784) and the New London lighthouse (1760). The annual Yale-Harvard boat races are held on the Thames in June. Pop. (1960) 34,182; New London-Groton-Norwich standard metropolitan statistical area (New London and Norwich cities and East Lyme, Groton, Ledyard, Montville, Preston, Stonington and Waterford towns), 156,913. Griswold, Lisbon, Old Lyme and Sprague towns, pop. (1960) 14,068, were added in 1963. For comparative population figures *see* table in CONNECTICUT: *Population.* (W. D. Lo.)

NEW MADRID, a small town on the right bank of the Mississippi river is the seat of New Madrid county, Mo. It originated as an Indian trading post about 1783. In 1789 Col. George Morgan of New Jersey received a large land grant from the Spanish minister to the U.S. as part of a plan to attach western settlers to the Spanish province of Louisiana; hence the name. He laid out an elaborate townsite extending for four miles along the river; it has several times been relocated because of floods and changes in the course of the river. The town grew rapidly in farming and trade after the purchase of the Louisiana territory by the U.S. in 1803, but was set back by a series of severe earthquakes in 1811–12.

The city played a minor role in the American Civil War in 1862. When the loss of Forts Henry and Donelson made their base at Columbus, Ky., untenable, the Confederates withdrew downriver 60 mi. to Island No. 10, a heavily fortified position of great natural strength at a sharp bend in the river. New Madrid, seven miles farther down the river on a reverse bend, was also occupied. The Federals immediately pushed downriver, employing the amphibious tactics that were proving so effective on western waters. Maj. Gen. John Pope worked his way southward through the Missouri swamps with an army of 20,000 while Commodore A. H. Foote headed downstream with his flotilla of ironclads, wooden gunboats, transports and barges. Pope outflanked New Madrid by occupying Point Pleasant eight miles below, and when the Confederates withdrew across the river to safety, he occupied the post. But he could not move farther so long as the Confederates controlled the river below Island No. 10. When naval bombardment failed to reduce the defenses at the Island stronghold, two ironclads, the "Carondelet" and the "Pittsburgh," ran the batteries on April 4 and 7. Meanwhile, the army cut a shallow canal across the peninsula in front of the island and enabled light draft transports and supply barges to avoid the heavy guns and bring supplies and support to Pope. The Confederates, trapped between Federal forces and unable to escape into Tennessee because of the high water in the swamps, had no choice but to surrender.

(C. W. Te.)

NEWMAN, JOHN HENRY (1801–1890), Tractarian leader in the Church of England and then one of the most influential Roman Catholic converts of the 19th century, was born in London on Feb. 21, 1801. After an education in an evangelical home and at Trinity college, Oxford, he was made a fellow of Oriel college, Oxford, in 1822; vice-principal of Alban hall in 1825; and vicar of St. Mary's, Oxford, in 1828. Under the influence of John Keble and Richard Hurrell Froude (*qq.v.*) he became a convinced high churchman. When the Oxford movement (*q.v.*) began he was its effective organizer and intellectual leader, supplying the most acute thought produced by that movement. His editing of the *Tracts for the Times* and his contributing of 24 tracts among them were less significant for the influence of the movement than his books, especially the *Lectures on the Prophetical Office of the Church* (1837), the classic statement of the Tractarian doctrine of authority; the *University Sermons* (1843), similarly classical for the theory of religious beliefs; and above all his *Parochial and Plain Sermons* (1834–42), which in their published form took the principles of the movement, in their best expression, into the country at large. In 1838 and 1839 Newman was beginning to exercise far-reaching influence in the Church of England, because the stress upon the dogmatic authority of the church was felt to be a much-needed reemphasis in a new liberal age; because he seemed so decisively to know what he stood for and where he was going; because in the quality of his personal devotion his followers found a man who practised what he preached; and because he had been endowed with the gift of writing sensitive and sometimes magical prose.

Newman was contending that the Church of England represented true catholicity and that the test of this catholicity (as against Rome upon the one side and what he termed "the popular Protestants" upon the other) lay in the teaching of the ancient and undivided church of the Fathers. From 1834 onward this *via media* was beginning to be attacked on the ground that it undervalued the Reformation; and when in 1838–39 Newman and Keble edited and published Froude's *Remains*, in which the Reformation was violently denounced, moderate men began to suspect their leader. Their worst fears were confirmed in 1841 by Newman's *Tract 90*, which, in reconciling the Thirty-Nine Articles with the teaching of the ancient and undivided church, appeared to some to assert that the articles were not incompatible with the doctrines of the Council of Trent; and Newman's extreme disciple, W. G. Ward (*q.v.*), claimed that this was indeed the consequence. Bishop Richard Bagot of Oxford requested that the tracts be suspended; and in the distress of the consequent denunciations Newman increasingly withdrew into isolation, his confidence in himself shattered and his belief in the catholicity of the English church weakening. He moved out of Oxford to his chapelry of Littlemore, where he gathered a few intimate disciples and established a quasi monastery. He resigned St. Mary's Oxford on Sept. 18, 1843, and preached his last Anglican sermon ("The Parting of Friends") in Littlemore church a week later. He delayed long, because his intellectual integrity found an obstacle in the historical contrast between the early church and the modern Roman Catholic Church; but meditating upon the idea of development, a word then much discussed in connection with biological evolution, he applied the law of historical development to the Christian society and tried to show (to himself as much as to others) that the early and undivided church had developed rightly into the modern Roman Catholic Church, and that the Protestant churches represented a break in this development, both in doctrine and in devotion. These meditations removed the obstacle and on Oct. 9, 1845, he was received at Littlemore into the Roman Catholic Church, publishing a few weeks later his *Essay on the Development of Christian Doctrine*.

Newman went to Rome to be ordained to the priesthood and after some uncertainties founded the Oratory at Birmingham in 1848. He was suspect to the more rigorous among Roman Catholic clergy because of the quasi-liberal spirit which he seemed to have brought with him (his mode of expressing the idea of doctrinal development, his teaching on the nature of faith) and therefore, though in fact he was no liberal in any normal sense of the word, his early career as a Roman Catholic priest was marked by a series of frustrations, as he at least felt them to be. In 1852–53 he was convicted of libeling the immoral Italian priest Achilli. He was summoned to Ireland to be the first rector of the new Catholic university in Dublin, but the task was in the conditions impossible, and the only useful result was his lectures on the *Idea of a University* (1852). His part in the *Rambler*, and in the endeavour of Lord Acton (*q.v.*) to encourage critical scholarship among Catholics, rendered him further suspect and caused a breach with H. E. Manning, once himself a Tractarian and soon to be the new archbishop of Westminster. One of Newman's articles ("On Consulting the Faithful in Matters of Doctrine") was delated to Rome on suspicion of heresy. He attempted to found a Catholic hostel at Oxford and was thwarted by the opposition of Manning.

From the sense of frustration engendered by these experiences Newman was delivered in 1864 by an unwarranted attack from Charles Kingsley upon his moral teaching. Kingsley in effect challenged him to justify the honesty of his life as an Anglican. And though he treated Kingsley more hardly than was justified, the resulting history of his religious opinions, *Apologia pro vita sua* (1864), was read and approved far beyond the limits of the Roman Catholic Church; and by its fairness, candour, interest and the beauty of some passages recaptured that almost national status which he had once held. Though the *Apologia* was not liked by Manning and those who thought with him, because it seemed to show the quasi-liberal spirit which they feared, it assured Newman's stature in the Roman Catholic Church; and the new pope (Leo XIII) made him a cardinal (1879). Meanwhile he had expressed opposition to a definition of papal infallibility in 1870, though himself a believer in the doctrine, and had published his most important book of theology since 1845, *An Essay in Aid of a Grammar of Assent* (1870), which contains a further consideration

of the nature of faith and an attempt to show how faith can possess certainty when it rises out of evidence which can never be more than probable. He died at Birmingham on Aug. 11, 1890, and is buried (with his closest friend, Ambrose St. John) at Rednal, the rest house of the Oratory.

Newman's portraits show a face of sensitivity and aesthetic delicacy. He was a poet—most famous are his contributions in the *Lyra Apostolica* of his Anglican days, including the hymn "Lead, kindly light," written in 1832 when he was becalmed in the strait between Sardinia and Corsica, and *The Dream of Gerontius* (1865), based upon the requiem offices and including such well-known hymns as "Praise to the holiest in the height" and "Firmly I believe and truly"—and his thought as a philosopher or theologian was never far from the poetic apprehension. He was always conscious of the limitations of prose and aware of the necessity for parable and analogy, and logical theologians sometimes found him elusive or thought him muddled. But his was a mind of penetration and power, trained upon Aristotle, Hume, Bishop Joseph Butler and Richard Whately, and his superficial contempt for logic and dialectic blinded some readers into the error of thinking his mind illogical. His intellectual defect was rather that of over-subtlety; he enjoyed the niceties of argumentation, was inclined to be captivated by the twists of his own ingenuity, and had a habit of using the *reductio ad absurdum* in dangerous places. Newman's mind at its best is probably to be found in parts of the *Parochial and Plain Sermons* or the *University Sermons*, at its worst in the *Essay on Ecclesiastical Miracles* of 1843.

His sensitive nature, though it made him lovable to his few intimates, made him prickly and resentful of public criticism, and his distresses under the suspicions of his opponents, whether Anglicans defending the Reformation or ultramontanes attacking his Roman theology, weakened his confidence and prevented him from becoming the leader which he was otherwise so well equipped to be. Nevertheless as the effective creator of the Oxford movement he helped to transform the Church of England; and as the upholder of a theory of doctrinal development he helped Catholic theology to become more reconciled to the findings of the new critical scholarship, while in England the *Apologia* was important in helping to break down the cruder prejudices of Englishmen against Catholic priests. In both churches his influence has been momentous.

BIBLIOGRAPHY.—The most important works by Newman have been mentioned above. They have been reprinted, a few of them often, but as Newman was in the habit of making substantial alterations when re-editing, their text-history needs care: *see* J. Rickaby, *Index to the Works of John Henry Cardinal Newman* (1914).

Many of his letters as an Anglican were published by Anne Mozley, 2 vol., 2nd ed. (1898); his correspondence with Keble and others was edited from the Birmingham Oratory in 1917; his correspondence with William Froude by G. H. Harper in 1933. C. S. Dessain (ed.), *The Letters and Diaries of John Henry Newman*, vol. xi– (1961–) is definitive. For his life *see* the bibliography of the article OXFORD MOVEMENT; W. P. Ward, *The Life of John Henry, Cardinal Newman*, 2 vol., new ed. (1927); M. Trevor, *Newman*, 2 vol. (1962).

For his thought, *see* J. Guitton, *La philosophie de Newman* (1933); M. Nédoncelle, *La philosophie religieuse de John Henry Newman* (1946); S. P. Juergens, *Newman on the Psychology of Faith in the Individual* (1928); A. D. Culler, *The Imperial Intellect* (1955); O. Chadwick, *From Bossuet to Newman: the Idea of Doctrinal Development* (1957); J. H. Walgrave, *Newman: the Theologian* (1960).

(W. O. C.)

NEWMARKET, the "gateway to East Anglia," a market town and urban district of West Suffolk, Eng., 13 mi. E.N.E. of Cambridge by road. Pop. (1961) 11,207. Though the town is in West Suffolk, and Suffolk is its postal address, the rural district is in Cambridgeshire. Newmarket, on the main London to Norwich road, is the home of the Jockey club and has been celebrated for its horse races from the time of James I. Charles I instituted the first cup race there in 1634. Two of the five "classic" races are held there in the spring—namely, the Two Thousand Guineas (colts) and the One Thousand Guineas (fillies) both for three-year olds—and in the autumn two of the most popular handicap races, the Cesarewitch and the Cambridgeshire. Besides the breeding, training, racing and selling of racehorses, light industry in the form of caravan (trailer) manufacture and the making of electronic and magnetic devices has been established.

There are two racecourses on Newmarket heath, southwest of the town: the Rowley Mile course, used in the spring and autumn, and the July course, used in the summer. The Rowley Mile intersects the Devil's ditch or dike, an earthwork extending 7½ mi. from Wood Ditton to Reach, which is thought to have been built by the East Anglians as a defense against the Mercians about the 6th century A.D. and which later formed the boundary of East Anglia. The district contains chalk downland with its peculiar flora and fauna, and Wicken fen, a nature reserve belonging to the National trust.

(J. Cr.)

NEW MEXICO, the "Land of Enchantment" or "Sunshine state," one of the states of the United States, is located in the southwestern part of the country. Roughly rectangular in shape, it is bounded north by Colorado, east by Oklahoma and Texas, south by Texas and the republic of Mexico and west by Arizona. Its length north and south is 391 mi., its width east and west 344 mi.; the total area is 121,666 sq.mi. (of which only 156 sq.mi. are water surface), making it fifth in area among the states. New Mexico was admitted to the union in 1912 as the 47th state. The state flag is a field of yellow containing in its centre the ancient Zia sun symbol in red. The state flower is the yucca flower, the bird the road runner (*Geococcyx californianus*), the state song "O, Fair New Mexico." The capital is at Santa Fe (*q.v.*).

PHYSICAL GEOGRAPHY

Physical Features.—The borders of New Mexico (lat. 31° 20′ to 37° N.; long. 103° to 109° W.) are high plateaus cut by deep canyons; in the central part faulted mountains surround comparatively level areas formed of alluvial deposits. Between the Rio Grande and the Pecos valleys the mountains form a more continuous range than on the west side of the Rio Grande, where the elevated areas carry the continental divide.

The Sangre de Cristo mass, an extension of the Colorado mountains, lies slightly east of the north-central part of New Mexico east of the Rio Grande. South of this northern mass two series of ranges extend to the southern boundary: nearest the Rio Grande the Sandía, Manzano, San Andrés, Oscura and Organ mountains, farther east the Pedernal, White, Sacramento and Guadalupe mountains.

West of the Rio Grande the San Juan mountains dominate the country north of the Chama river; a somewhat smaller mass the Jemez mountains, lies between the Chama and the Jemez river. The Puerco river separates the Jemez mountains from the Mt Taylor mountains, which carry the main divide southwesterly to the Zuni mountains and on into one of the largest mountain masses in the state, with the Black range closest to the Rio Grande and the Mogollons, the San Mateo and the Magdalena as outlying ridges toward the west. In the extreme southwestern part of the state the mountains terminate in several parallel ridges: the Burro, Big Hatchet and Peloncillo mountains.

The major divides, following the tops of the ridges and the high plateaus, run generally north and south. The most important are the divides between the Pecos and the Canadian valleys; between the Pecos and Tularosa valleys; between the Tularosa and the Rio Grande; and between the Rio Grande and the San Juan, Little Colorado and Gila valleys.

The rivers are the only important bodies of water, but the Rio Grande and the Canadian have been dammed to form the Elephant Butte and Caballo reservoirs on the Rio Grande, and Conchas reservoir on the Canadian; primarily useful for irrigation, these reservoirs also offer fishing and water sports. The Cimarron, tributary to the Arkansas, and North Canadian rivers rise in the northeastern part of the state, in Union county. The Canadian, also tributary to the Arkansas, flows through Colfax, Mora, San Miguel and Quay counties, draining the eastern slope of the Sangre de Cristo range, the southern flank of which drains into the Pecos river; this in turn flows southward across the state.

The Rio Grande, the only important river that does not have its source in the state, enters New Mexico through a deep canyon just east of the 106th meridian and flows south through the centre of the state. On the western side of the continental divide the principal rivers are the San Juan, Little Colorado and Gila, tributaries

of the Colorado, which flows into the Gulf of California.

Climate.—The climate of New Mexico is generally sunny and relatively dry (average rainfall 14.3 in.) but with considerable variation depending on altitude. Extremes of temperature range from 110° to −29° F. Winter average temperature is about 39° in the south and 29° in the north; summer averages are about 77° and 68°, respectively. Prevailing summer winds blow from the southeast, bringing the summer rains from the Gulf of Mexico. Occasional winter winds from the northwest bring cold, especially to the northwest quarter of the state. Relative humidity is low; Albuquerque, in the centre of the state, has a winter minimum of 24% and a maximum of 58%.

Soil.—The soils of New Mexico generally contain a large amount of mineral matter and a small amount of organic matter; the alluvial soils are deep and very productive when irrigated.

Vegetation and Animal Life.—Altitude, determining climate, also largely determines the distribution of plants and animals. Six zones are recognized, ranging generally from southern valleys of less than 3,000 ft. above sea level to above the timber line, where only arctic lichens and grasses grow. The tallest peak, Wheeler peak in the Sangre de Cristo range above Taos, rises to 13,600 ft.

Lower Sonoran Zone.—The lowest zone, Lower Sonoran, is characterized by mesquite, creosote bush, yucca, desert willow, cottonwood, many varieties of cactus and Spanish bayonet. There are many species of mice, rats, squirrels, skunks and bats; also the coyote, the New Mexico desert fox and weasel and the Mexican badger. Birds include the scaled quail, Scott's oriole, the sparrow, the western mockingbird and the road runner. This zone covers about 18,000 sq.mi. of the state's most fertile land, which is very productive with irrigation.

Upper Sonoran Zone.—The zone above, the Upper Sonoran, from 3,000 to 7,500 ft. of altitude, is the largest, covering about 92,000 sq.mi., three-quarters of the state, and with irrigation is the most productive. Its natural growth consists of piñon and juniper trees and blue grama, galleta, buffalo and porcupine grasses, which make fine range for cattle. These wide grassy plains extend eastward into Texas as the Staked plains (Llano Estacado). Several species of deer, antelope, coyote, wolves and prairie dogs are common to the area; mountain sheep, which had almost disappeared, are coming back with protection.

Upper Zones.—The three zones above the Upper Sonoran—Transition, Canadian and Hudsonian—bear fine timber. Above 8,000 ft., ponderosa pine is replaced by several varieties of fir and spruce, all varied by scrub oak and quaking aspen which covers burned over areas with its delicate green in summer, its golden yellow in autumn. These forests offer good hunting of deer and, in some places, elk. Black and brown bears are found there, and mountain lions prey on smaller animals and domestic stock. In the Arctic-Alpine zone, above 12,000 ft., only a few grasses, lichens and alpine sedges grow.

Parks, Monuments and Recreation.—New Mexico possesses many attractions for tourists, among them the Carlsbad Caverns National park (*q.v.*), at Carlsbad. The state also embraces nine national monuments: Aztec ruins, at Aztec; Bandelier, near Santa Fe; Capulin mountain, near Raton; Chaco canyon, near Bloomfield; El Morro, at El Morro; Ft. Union, near Watrous; Gila cliff dwellings, near Silver City; Gran Quivira, at Gran Quivira; and White Sands, near Alamogordo. State parks are Hyde, at Santa Fe, Bottomless lakes, near Roswell; Conchas dam, Tucumcari; Kit Carson memorial, Taos; City of Rocks, near Deming; and Bluewater lake, near Grants. State monuments are Mesilla plaza, Mesilla; El Palacio, Santa Fe; Abo, near Mountainair; Pecos, Pecos; Coronado, near Bernalillo; Quarai, near Mountainair; Jemez, Jemez Springs; Lincoln, Lincoln.

HISTORY

Prehistory.—In New Mexico and other areas of the southwest the peripheries of at least two distinct prehistoric Indian cultures touched: the agrarian, docile early groups, and the later aggressive and nomadic Navaho and Apache. The Sandia cave and Folsom men represent the earliest evidences of human life discovered on the North American continent. For at least 10,000 years man has inhabited New Mexico. Pre-Pueblo Hohokam and Salado Indians were agriculturalists and irrigators. The Anasazi built cities. Among their more interesting ruins are those in the San Juan valley and Chaco canyon. Approximately 1,000 years ago came the Navaho and then the Apache.

Exploration.—Recorded history began between 1525 and 1543 when Spanish explorations extending from Florida to California paved the way for Spain's colonization of Florida and New Mexico in the 16th and 17th centuries, Texas and California in the 18th. The first explorer to cross the continent was Alvar Núñez Cabeza de Vaca, who, with three companions, reached the Gulf of California and went on to Mexico City, capital of the viceroyalty of New Spain. There his reports inspired Viceroy Antonio de Mendoza to undertake explorations to the north. He sent out an expedition headed by a Franciscan friar, Marcos de Niza, which reached the Zuñi pueblos in western New Mexico and brought back such dazzling (though untrue) reports of wealth (the myth of the Seven Golden Cities of Cibola) that in 1540 Francisco Coronado, with a well-equipped force of 300 soldiers, marched north over the same trail. Coronado proceeded to the Rio Grande and established winter quarters near Bernalillo. His lieutenants conquered the pueblos as far north as Taos and pushed as far west as the Grand canyon. Coronado himself reached mid-Kansas.

Coronado found no gold, but the friars converted many Pueblo Indians, who farmed small irrigated plots of land and were generally peaceful. His reports, circulated in Mexico, inspired missionaries, and in 1581 Augustín Rodríguez, a Franciscan friar, led an expedition into New Mexico. Rodríguez' military escort soon returned to Mexico, however, leaving the friars behind, and in 1582 Antonio de Espejo set out to rescue them. In this year the name New Mexico was applied to the Rio Grande pueblos, and it appeared in a contract made in 1595 with Juan de Oñate for the colonization of the area.

Colonization.—Oñate's expedition entered New Mexico at the pass (present El Paso) and proceeded up the Rio Grande to its confluence with the Chama river. There Oñate established San Juan de los Caballeros as his capital, and the first mass was said there on Sept. 9, 1598. Santa Fe, the present capital of New Mexico, was founded in 1610. To Oñate may be attributed the permanent settlement of the area. His conquest and settlement were described in Villagrá's *Historia del Nuevo Méjico*, an epic poem, the first poem written about any section of the U.S., published at Alcalá de Henares, Spain, in 1610.

New Mexico remained a frontier mission field until the 19th century. Twenty friars were serving there in 1624, there were 43 churches and Christian Indians were counted as 3,400. The total Spanish population was only 2,000, an indication that the colony had not become an important source of wealth. The friars, pressing hard to eradicate the Indians' traditional beliefs, aroused such opposition that in 1680 the Pueblos revolted, killed many Spanish settlers, including priests, and drove the rest south to El Paso.

In 1692 Spanish troops under Diego de Vargas re-entered New Mexico, occupied the whole province and by 1696 had peaceably re-established Spanish rule. Later the Spanish kings confirmed the Pueblos' ownership of their lands by royal grants which are the basis of their present holdings. During the 18th century colonists from Mexico continued to enter New Mexico and were granted lands as groups or as individuals. They founded such enduring towns as Socorro in the south, Don Fernando de Taos near Taos pueblo, Santa Cruz north of Santa Fe and others less important.

Albuquerque (*q.v.*), founded in 1706, became the centre of southern New Mexico, with a population of 4,020 by 1799. The total population of the province, which extended from Louisiana to California, was then about 30,000, including 20,000 Spanish and 10,000 peaceful Indians. Warlike Indians, especially Navaho, Apache and Comanche (*qq.v.*) nomads, harried Spanish towns and Indian pueblos alike. Spain offered the Indians, the towns and pueblos little protection, as the Spanish empire was breaking up.

Mexican Rule.—By 1823 the old viceroyalty of New Spain had attained its independence and had become the republic of Mexico. This change was little noted in New Mexico, which was

beginning to look eastward. The Mexican government had legalized trade with the Missouri valley towns, which had been discouraged by Spain, and in 1821 the first annual caravan left Missouri for Santa Fe (*see* SANTA FE TRAIL). Trade over the Santa Fe trail grew in value from $15,000 in 1822 to $450,000 in 1843.

The republic of Texas, established in 1836, claimed the Rio Grande as its western boundary and, tempted by the rich Santa Fe trade, invaded New Mexico in 1841; but the badly organized Texas-Santa Fe expedition was easily defeated by New Mexicans under Gov. Manuel Armijo.

Territorial Period.—War between the United States and Mexico broke out in 1846, and during that year the army of the west entered New Mexico under Stephen Watts Kearny. Kearny took formal possession of New Mexico at Las Vegas on Aug. 15, 1846, promising all inhabitants who would take the oath of allegiance to the United States amnesty and full citizenship, with freedom of religion and property rights. Three days later Kearny occupied Santa Fe, where he established a military government and appointed Charles Bent civil governor. Bent was assassinated in a short-lived rebellion in Taos on Jan. 19, 1847. Congress on Sept. 9, 1850, created the territory of New Mexico, extending from meridian 103° on the east to the territory of California at approximately meridian 114°. Part of the Compromise of 1850, the act included provision for Texan surrender of claims to the New Mexico panhandle or lands of the upper Rio Grande in exchange for federal payment of $10,000,000 to Texas. In 1861 the line between New Mexico and Colorado was drawn at 37° N. lat.; the territory of Arizona was created in 1863 of the western half of New Mexico.

During the American Civil War, a Confederate force under Brig. Gen. H. H. Sibley invaded New Mexico, hoping to reach the California gold fields. They advanced up the Rio Grande and took Santa Fe, but Col. E. R. S. Canby's Union troops, reinforced by the 1st Colorado volunteers, met and decisively defeated them at Apache canyon on March 28, 1862.

The period following the American occupation was marked by the solution of the Indian problem and by the economic development of the territory. The Navahos, defeated in 1865, were established in 1868 on a large reservation that crosses the New Mexico-Arizona boundary. The Apaches, in 1880, were settled on two reservations in Arizona and two in New Mexico, the Mescalero in the southern part of the state, and the Jicarilla in the northwest, lands which these tribes still hold. The United States had confirmed the Spanish and Mexican land grants to the Pueblo Indians, to individuals and to groups of Spanish settlers, but it took years and special courts to settle these complicated claims.

The settlement of the Indian troubles and the building of railways into the west brought increased population, the building of towns, the opening of mines and the introduction of cattle from Texas into eastern New Mexico. Spanish and Mexican ranchers had run sheep, and conflicts between cattle- and sheepmen over the use of water and the open range sometimes led to armed conflict. But the cattle wars common to other parts of the west were few in New Mexico. Most publicized was the Lincoln County War, 1877–80, which caused the U.S. government to dispatch Gen. Lewis (Lew) Wallace (*q.v.*) to Santa Fe as territorial governor in an attempt to restore order.

The Atlantic and Pacific railroad (later the Atchison, Topeka and Santa Fe) reached Albuquerque in 1880, building toward California. Later it connected with the Southern Pacific at Deming and ran a branch line to El Paso. New Mexico now had transcontinental roads. In 1891 a public-school system was established. English, the official language since 1846, was beginning to reach the Spanish-speaking majority of the population.

Statehood.—Constant efforts to secure statehood were finally successful; congress passed an enabling act on June 20, 1910; a constitution was drafted and approved; and on Jan. 6, 1912, New Mexico was formally admitted as a state.

Since the location of the Manhattan District project in New Mexico in 1942, atomic research laboratories and related developments have led to great population changes in the state. Establishment of scientific centres at Los Alamos, Albuquerque and Roswell caused an influx of highly trained scientists, tech- and supporting personnel, including military and service m- These new elements, coming from all the states and fro- foreign countries, have radically altered the political colo- state, and vast government expenditures (such as an annu- roll of $30,000,000 at Los Alamos) have led to a great incre- the state's per capita income.

Part of this economic advance has been due to the disco- oil, gas and uranium on Indian lands, which has made the N- Laguna and Jicarilla Apache wealthy; their wealth is own- ally and is largely devoted to education and improvement o- conditions.

Two world wars greatly affected the state's Indian and S- peoples. English has become more widely and better spoke- young men have seen the world; many have profited by - tional opportunities; in general, they have become fully integ- into the American scene.

New Mexico has voted Democratic in presidential election- cept in 1920, 1924, 1928, 1952 and 1956.

GOVERNMENT

The constitution adopted in 1911 remains the basis of the N- Mexican State government, though some amendments have - approved by the voters.

The state legislature is composed of a senate of 42 mem- (1966; formerly 37) and a house of representatives havin- members. Annual sessions were prescribed by constit- amendment approved by the voters in 1964. Representative- elected for two years and senators for four. The govern- call special sessions, and must do so on request of three-f- the legislature. The governor possesses the veto power, wh- be overridden by a two-thirds vote of the legislative member- ent and voting. The people have the right of referendum.

A direct primary was established in 1938 but in 194- changed to a preprimary nominating convention. The state- two senators and two representatives in the national congr-

The ten elective executive officials—governor, lieutenant g- ernor, secretary of state, auditor, treasurer, attorney ge- commissioner of public lands and three corporation commis- —are elected for two-year terms. They may serve two c- tive terms and are eligible for re-election after two years.

State boards, departments, agencies and commissions in- department of finance and administration, an advisory b- deposits and investments, and commissions on forest c- tion, youth, Indian affairs, alcoholism, fair employment p- a five-member highway commission, members of which - overlapping six-year terms, and a five-member board of - with six-year overlapping terms, for institutions of higher - tion.

There are 5 supreme court justices elected for terms of - years; 12 district judges, elected for six years, who als- as juvenile judges; probate judges elected in each county - years; and justices of the peace elected in each precinct - years. A 4-judge appellate court was established in 196-

The cost of state government rose from $22,300,000 in - about $250,000,000 annually in the 1950s and 1960s. A c- tional amendment limiting property tax to 20 mills neces- sales tax in 1935, a severance tax in 1937, a compensat- 1939 and a tobacco tax in 1943. The state's revenue c- marily from the sales tax, gasoline tax and oil and gas re- royalties.

POPULATION

The population of New Mexico in 1850 was 61,547; - 327,301; in 1940, 531,818; in 1950, 681,187; and in 1960 - This last figure represented an increase of 39.6% over the - lation in 1950. The population per square mile in 1960 was - compared with 4.4 in 1940 and 5.6 in 1950, and with 49.6 - United States in 1960.

Of the 1960 population, 626,479, or 65.9%, lived in i- rated places of 2,500 or more, as compared with 46.2% - and with 33.2% in 1940 when these places constituted the -

[illegible] The state has one standard metropolitan statistical area, [illegible] (Bernalillo county). This area had a population of [illegible] or 27.6% of the total population of the state in 1960.

The number of households in 1960 was 251,209 as compared with 177,128 in 1950. The average population per household had [illegible] from 4.1 in 1940 to 3.8 in 1950 and to 3.7 in 1960.

Of the total 1960 population, 5.4% was 65 years old or over, and 54.1% of the population 14 years old and over was in the [illegible]. Of the total number of employed persons, 7.1% was [illegible] in agriculture, 6.7% in mining, 9.3% in construction, [illegible] manufacturing, 4.2% in transportation and 19.2% in wholesale and retail trade.

New Mexico's ethnic composition is a fair cross section of the United States except for the fact that the usual mixture is based on Indian and Spanish elements rather than Anglo-Saxon. The state's Indians number around 55,000, and a considerable portion of the population has Spanish names. Since the first census of 1850, immigrants from the states and foreign countries have included a preponderance of Germans, with the addition of Jewish, Italian, eastern European and middle eastern persons and some orientals, mostly from China and Japan. Most of the state's English-speaking people have come from the states. Mexicans have come across the border, especially after World War II.

Both Indian and Spanish cultures have left traces in architecture and the other arts, including household furnishings, speech, [illegible] and foods.

New Mexico's Indian population in 1960 was 56,255 including Navahos, Apaches and Pueblos. Indians, declared citizens by act of congress in 1924, were granted the vote in New Mexico in 1948. [illegible] economic contribution to the state is considerable as stockmen, farmers, craftsmen and workers in many lines of industry.

Contemporary pueblo villages are Zuni, near Gallup; Acoma and Laguna, near Albuquerque; and the eastern pueblos of the [illegible] Grande and its tributaries. Mescalero, the chief Mescalero Apache village, is south of Ruidoso. Jicarilla Apache headquarters [illegible] Dulce, in northern New Mexico. The Navaho capital is [illegible] Window Rock, on the Arizona-New Mexico border.

EDUCATION

Public Schools.—Until the establishment of the public-school system in 1891 education was carried on by private and religious [illegible] schools. Progress in public-school education was rapid [illegible] New Mexico became a state in 1912.

The public-school system is governed by the state board of education, consisting of the governor, the superintendent of public instruction (appointed by the board) and ten members elected from the state's ten judicial districts. This method of choosing superintendent and board members was established by an amendment [illegible] constitution approved at the general election of Nov. 1958. Between the late 1940s and the late 1950s enrollment in the public schools more than doubled, as did school expenditures and property valuation. In the second half of the 20th century there were nearly 100 public-school systems, employing approximately 10,000 teachers, principals and supervisors. After July 1956 certification was granted only to teachers holding the bachelor's or higher degree; about one-third of all New Mexico teachers held the master's degree. Free basic textbooks were available to all pupils in grades 1 to 12.

The New Mexico Military institute at Roswell, partly supported by state funds, offers high school and junior college work, as well as military training.

Private and parochial schools enroll about 24,000 pupils. Some state control is exercised over courses of study, but the state gives no direct financial support for instruction or buildings.

In 1957 a retirement system for teachers and certain other school employees was inaugurated, with both teachers and the state contributing.

Higher Education.—The University of New Mexico at Albuquerque, chartered in 1889 and opened in 1892, consists of a graduate school and nine colleges: arts and sciences, business administration, education, engineering, fine arts, law, nursing, pharmacy and university. Regular courses are offered through two semesters, a summer session and extension courses. Other services are offered the state's schools through the college of education. Naval and air force reserve training corps units are located on the campus. The university offers the Ph.D. degree in American studies, anthropology, biology, chemistry, education, English, geology, history, mathematics, physics and Spanish.

New Mexico State university (formerly New Mexico College of Agriculture and Mechanic Arts), established at Las Cruces (State College) in 1889, offers work in schools of arts and sciences, engineering, teacher education and agriculture. New Mexico Institute of Mining and Technology in Socorro (established in 1889), includes the college, the bureau of mines and mineral resources and the research and development divisions. New Mexico Highlands university (formerly New Mexico Normal university, chartered in 1893) in Las Vegas offers extension work and grants degrees through the M.A. Eastern New Mexico university (established 1934, formerly Eastern New Mexico college), in Portales has schools of liberal arts and sciences, business and economics, music, teacher education and vocations. New Mexico Western university (established 1893; formerly New Mexico State Teachers college), at Silver City offers work in liberal arts, teacher education and vocational training.

Financial support and programs of all state institutions of higher learning are co-ordinated through the board of educational finance, appointed by the governor, which, with its executive secretary, is responsible for screening all college and university budget requirements and for approving all educational programs.

There are two private colleges in the state: St. Michael's (1947), at Santa Fe, and the College of St. Joseph on the Rio Grande (1940), at Albuquerque, both Roman Catholic.

Museums.—The Museum of New Mexico, Hall of Archaeology, and the Museum of New Mexico Art gallery are in Santa Fe, as are the Laboratory of Anthropology, the Museum of International Folk Art and the Museum of Navaho Ceremonial Art. The Roswell Museum and Art centre is at Roswell, the Taos Historical Museum and Art gallery at Taos. Albuquerque has the Old Albuquerque museum and the Albuquerque Modern museum. Old Lincoln County Court House museum is in that county seat.

HEALTH, WELFARE AND CORRECTIONS

The state supports a penitentiary (1884) at Santa Fe and a prison farm (1939) at Los Lunas, a hospital for the insane (1889) and a home for the aged (1947), both at Las Vegas; a home for the aged (1952) at Alcalde, a miners' hospital (1903) at Raton, an industrial school for boys (1903) at El Rito, moved to Springer in 1909; a girls' welfare home (1919) at Albuquerque; a school for mental defectives (1925) at Los Lunas; the Carrie Tingley Crippled Children's hospital (1937) at Truth or Consequences, a school for the blind (1903) at Alamogordo; and a school for the deaf (1887) at Santa Fe.

State provision is made for unemployment compensation. There is a joint federal and state program of financial aid to dependent children, and child welfare services of the state provide both financial and social services to dependent children.

THE ECONOMY

Agriculture.—The area east of the Rio Grande contains about four-fifths of the state's cropland. The Rio Grande valley and the area west of it, principally in Catron county, contain an acreage of about 330,000. In Curry, Roosevelt, Quay, Harding, Union and Colfax counties an average rainfall of about 14.3 in. permits dry farming; over the rest of the state, crops are dependent upon irrigation and hence are confined to the river valleys where irrigation is practicable: the Rio Grande, San Juan, Pecos, Gila, Canadian and their tributaries.

Since prehistoric times man has attempted to bring usable water to New Mexico. Early Pueblo Indians practised limited irrigation. The white settlers used windmills, artesian wells and privately financed irrigation, begun in the 1880s. The Reclamation act of 1902 ultimately resulted in a number of publicly financed dams that make possible irrigation of more than 500,000 ac. Waste and silt are problems. The Navajo dam and reservoir, dedicated in 1962 as a unit of the Colorado river storage system, was planned to irrigate about 110,000 ac. of Navaho land in the northwestern part of the state.

Value of the major crops of New Mexico approaches $100,000,000 annually; total cropland, including minor crops, is about 1,000,000 ac. The leading cash crop is cotton, followed by grain sorghums, hay, winter wheat, corn and dry beans. The chief farm animals are cattle, sheep, horses, mules and hogs; the number of horses and mules declines steadily. Livestock brings New Mexico farmers and ranchers more than half again as much income as do crops.

Industry.—Manufacturing increased slowly in the first half of the 20th century. In 1899, 175 establishments employed 2,600 persons, paid them $1,290,000 and added $2,062,000 to value by manufacture. Comparable figures in the second half of the 20th century were 700; 15,000; $72,000,000; and $150,000,000. The great increase occurred after the census of 1939, when value added by manufacture was only $8,640,000. The chief industries were food and kindred products, stone, clay and glass, printing and publishing, chemical and allied products and petroleum products.

Mining.—New Mexico is important as a source of minerals, ranking about eighth (in value of minerals produced) among the states. By the second half of the 20th century its mineral products were valued at more than $550,000,000 annually, chief among them being petroleum, natural gas and natural gas liquids, potash, copper and uranium. All of these except copper are comparatively new sources of mineral wealth, the state being known in its earlier years as a source of metals, headed by gold, silver, copper, lead and zinc. Gold was discovered in the Fray Cristóbal mountains in 1683 by Pedro de Abalos, and in 1833 the Ortiz mine, the first gold lode discovered and worked west of the Mississippi, was located. Peak gold production was reached in 1915, with 70,681 oz.; production dropped during World War I, reached a new high in 1938 and thereafter declined (to around 5,000 oz. in the 1960s). Silver mines were worked as early as the 17th century. Production reached a high point of 2,005,531 oz. in 1915 and 1,400,876 oz. in 1939 and then declined to less than 500,000 oz. in the 1960s. Copper remains a leading mineral. Lead ranged above an annual production of 20,000,000 lb. during the depression years 1929–33, then declined to 9,340,000 lb. in 1949, worth $1,470,032; by the 1960s it was mined in negligible quantities. Zinc reached a production of 119,048,000 lb. in 1943, declined to 58,692,000 lb. in 1949 and by the 1960s it, too, was of little importance. Coal production showed a similar decline from 14,133,000 tons in 1917 to 1,354,000 tons in 1949 to less than 500,000 tons in the 1960s.

The petroleum and natural gas industry did not get under way until the 1930s, but by the second half of the century oil and gas were valued at more than five times as much yearly as the next most valuable mineral product. Principal oil fields are located in Lea, Eddy, Chaves and San Juan counties. Potash mining, also dating from the 1930s, increased ten times in value between the early 1940s and the early 1960s; the state produces about 90% of the potash mined in the United States. It leads the nation in output of perlite.

New Mexico contains more than two-thirds of the United States' known uranium ore reserves, estimated at 54,900,000,000 tons averaging 0.26% uranium oxide. Production in the first year of record, 1950, was valued at about $61,000; by the 1960s it was more than $60,000,000 annually. Chief uranium-producing counties are Valencia, where the spectacular developments near Grants attracted much attention, McKinley, San Juan and Socorro.

Transportation and Communications.—In the second half of the 20th century six railroads operated in New Mexico, the most important being the Atchison, Topeka and Santa Fe railway. Commercial air transportation was provided by transcontinental and regional lines; Albuquerque was the junction airport. Improved surface highways increased from about 2,100 mi. in 1929 to 9,154 mi. in 1948 and to nearly 14,000 in the early 1960s. A motorized state police was established in 1933. The ports of entry established to collect the commercial mileage tax instituted in 1933, were placed under the state police as registration stations.

New Mexico had 16 daily papers and about 45 weeklies in the second half of the 20th century. In addition, there were many trade, professional, technical and religious publications, most of which had a state-wide circulation. The *New Mexico Historical Review*, published by the New Mexico Historical society; the *New Mexico Quarterly Review*, published by the University of New Mexico; and the *New Mexico Magazine*, a state publication, are well known. *See* also references under "New Mexico" in the Index.

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures are summarized annually in the *Britannica Book of the Year*, American edition. (E. Fe.)

NEW ORLEANS, a city of Louisiana, U.S., situated on the east bank of the Mississippi river about 107 mi. from its mouth. It is located along a bend in the river, which accounts for its popular name, "Crescent city." The boundaries of the parish (county) of Orleans and the city of New Orleans are the same with a land area of 198.8 sq.mi. The boundary line is very irregular; approximately Lake Pontchartrain on the north and Lake Borgne on the east, the two being connected by a channel called the Rigolets; the parish of St. Bernard and the Mississippi

river on the south; and the river and Jefferson parish on the west. The population of the city in 1960 was 627,525, an increase of 10% from 1950. That of the standard metropolitan statistical area (Jefferson, Orleans, St. Bernard and St. Tammany parishes) was 907,123, an increase of 32.3% in the decade. (For comparative population figures for the city *see* table in LOUISIANA: *Population*.)

The soil in the New Orleans area is an alluvial deposit from the river and therefore has its greatest elevation at the river bank, where the ground behind the levees is from 10 to 15 ft. above the mean level of the Gulf of Mexico; but the lower parts of the city are below gulf level. Built on the narrow ridge of land at the river bank, the growing city first expanded along the river front and later, the cypress swamps between the river and Lake Pontchartrain having been cleared and drained, into that area.

The river approaches New Orleans flowing eastward, turns rather abruptly to the south at the upper municipal limits, then eastward as it passes the modern city, and finally northward in one of the sharpest bends to be found in the lower river, near the site of the original city, now called the *vieux carré* or French quarter. The difficulties involved in building a city on such a site as that of New Orleans were great. Drainage, sanitation and a satisfactory water supply were not realized until nearly two centuries after the establishment of the first settlement, and in the interim yellow fever and cholera took frightful tolls. Modern engineering and sanitation finally triumphed and the city overcame these former threats to its existence.

It is noted for its mild and balmy winters; the summers are uniformly warm but extreme heat is unknown. The highest temperature recorded by the weather bureau is 102° F.; a temperature of 100° F. is seldom reached because of the cool breezes from the Gulf of Mexico.

History.—The city of La Nouvelle Orléans was founded by a French governor of Louisiana, Jean Baptiste le Moyne, sieur de Bienville, and was named in honour of the regent, the duc d'Orléans. The site chosen was on an elevation along the east bank of the river between the head of Bayou St. John and the river. Among its advantages were the higher land, accessibility by two main waterways (the Mississippi and the lakes), and by Bayou St. John for the small craft of that day. On the other side of the river it was not far to Bayou Barataria, which later was destined to become the rendezvous of the famous pirates, Jean and Pierre Laffite, and which offered access to the gulf without stemming the current of the Mississippi.

There is some doubt as to the exact date of the founding of New Orleans but it is generally given as 1718. Louisiana at that time was held by a company organized by John Law (*q.v.*), who returned it to the crown in 1731. In the meantime, however, it was proposed that the headquarters of the company should be moved away from the barren coast country and in 1722 New Orleans became the capital of the colony. At this time the city had only about 100 houses and 500 inhabitants. It was laid out in approximately a parallelogram, 4,000 ft. long on the river by 1,800 ft. in depth, divided into regular squares 300 ft. on each side. In 1724 the streets were named. The houses were rude cabins of split cypress boards, roofed with cypress bark. They were separated from one another by willow copses and weed-grown ponds swarming with reptiles. Two squares on the river front near the centre of the city were set apart for military and ecclesiastical uses. The front was the Place d'Armes, now Jackson square; the rear one was early occupied by a church. In 1726 a monastery was erected to the east of the church for the Capuchin monks, who had arrived two years earlier. A company of Ursuline nuns came to New Orleans in 1727. At the same time the Jesuits arrived and received a large tract of land from Bienville. This tract, bounded by what is now Common, Tchoupitoulas, Annunciation and Terpsichore streets, was later added to by donation and purchase and extended to Felicity street. There the Jesuits cultivated myrtle, the wax of which was then a staple article of commerce, and oranges, figs, indigo and probably sugar cane. When the order was suppressed for political reasons in 1763 its great plantation was confiscated by the king of Spain; the Jesuits did not return to Louisiana until 1837.

Many storms and disasters occurred during the early years of the city. In 1719 the river rose to a great height and the site was completely inundated to a depth of a few inches. In 1722 a hurricane destroyed 30 houses and damaged crops. German colonists who had settled on the banks of the Arkansas managed to reach New Orleans and there implored Bienville to send them back to their homes. He persuaded them to establish themselves along the river above the city, and thus was formed the nucleus of the German settlement, which to this day is called the German coast.

There were few women of good character in the colony in the early days; and many of the better class of settlers, missing their home life, desired to return to France. It thus became imperative that if the settlement was to survive, the men must have good wives to make homes for them. When Bienville left the colony in 1724, he promised to send a group of young women as soon as possible. The "casket girls" (*filles à la cassette*), so called because of the small chests of clothes and linens allotted to them by the French government, arrived in 1727 and during the period of courtship were placed under the care of the Ursuline nuns whose convent had been established in the same year. Some of the distinguished families of modern New Orleans claim to be descended from these marriages. The nuns were first domiciled in Bienville's former home but in 1730 their own house on Chartres and Ursuline streets was completed. This is one of the oldest buildings in the United States west of the Alleghenies.

In 1763 the treaty of Paris was concluded between France and England, by which England gained all the territory east of the Mississippi except the Isle of Orleans. By a secret treaty of Nov. 3, 1762, Louis XV had given the Isle of Orleans and all of Louisiana west of the Mississippi to his cousin, Charles III of Spain. It was not until Oct. 1764 that the French king notified the governor of the colony of the transfer and ordered him to surrender Louisiana to accredited Spanish commissioners when they should present themselves. The news was not well received in New Orleans. In 1783 the treaty of Paris confirmed Spain in possession of this territory and granted free and open navigation of the Mississippi river to the subjects of Great Britain and the United States. In 1788 and again in 1794 fires destroyed large portions of the city. By the first, 19 squares were devastated and 856 houses were burned. The second fire destroyed 212 houses and caused a loss estimated at $2,600,000. Rebuilding with brick instead of wood resulted in a more permanent city. During this period the Spanish merchant, Almonaster y Rojas, was the greatest benefactor of New Orleans; he gave freely of his private fortune for many purposes. He rented in perpetuity the squares flanking the Place d'Armes and erected a row of brick buildings to be used as shops and retail stores. These were replaced in 1845 by the Pontalba buildings, which bear the name of their builder, Baroness Pontalba, Rojas' daughter. He rebuilt the Charity hospital, which had been destroyed by a hurricane, and a chapel for the Ursuline nuns. Through his generosity the cathedral was completed in 1794; it was constructed of bricks and had much the same appearance as today except in details of the belfry and towers. A town hall, or hall of the Cabildo, presented to the city in 1795 was the seat of Spanish rule and is now the state museum.

Before the cultivation of sugar cane the staple crop of Louisiana had been indigo but a caterpillar plague in 1793 and the two years following caused such extensive damage that its cultivation was temporarily abandoned. In 1794 Étienne de Boré, whose plantation is now within the city limits, succeeded in making granulated sugar and thereafter the production of sugar cane increased considerably. By the treaty of Madrid, signed in Oct. 1795, Spain and the United States agreed that New Orleans should be open to the Americans as a port of deposit for three years; the produce was to be free of duty but a reasonable price for storage was to be paid. The commerce of New Orleans increased greatly and the levee was the scene of noisy, bustling business.

From 1800 to 1803 Louisiana was again a French possession and in 1803 the territory was purchased by the United States (*see* LOUISIANA PURCHASE). This transfer had a further bene-

ficial effect on trade. The first half of that year showed an increase of 37% in tonnage over that of 1802; exports exceeded $2,000,000 and imports $2,500,000. The flatboat trade with the upper valley also increased enormously. Above the *vieux carré* commercial houses were erected and this newer portion of the city gradually became a business centre. Many of the street names are reminders of the first owners or of the first use of the locality. Gravier street bears the name of its original owner, Poydras that of a philanthropist; Magazine was so named because of the great tobacco warehouses on Magazine and Common, and Camp street because of a slave camp between Poydras and Girod. Along the Bayou St. John road there was an aristocratic suburb.

In 1805 New Orleans was incorporated as a city and the people exercised their right of suffrage for the first time in electing aldermen. Between 1803 and 1810 the population more than doubled with the arrival of many whites, mulattoes and slaves from Cuba, Santo Domingo and other islands of the West Indies. The population of the city has been cosmopolitan from the beginning, and an unusual characteristic up to the time of the American Civil War was the presence of considerable numbers of *gens de couleur* —"free people of colour," many of whom themselves owned slaves. After the war, however, the distinction between "free men of colour" and "freedmen of colour" (the former slaves) was lost and the *gens de couleur* lost the social advantages they had held.

During the War of 1812 New Orleans was not endangered until the autumn of 1814, when a British fleet entered the Gulf of Mexico. Gen. Andrew Jackson, commander of the U.S. army in the southwest, reached the city on Dec. 1 and immediately began preparations for its defense. Because of slow communications neither the British nor the Americans had received notice of the conclusion of the war by the treaty of Ghent, signed two weeks previously, when the British attacked on the morning of Jan. 8, 1815. The outcome of the brief battle, a decisive victory for the Americans, had considerable psychological value and greatly advanced the political fortunes of Jackson. (*See* also WAR OF 1812.)

Commerce on the Mississippi was greatly stimulated by the advent of steam navigation; the first steamboat to descend the river was the "New Orleans," which arrived on Jan. 10, 1812, on its maiden trip from Pittsburgh, Pa. The river trade was carried on in spite of the danger from sandbars on entering the river. In the space of a few weeks, in 1852, 40 ships went aground at the entrance to the river. The terrible yellow fever epidemics of 1853–55 reduced the volume of trade, which was regained, however, and a high-water mark reached in 1857, to be followed by a financial crash which was disastrous to the business houses of New Orleans.

Louisiana seceded from the union on Jan. 26, 1861. New Orleans was recognized as a strategic point by the authorities at Washington and two expeditions started to secure the Mississippi for the union: Gen. U. S. Grant was to descend the river and Adm. David Farragut and Gen. Benjamin F. Butler were to ascend it. The city had sent 5,000 soldiers to the defense of the northern line of the Confederacy but the southern government seemed oblivious to the importance of holding New Orleans. While Grant was endeavouring to push his way downstream, Farragut was entering the river from the gulf with a fleet of 43 vessels. The assistance asked by Gen. Mansfield Lovell could not be given by the Confederacy. An attempt was made to obstruct the passage of the Federal fleet by cables put across the river below the city, but New Orleans was captured by Farragut on April 25, 1862, and the city front blazed with the fire from thousands of bales of cotton and hogsheads of sugar and molasses which were burned to prevent their falling into the hands of the Federals.

General Butler with 15,000 soldiers took charge of the city on May 1, 1862. The mayor was removed from office and a military commandant appointed in his place; the city council was replaced by the bureau of finance and the bureau of streets and landings. Butler's rule in New Orleans was execrated by the people of the city; his removal before the end of the year curtailed some of the worst excesses of the occupation.

The years 1865–77, the period of Reconstruction, were a time of racial and political strife. In the wake of the war came a host of undesirables seeking fortunes by easy means—the "carpetbaggers," who with their southern friends and associates called "scalawags" gained control of the city government through leadership of the voting population, largely composed of the newly enfranchised Negroes. Much of the property of the city disappeared; extravagant expenditures reached $6,961,381 in 1872 and the bonded indebtedness $21,000,000, paying up to 10% interest. The white men of the city, who were virtually deprived of the ballot by all the restrictions placed upon its exercise, formed the "white league" for the expulsion of the "carpetbag" government and the restoration of white supremacy. Riots broke out frequently and there were armed encounters between the white league and the metropolitan police. The white league made a number of gradual gains and the situation in general aroused northern sympathies, so that in 1877 home rule (which meant in effect white supremacy) was restored in New Orleans by the federal government. These Reconstruction experiences not unnaturally left a bitter aftermath in New Orleans and for many years the Negro was in one way or another almost totally disenfranchised. In the 20th century, however, substantial gains were made, particularly through reform measures that benefitted the economically underprivileged, white or Negro, and in the governor's election of 1959, out of a total registration of 205,000 for the city, 34,000 Negroes were registered voters and an estimated 85%–90% voted. In the early 1960s, however, there was considerable opposition by white-supremacy groups and the state legislature to the racial integration of New Orleans schools.

Municipal improvements made slow progress during restoration times and for many years after; the city undertook the operation of the waterworks in 1869; a drainage system was proposed in 1871 but proved too expensive to be carried out; in 1871 the board of park commissioners bought the Upper City park, now Audubon park. The population in 1860 was 168,755 and had increased by 1870 to 191,418. During this decade many freed Negroes had come to the city from country districts. In 1870 the fifth and sixth districts were added by the annexation of the town of Algiers on the opposite bank of the river and of Jefferson City a town adjoining the fourth district. In 1874 Carrollton was admitted as the seventh municipal district, and New Orleans attained its present limits.

The history of New Orleans in the late 19th and early 20th century is largely its commercial and industrial expansion, and a building program discussed in *Government* below. The channel at the mouth of the river was deepened in the 1870s; by 1883 the city was linked by railroad with the west and north and formed the hub of the state network, as it still does. Although New Orleans was and is primarily a commercial city, there has been increasing development of industry in the 20th century (see *Commerce, Transportation and Industry* below).

In the spring of 1927, the city was saved from a great Mississippi river flood by blasting the levee at Poydras, about 15 mi. below the city, on April 29. This operation sacrificed the adjacent parishes of St. Bernard and Plaquemines at a cost to the city of approximately $5,000,000. To avoid similar danger in the future the Bonnet Carre spillway was constructed about 35 mi. above the city to remove 250,000 sec.-ft. of water from the river during excessive floods and deliver it into Lake Pontchartrain. Protected by this device and similar safeguards on the lower river, the city survived an even greater flood in 1945 without mishap or any emergency action.

Population Characteristics.—Of the 1960 population of the city 60.9% was native-born white, 2.3% foreign-born white and 39.1% Negroes, including mulattoes and others of mixed blood. Among the foreign-born, almost every nationality is represented; the Italians, who came in considerable numbers after 1900, are the most numerous. The creoles—by current usage the descendants of the original French and Spanish settlers—are perhaps the group for which New Orleans is best known. (Until late in the 19th century, this term as used in New Orleans meant persons born in the city, so that there were "creole" Anglo-Americans,

Irish and Germans as well as "creole" Latins.) Although numerically less important than popularly believed (both in the 19th and 20th centuries large numbers of Anglo-Americans from southern and northern states and of immigrants from other European countries settled in the city) the Latin creoles still help give New Orleans a distinctive atmosphere among U.S. cities and the French language continues to be used. When a considerable number of Americans of Anglo-Saxon descent began settling in the city in the early part of the 19th century they built a quarter for themselves upstream from the *vieux carré*, the upper boundary of this settlement being Canal street. In the 20th century, however, the lines were not nearly so strictly drawn.

Government and Administration.—The city government was at first carried out by a mayor and administrators, seven in number. In 1912, by act of the legislature, the commission form of government was adopted; the mayor became commissioner of public affairs. Four other commissioners had charge of public finances, public safety, public utilities and public property. In 1950 the legislature restored a mayor-council system, increasing the number of commissioners to seven, each elected by a separate municipal district.

Municipal Works.—During the administrations of deLesseps Morrison, reform mayor who in 1946 defeated the Old Regular Democratic machine which had long controlled local government, a tremendous physical rehabilitation of the city was effected. Besides major transportation innovations, such as bridges (discussed below), 22 new overpasses eliminating 144 grade crossings were constructed, a central, modern railroad terminal and an extensive new municipal centre, consisting of six major buildings including the city hall, library, state supreme court building and a state office building were erected in the heart of the city on the site of a former slum area; many miles of streets were widened and improved and a program was launched to rehabilitate 45,000 substandard buildings over a ten-year period.

The location of New Orleans presents certain problems in regard to such municipal concerns as water and sewage. The entire city, except for its levees, is below the river high-water mark while a large portion of it is below that of Lake Pontchartrain. Combined with these difficulties New Orleans has heavy rainfall; occasionally more than 3 in. in 1 hour, 7 in. in 5 hours and 9 in. in 12 hours, having been experienced. As a result of the occasional excessive rainfalls, it has been necessary to provide large canal systems to convey the water to and from the pumping plants, and 11 pumping stations for the removal of storm water have been built. The average annual rainfall is more than 50 in.; the topography is such that the runoff must be removed by pumping. The sewage of the city is collected separately from the drainage and is finally discharged into the Mississippi, where the dilution is so great that it is not noticeable farther downstream. Like the drainage, the sewage has to be pumped, much of it through two or more lifts, and this is accomplished by electric pumping stations operating automatically.

Commerce, Transportation and Industry.—Among North American ports New Orleans is second only to New York in most categories. It accommodates more than 80 steamship lines and about 4,000 vessels enter the port annually. Located at the intersection of the Gulf Intracoastal waterway and the Mississippi river, it handles both internal river traffic and foreign trade. The limits of the port include a frontage of 51 mi. on both sides of the river and 11 mi. on the Industrial canal, which connects the river with Lake Pontchartrain; 20 mi. of publicly owned wharves, steel sheds, warehouses, grain elevators and similar facilities are maintained.

By the middle of the 20th century New Orleans had regained the pre-eminence as a port which it enjoyed before the Civil War but the most significant economic development in the post-World War II period was a great increase in industry along the entire lower river south of Baton Rouge. This boom was set off mainly by the discovery of great quantities of oil and sulfur on the Louisiana tidelands, petrochemicals being the most important of the new industries. Other factors responsible, besides the natural advantages of a port, were the accessibility of a cheap fuel, natural gas; free-water supply (300,000,000,000 gal. of water pass New Orleans each day at high river stages, twice as much as is used by the rest of the nation for all purposes); and the apparently successful control of floods on the lower river.

New Orleans is also served by trunk railroads, airlines, barge lines, truck lines, and a public belt railroad 128 mi. in length. It has three airports: the New Orleans airport on the lake, for private planes; the Moisant international airport in Jefferson parish for commercial traffic; and Callender field, across the river below the city for military craft.

In 1928 the first bridge across Lake Pontchartrain, 25,000 ft. long, was completed. Shortly thereafter bridges across Chef Menteur and the Rigolets provided a more direct line to the Gulf coast. In 1935 the Huey P. Long bridge across the Mississippi 5 mi. above the city was opened to traffic, and in 1958 a second river bridge in the heart of the city was completed. In 1957 another bridge across Lake Pontchartrain, 24 mi. long, was put into operation.

Education and Cultural Activities.—The New Orleans public-school system includes kindergarten, elementary and high schools, evening schools and trade schools. In addition there are in the city over 100 nonpublic schools, both private and parochial (mostly Roman Catholic; some Lutheran). Uniform textbooks purchased by the state department of education are supplied to all nonpublic schools and their classes are conducted under a curriculum approved by the department. Largest of the strictly private schools is the Isidore Newman school, founded in 1903, which is coeducational.

Universities and Colleges.—New Orleans has several distinguished colleges and universities. The history of Tulane, a private university, dates from the foundation of a medical college (called the Medical College of Louisiana) in 1834. It was chartered in 1835 and in the following year issued the first degree in medicine conferred in the southwest. Other departments were added and in 1847 the institution took the name University of Louisiana; in 1884 it was renamed in honour of Paul Tulane, who had been a merchant in New Orleans for many years and who had made a very large gift of money to the institution. The university now includes a college of arts and sciences, schools of architecture, business administration, engineering, law, medicine and social work, and H. Sophie Newcomb Memorial College of Tulane university, for women, chartered in 1886.

Loyola university, a Roman Catholic university founded in 1904, is coeducational in its professional departments and for men in other departments. In addition to arts and sciences it has schools of dentistry and law and colleges of pharmacy, music and business administration.

Dillard university, established in 1930 by the merger of two earlier institutions, is affiliated with the Congregational Christian and Methodist churches. It grants the B.A. degree and the B.S. in nursing. Xavier University of Louisiana, a Roman Catholic university, began as a high school in 1915 but became a teachers' college two years later and has since added liberal arts and premedical departments and a graduate school. Originally for Negroes and Indians, it is now open to all races. St. Mary's Dominican college is a Roman Catholic liberal arts college for women, established in 1860. Louisiana State university in New Orleans, an integral part of the state university in Baton Rouge (*see* LOUISIANA: *Education*), opened in 1958 with a freshman class and added an additional class each of the following years until a four-year program was in operation.

Other Institutions.—The Isaac Delgado Museum of Art in City park was established by a gift from Isaac M. Delgado in 1911. The annual exhibition of the Art association is an important event. The Cabildo houses an important historical museum containing much of interest and value pertaining to the history of Louisiana and New Orleans. The Presbytère, facing Jackson square on the side of the Cathedral of St. Louis, contains a valuable museum of natural history, principally relating to Louisiana. The Confederate Memorial hall, located on Camp street, contains relics of the Civil War. The Tulane university museum occupies the entire third floor of Gibson hall; it contains petrological, paleon-

tological, zoological and anthropological sections. Several galleries exhibiting contemporary art are to be found in the *vieux carré*. A civic symphony has been established and the Philharmonic society brings the great contemporary musicians and concerts to the city. The Metropolitan Opera comes annually, thus reviving interest in French opera which was originally heard in New Orleans long before it was heard in New York. The Department of Middle-American research, created in 1924 as a department of Tulane university, has a museum and library, field work and publications as its primary activities. The library of 40,000 items and the museum contain manuscripts, documents and other material relating to Mexico and Central America from expeditions and purchases which are being constantly increased. The institute has a permanent endowment of $300,000. The New Orleans spring fiesta was organized in 1937 and has created tourist interest in art, architecture, gardens and local traditions. The city has more than 12 major hospitals of various types, the largest of which is the Charity.

Journalism.—New Orleans has long been an important newspaper and publishing centre. The *New Orleans Picayune* was founded in 1837, the *Daily Times* in 1863, the *Daily Democrat* in 1875. The two latter formed the *Times-Democrat* in 1881 and this and the *Picayune* became the *Times-Picayune* in 1914. The *Daily Item* began publication in 1877, later becoming the *New Orleans Item*. The *Daily States*, started in 1880, was purchased by the Times-Picayune company in 1933 as an afternoon and combined Sunday publication. In 1959 the same company bought the *Item* and merged it with the *States*. This exemplified the tendency, common in the larger U.S. cities, of consolidating ownership of newspapers and thereby eliminating competition; many observers felt that as a result the press in New Orleans in the latter part of the 20th century was characterized mainly by its anemia.

Among the many writers associated with New Orleans Lafcadio Hearn and George W. Cable are probably the best known. John James Audubon, the artist-naturalist, made his home there for several years.

Recreation and Tourist Attractions.—New Orleans is well known as the home of the largest and most colourful Mardi Gras celebration in the United States. The carnival season extends from Twelfth Night (Jan. 6) to Lent and is climaxed by the festivities of Mardi Gras, "fat Tuesday" before Ash Wednesday. Out of the simple idea of masked revelry in the open streets has developed a complex organization of gorgeous torch-lighted parades and balls. The first carnival parade (as distinguished from the Mardi Gras celebration) was held in 1827 by masked students who had recently returned from Paris. In 1837 and 1839 the first processions with "floats" were held in New Orleans. The regular annual pageants, almost uninterrupted except during the Civil War, date from 1857, when the "Mystic Krewe of Comus," the oldest of the carnival organizations, was formed. There are a number of other organizations, secret societies and clubs which assume responsibility for certain portions of the Mardi Gras celebration, which extends for several days. Most of the balls are private but the public parades are a major tourist attraction.

Other tourist attractions are the *vieux carré* and the Garden district. In the *vieux carré*, Spanish and French influences combined to form a unique creole style of architecture; characteristic features of the buildings in the area (many of which are now preserved as historic monuments and are open to the public) are enclosed rear courts, balconies and extensive use of wrought-iron railings and cast-iron "lace." The Garden district, originally a residential district for the American aristocracy who arrived after 1803, is between St. Charles avenue and the river; it is characterized by handsome homes, mostly Greek Revival in style. The city is also famous for its fine restaurants.

Extensive plantings of azaleas and camellias have beautified the city and it is well supplied with parks. Audubon park, with 234 ac. is situated in the upper portion of the city and contains a statue of Audubon. The original area of City park was about 1,400 ac., later developed and beautified further. The area was added to by hydraulic dredging on the lake shore front between West End and beyond Bayou St. John on the east. A large municipal yacht harbour was constructed at West End. Many miles of boulevards and driveways, with parks and bathing beaches, were also developed as residential areas.

The salubrious climate, the Gulf of Mexico and the hundreds of bayous, rivers and lakes in southern Louisiana make New Orleans a sportsman's paradise. Opportunities for sailing, boating, hunting and fishing, both salt and fresh-water, are excellent. Tarpon are frequently caught within the city limits and numerous fishing rodeos are held annually.

During the Christmas holidays a Mid-Winter Sports carnival is held, ending with the Sugar Bowl football game on New Year's day. The Fair Grounds race track opens its season each year on Thanksgiving day; races are held every day except Sunday for three months. As matters of incidental interest it may be mentioned that jazz (*q.v.*) derived most of its original impetus from the Negro musicians of New Orleans and the term Dixie (*q.v.*) is said to have originated there.

(G. M. Ca.)

NEW PHILADELPHIA, a city of eastern Ohio, U.S., about 22 mi. S. of Canton; the seat of Tuscarawas county. Located in Ohio's unglaciated hill country in the valley of the Tuscarawas river, the city and its surrounding countryside comprise one of the most scenic and historic areas in Ohio. Just south of the city, the Moravian missionary, David Zeisberger (1721–1808) founded the mission village of Schoenbrunn ("beautiful spring") among the Delaware Indians in 1772. There the first church and schoolhouse in Ohio were built, but in 1777 the settlement had to be abandoned on account of the hostility of neighbouring Indians. The site of Schoenbrunn, discovered in 1923, has been restored. To the north, Ft. Laurens, the only Revolutionary War fort in Ohio, was built in 1778, while nearby a band of German Separatists in 1817 established the communal village of Zoar which lasted until 1898.

New Philadelphia itself was founded in 1804 by John Knisely on lands set aside by the federal congress in 1796 as the United States military district, tracts within which were to be distributed to veterans of the Revolutionary War. Named in honour of Philadelphia, Pa., the community grew slowly at first, the population reaching but 1,413 by 1850. After the American Civil War, however, growth was more rapid, principally because of the development of large deposits of coal and clay in the immediate area which enabled it to emerge as one of the important small industrial centres of Ohio. Principal industries include the manufacture of mining and road equipment, tapered roller bearings, tools, batteries, spark plugs and ceramics.

Serving as headquarters for the Muskingum Watershed Conservancy district, New Philadelphia is in the heart of one of the nation's most important conservation, flood control and recreational areas. New Philadelphia was incorporated as a village in 1815 and as a city in 1896. For comparative population figures see table in OHIO: *Population*. (P. R. S.)

NEW PLYMOUTH, a municipality and seaport on the west coast of the North Island, New Zealand, chief town of the land district of Taranaki, 251 mi. N.N.W. of Wellington by rail. Pop. (1961) 29,368 (urban area 32,387). The town is noted for its parks and gardens, and the district is the chief dairy centre of New Zealand. The settlement was founded in 1841 by the Plymouth company under the auspices of the New Zealand company and consisted chiefly of emigrants from Devonshire and Cornwall. Mt. Egmont (8,260 ft.), 18 mi. S. of New Plymouth, is well known

for its winter sports and is the centre of Egmont National park (128 sq.mi.).

NEWPORT, a market town, municipal borough and county town of the Isle of Wight, England. Pop. (1961) 19,482. It is near the centre of the island, at the head of the wide estuary of the Medina river, 5 mi. S. from its mouth at Cowes. Industries include plastics and woodwork, milling, brewing and mineral water (soft drink) manufacture. Newport is the centre of the island's agriculture and its harbour is used for import and export business. The church of St. Thomas of Canterbury was rebuilt in 1854 in the Decorated style; the county hall was built in 1938 and the town hall (1816) was designed by John Nash. The grammar school was founded in 1614. The Albany barracks, Parkhurst prison and Camp Hill Borstal institution, the last two in Parkhurst forest, lie north of the town. Newport was probably a Roman settlement, then known as Medina; remains of a villa in good preservation were found in 1926. There are no traces of Saxon occupation and no evidence that Newport became a borough before the reign of Henry II. The first charter was granted by Richard de Redvers between 1177 and 1184, and a second, by Isabel de Fortibus, was confirmed by successive kings. The borough was incorporated by James I in 1608 and the final charter, by which Newport was governed until 1835, was granted by Charles II in 1661. It was represented in parliament in 1295, but no other return was made until 1584, when it regularly sent two members. From 1867 to 1885 it sent one but in 1885 its representation was merged in that of the island. The Saturday market dates from 1184, and there is a Tuesday market. Because of its facilities for trade, Newport early superseded Carisbrooke (*q.v.*) as the capital of the island.

NEWPORT (CASNEWYDD-AR-WYSG), a municipal, county and parliamentary borough of Monmouthshire (*q.v.*) is the easternmost of the Bristol channel seaports that serve the mining and industrial area of south Wales and Monmouthshire. Though not the county town, it is the administrative centre of Monmouthshire. Newport lies on the river Usk, 4 mi. from its confluence with the Severn, and it is 12 mi. N.E. of Cardiff and 24 mi. S.W. of Monmouth by road. Pop. (1961) 108,107.

Giraldus Cambrensis called it Novus Burgus ("New Town"). The burgesses obtained a monopoly of trade and self-government evidenced by a charter from the earl of Stafford in 1385. A charter of the duke of Buckingham, the landlord in 1476, shows the reeve to have been superseded by a mayor. In 1623 James I gave the townsmen their first royal charter, which served until the Municipal Corporations act of 1835. The town was the scene of Chartist riots in 1839 and Chartist bullet marks are preserved in the pillars of the Westgate hotel. County borough status was achieved in 1891 and one member of parliament is returned.

Two bridges over the river Usk form the main gateway for road traffic from London to south Wales. The new cable cantilever bridge, the first of its kind in Britain, was completed in 1964. The old parish church of St. Woolos became the procathedral of the diocese of Monmouth in 1921. Between the Lady chapel and the nave is a splendid 12th-century Norman arch. The square, three-story tower (*c.* 1480) is attributed to Jasper Tudor, duke of Bedford. The Norman castle (*c.* 1126) stands in ruins and nearby in High street is a fine old Tudor building named after the original Murenger's house. The main shopping centre comprises High street, Commercial street, Bridge street and Dock street. The new civic centre at Clytha park, partly opened in 1940, now contains the main offices of the town council. The Newport and Monmouthshire Joint College of Technology is an imposing modern building (1958) near the civic centre. The Central Library, Museum and Art gallery are situated in Dock street. The provision market built in 1888 lies between Dock street and High street. Belle Vue at Cardiff road and Beechwood at Chepstow road are the main parks. A 245-ft.-high transporter bridge, opened in 1906, spans the river near the docks.

The modern port grew from the local coal and iron export trade and the present Alexandra docks comprise the North and South docks forming a continuous deepwater area of 125 ac. with 4 mi. of quays and six transit sheds providing 234,000 sq.ft. of covered floor space. There are three commodious dry docks. The principal exports are manufactured iron and steel products, machinery, vehicles and vehicle parts, galvanized iron, tinplate, coal and miscellaneous goods. Imports are primarily iron ore and nonferrous ores such as bauxite, petroleum, semimanufactured iron and steel, timber, pitwood, aluminum and building and roadmaking materials. The principal industries, apart from shipping and export packing, produce steel, structural steelwork, aluminum, chemicals, electrical goods, clothing and fibreboard.

Newport is a good tourist centre for the Wye valley, the Vale of Usk and the northern shore of the Severn estuary.

(R. W. H. H.)

NEWPORT, a city of northern Kentucky, U.S., on the Ohio river, near the mouth of the Licking, opposite Cincinnati, O.; one of the seats of Campbell county and a part of the Cincinnati standard metropolitan statistical area (*see* CINCINNATI). Across the Licking is Newport's sister city, Covington.

The first settlement, planned in 1790 by Hubbard Taylor, a young soldier, was named in honour of Christopher Newport, commander of the first ship to reach Jamestown in 1607. In 1795 Newport was incorporated as a village and in 1835 as a city. The only antislavery newspaper published in Kentucky during the 1850s was edited in Newport by William Shreve Bailey. It was given various names by its editor, the last being *The Free South*. On Oct. 28, 1859, after a proslavery mob threw his presses and type into the street, Bailey took his paper across the river to Cincinnati.

Newport experienced its greatest growth in the 1880s and 1890s because of the influx of many German settlers and the completion of bridges to Cincinnati, which promoted its development as a residential suburb of that city. A metal fabricating centre, Newport was the scene of a seven-year (1921–28) strike by steelworkers. In 1932 Newport adopted a council-manager form of government. For comparative population figures *see* table in KENTUCKY: *Population*. (W. F. ST.)

NEWPORT, a city of southeastern Rhode Island, U.S., about 30 mi. S.S.E. of Providence, occupying the southern end of the island of Rhode Island (or Aquidneck) in Narragansett bay; a port of entry and the seat of Newport county. It is a place of historic interest, important formerly as a fashionable summer resort for some of the wealthiest U.S. families and in the second half of the 20th century for its naval installations.

From the harbour on the west, the city rises up a gentle hillside to a plateau at about 250 ft. elevation. Famous for its mild climate the year round, it attracted southerners and West Indian planters in summer as early as the first quarter of the 18th century. The city itself is a community of contrasts. An old section, dating from the colonial period, consists of historic buildings and homes set on narrow streets which climb the slope eastward from the harbour. Along Newport's Bellevue avenue, which runs through the heart of the island, and around the southern coast line can be seen the magnificent mansions of 19th- and early 20th-century millionaires. Some of these have been boarded up while others have been converted for church and school use. A few are still used as summer homes.

Until 1900 Newport was one of Rhode Island's two capital cities, sharing that honour with Providence. The Old State house or Old Colony house (1739), one of the most interesting colonial buildings in the state, still stands at the head of the old Parade, now Washington square. Not far away are such historic structures as Trinity church (1725); Touro synagogue (1763), the oldest in America (designated a national historic site in 1946), famous for the architectural beauty of its interior; and the Redwood library (1750).

The old section known as "the Point," on the harbour front, contains many fine homes of colonial merchant princes. Some of these homes have been restored and opened as museums by the Preservation Society of Newport county. One such is the Hunter house, furnished with outstanding antique furniture, much of it produced by the famous Newport dynasty of colonial cabinetmakers, the Townsends and Goddards. Also restored and opened to the public is the pre-Revolutionary White Horse tavern.

In Touro park at the top of the hill is Newport's most enigmatic structure, a stone tower set on stone pillars. Long thought to be a vestige of the Norsemen's visits to America before Columbus, it is now held by most responsible archaeologists and historians to be the remains of a 17th-century windmill built by Benedict Arnold, one of the early settlers and an ancestor of the traitor of the same name.

Other points of interest include the Newport casino, scene of an annual grass-court tennis tournament and the American Lawn Tennis association's tennis "Hall of Fame," and "The Breakers," former summer home of Cornelius Vanderbilt, now open in summer as a museum.

Newport was founded in 1639 by a group of refugees from the Antinomian controversy (*see* HUTCHINSON, ANNE), in Massachusetts who had first settled the year before at the north end of the island in the present town of Portsmouth. Following a schism in that settlement a group led by William Coddington moved to the south end of the island and established Newport which, because of its excellent harbour and strategic position for water-borne commerce, soon became one of the richest and most flourishing cities in colonial America, surpassed only by Boston, Philadelphia and New York city.

The British occupation of Newport during the American Revolution, which resulted in a flight of almost all the leading merchants to the mainland, followed within a few decades by the shift of Rhode Island's income from commerce and shipping to textile mills and other manufacturing, brought about the economic decline of the city. But its splendid climate and its charm remained unchanged and right after the American Civil War its rise as a summer resort was spectacular.

In the second half of the 20th century manufactures included electrical instruments and appliances but the largest industry was the complex of naval installations. Comprised of the Naval War college and the several components of the Newport naval base, which includes the naval station (formerly the naval training station), the naval underwater ordnance station (formerly the naval torpedo station), the Melville net and fuel depot in nearby Portsmouth and the naval hospital. The naval station, formerly used to train recruits, consists of the officers candidate school and fleet training centre, the legal school, chaplains indoctrination school, WAVES general line school and navy supply school.

Printing in Rhode Island was begun at Newport in 1727 by James Franklin, an older brother of Benjamin, and the colony's first newspaper was published there in 1732. It failed shortly but in 1758 James Franklin, Jr., established the *Newport Mercury*, still published as a weekly.

Newport, beginning in 1954, was the home of an annual jazz festival, generally held over the Independence day week end. Newport is the seat of Salve Regina college (Roman Catholic, 1947) for women.

Chartered as a city in 1784, Newport resumed the town form of government in 1787, but again became a city in 1853. In 1953 Newport adopted a council-manager form of government. For comparative population figures *see* table in RHODE ISLAND: *Population.* (B. F. S.)

NEWPORT BEACH, a city of Orange county in southern California, U.S., 35 mi. S.E. of Los Angeles. It includes the communities of Newport Beach and Balboa on a four-mile-long sandspit between lower Newport bay and the Pacific ocean, Lido Isle and Balboa Island in the bay, and Corona del Mar and Newport Heights on terraces above the northeast shores of the bay. The area is popular as a recreational resort developed around yachting, sportfishing and beach activities, and as a residential community for commuters to Long Beach and Los Angeles. Industries include boatbuilding and repairing, fish canning and packing and the manufacture of electronic components and plastics. The bay itself was a port for Yankee skippers during the Spanish and Mexican periods of California history and from 1872 to 1898 it achieved some local significance as a commercial port. Incorporated in 1906, the city adopted a council-manager form of government in 1946. For comparative population figures *see* table in CALIFORNIA: *Population.* (R. A. K.)

NEWPORT NEWS, a city and port of entry in the tidewater region of southeastern Virginia, U.S., on the north side of the great harbour of Hampton Roads (*q.v.*) and the James river. Pop. (1960) 113,662; Newport News-Hampton standard metropolitan statistical area (Newport News and Hampton cities and York county), 224,503. (For comparative population figures see table in VIRGINIA: *Population.*)

Settled by Daniel Gookin, who arrived from Ireland in 1621 with 50 colonists, the area was already known as Newportes Newes. There is no satisfactory explanation of the origin of this unusual name. Newport News remained a tiny hamlet until 1880 when it was chosen as the Atlantic deep-water coal shipping port for the Chesapeake & Ohio Railway system. Two years later the town was laid out and in 1896 it was incorporated as a city. During World War I Newport News was an important port for supplying the Allies and also served as a major supply and embarkation port for U.S. forces in 1917–18. In World War II it was headquarters for the Hampton Roads port of embarkation. In 1952 Newport News was made administratively independent of Warwick county in which it was located. That same year Warwick county was incorporated as the city of Warwick, and in 1958 Newport News and Warwick merged as the city of Newport News. In 1920 the city adopted a council-manager form of government. Its port facilities, along with those of Norfolk, Portsmouth, Chesapeake (*qq.v.*) and Hampton, are under the jurisdiction of the Virginia State Port authority of Hampton Roads, created in 1926. Modern pier facilities can handle more than 30,000,000 tons of coal per year as well as ore, bulk liquids and general cargo. The Newport News Shipbuilding and Dry Dock company, founded in 1886, has one of the largest and most complete shipyards in the world. Among the vessels built there were the luxury liners "America" and "United States," the giant aircraft carriers "Forrestal" and "Enterprise" and the submarine "Robert E. Lee," designed for firing Polaris guided missiles. Both the "Enterprise" and the "Lee" were nuclear powered. In addition to shipbuilding and repairing, Newport News' industries include railroad shops, oil refineries, fish processing plants and the manufacture of textiles, paper products, radar and electronic equipment and mica products. Among points of interest in the city is the Mariners' museum (1930), containing a collection of ships' figureheads, ship models, anchors, deck and navigation gear, volumes of sea lore, maps, charts and globes. (M. Bx.)

NEWQUAY, an urban district and seaside town in the North Cornwall parliamentary division of Cornwall, Eng., 20 mi. W.S.W. of Bodmin by road. Pop. (1961) 11,877. Area 7.2 sq.mi. Newquay, on the tidal Gannel, is almost entirely a modern resort town, having grown since the mid-19th century from a small fishing village. It stands mostly on bold cliffs overlooking sandy beaches, sheltered on the west from the Atlantic by Towan headland. The golf course overlooks Fistral bay. The climate is equable and tropical plants grow in the Trenance valley. The small harbour, in the shelter of Towan headland, is now used only by local fishing and pleasure boats.

NEW QUEBEC (NOUVEAU QUEBEC), the Quebec part of the great Labrador-Ungava peninsula. It comprises the entire peninsula between Hudson and James bays and the Coast of Labrador portion of Newfoundland, north of the general line of the Eastmain and Hamilton rivers. Formerly the Ungava district of the Northwest Territories, it was annexed to Quebec in 1912; the boundary with Newfoundland was established in 1927. Development of immense iron deposits began in the 1950s. *See* LABRADOR-UNGAVA; QUEBEC.

NEW ROCHELLE, a city of Westchester county, N.Y., U.S., on Long Island sound about 14 mi. N.E. of New York city. Founded in 1688 by a group of Huguenots who had fled persecution in France, it became in modern times largely a residential city for those who work in the nearby metropolis. The few local industries produce a variety of light products including surgical instruments, television parts, plumbing supplies and electrical machinery. Many parks lie within the city, while Glen Island nearby on the sound provides 108 ac. of recreational space. There are two colleges, both Roman Catholic, located there. The Col

lege of New Rochelle (women) was founded in 1904, while Iona college, a business and liberal arts institution for men, dates from 1940. Named for La Rochelle, the old Huguenot bastion in France, the community has continued since its founding to figure in history. Men and women of prominence who were born or lived there include Peter Faneuil, John Jay, Gen. Philip Schuyler, Thomas Paine and Susan B. Anthony. Points of particular interest are Ft. Slocum, an army post offshore, and a farm cottage given to Thomas Paine by the state of New York, where he spent several of his last years. Incorporated as a village in 1858 and a city in 1899, New Rochelle adopted the council-manager form of government in 1932. Pop. (1960) 76,812; for comparative population figures *see* table in NEW YORK: *Population*. (C. B. F.)

NEW ROMNEY, a municipal borough in the Ashford parliamentary division of Kent, Eng., and one of the Cinque Ports (*q.v.*), 18 mi. S.S.E. of Ashford by road, and more than a mile from the sea. Pop. (1961) 2,556. Between the town and the sea has grown Littlestone-on-Sea. New Romney lies on Romney marsh, part of a level extending from Winchelsea in the southwest to Hythe in the northeast, which was within historic times in great part covered by an inlet of the sea. The marsh is cordoned off by the Royal Military canal. The river Rother, which now has its mouth at Rye harbour, formerly entered the sea there, but had its course wholly changed during a great storm in 1287, and the gradual accretion of land led to the decay not only of New Romney but of Winchelsea and Rye as seaports. Romney marsh itself is protected by a sea wall, and its guardianship and drainage are in the hands of a special corporation dating from 1462.

Its harbour was the cause of the early importance of Romney, as it was called before 1562–63, and the annual assembly of the Cinque Ports, called the Brodhull, was held there. At the time of Domesday Book the archbishop of Canterbury and the bishop of Bayeux were joint lords. Romney owed the maritime service to the king of supplying five ships to serve for 15 days in the year. A confirmation of liberties was granted by John in 1205. The town was incorporated by Edward III and was represented in the parliament of 1265. It returned two members from 1366 to 1832. After Elizabeth I's charter of 1563, the town was officially called New Romney. A large collection of records, maps, etc., relating to the Cinque Ports are in the town hall. There is a big sheep fair in August. Of the five churches mentioned in Domesday Book only the Norman church of St. Nicholas remains; there are ruins of a 13th-century priory. The Romney, Hythe and Dymchurch light railway, of 15 in. gauge, incorporated in 1926, is one of the smallest public railways.

NEW ROSS (ROS MHIC TREOIN), a town of County Wexford, Republic of Ireland, on the Barrow, 2 mi. below its junction with the Nore, 87 mi. S.S.W. of Dublin by road. Pop. (1961) 4,494. St. Abban founded the abbey of Rossmactreoin in the 6th century, which gave rise to the ancient city Rossglas or Rossponte. There are remains of a 13th-century Dominican foundation in Rosbercon, on the Kilkenny side of the Barrow which is there crossed by a swing bridge (1869). The Protestant church occupies part of the site of the old Franciscan friary (13th century). In 1269 the town, which stands on a steep hill overlooking the river, was surrounded by walls. The fortresses were dismantled by Oliver Cromwell. Inland water communications reach Dublin by means of the Barrow and the Grand canal. New Ross has breweries and tanyards, a salmon fishery and a fertilizer factory, and exports agricultural produce.

The nearby village of Dunganstown is the ancestral home of John F. Kennedy, who paid a sentimental visit to the family farmstead in June 1963. It was from New Ross that his great-grandfather sailed for the United States in the 1840s.

NEWRY, a seaport, urban district and market town of County Down, N.Ire., is situated on the Clanrye river and Newry canal, 38 mi. S. of Belfast by road. It lies in a valley to the north of Carlingford lough and is within a few miles of the mountains of Mourne. Pop. (1961) 12,450.

The town developed around a Cistercian abbey founded on the left bank of the Clanrye by St. Malachy about the year 1144. The abbey was granted a charter in 1157 by Muirchertach O'Lochlainn, king of Ulster. The name of the town in Irish (Iubhar Cinn Trágha) means "the yew tree at the head of the strand" and it is said that the original yew, the symbol of immortality, was planted by St. Patrick himself. Because of its position in a gap of the hills, Newry has seen much fighting and was set on fire by James II's forces in 1689. St. Patrick's parish church (Church of Ireland), founded in 1578 by Sir Nicholas Bagenal, was the first Protestant church to be built in Ireland, all Protestant churches before that time being existing structures taken over after the Reformation. Newry is the seat of the Roman Catholic bishop of Dromore and the cathedral of SS. Patrick and Colman was completed in 1825. On Trevor hill a private residence, erected in 1775, is a perfectly preserved example of Ulster Georgian architecture.

Newry's industries include the spinning and weaving of linen and cotton, the manufacture of waterproof clothing, the production of mashed-potato powder, and granite quarrying. There are weekly sailings from Newry to Liverpool for freight and livestock.

NEWS AGENCY, an organization that supplies news reports to newspapers, magazines, radio and television stations and other users. It does not publish news itself but supplies news to its subscribers who, by sharing costs, obtain services they could not otherwise afford. All of the mass media depend upon the agencies for the bulk of the news, even including those few that have extensive news-gathering resources of their own.

The news agency has a variety of forms. In some large cities, newspapers and radio and television stations have joined forces to obtain routine coverage of news about the police, courts, government offices and the like. National agencies have extended the area of such coverage by gathering and distributing stock-market quotations, sports results and election reports. A few agencies have extended their service to include worldwide news. The service has grown to include news interpretation, special columns, news photographs and motion-picture film for television news reports.

Many agencies are co-operatives and the trend has been in that direction since World War II. Under this form of organization, individual members provide news from their own circulation areas to an agency pool for general use. In major news centres the national and worldwide agencies have their own reporters to cover important events, and they maintain offices to facilitate distribution of their service.

In addition to general news agencies, several specialized services have developed. In the United States alone these number well over 100, including such major ones as Science service, Religious News service, Jewish Telegraphic agency and Nuclear News service. Specialized services in other countries include the Swiss Katholische Internationale Presseagentur, which reports news of special interest to Catholics, and the Star News agency of Pakistan, which supplies news of Muslim interest in English and Urdu. Several large newspapers syndicate the work of their own correspondents through special agencies such as the New York Times News service, Chicago Daily News service, Chicago Tribune Press service, New York Herald Tribune News service, and the syndicated services of the *Times* and *Daily Express* of London.

The major U.S. press associations have expanded their service to include entertainment features and some feature syndicates provide straight news coverage as a part of their service. The Newspaper Enterprise association (N.E.A.) and the North American Newspaper alliance (N.A.N.A.) distribute both news and features in the United States.

Despite the plethora of news services, most news printed and broadcast throughout the world each day comes from only a few major agencies. A survey of world communications by the United Nations Educational, Scientific and Cultural organization listed more than 80 important news services, but only 5 of them ranked as "world agencies." These five have the financial resources to station experienced reporters in all areas of the world where news develops regularly, to assure them access to well-organized transmission facilities or to send them wherever news develops unexpectedly. These agencies are equipped, also, to distribute the service almost instantaneously. The Associated Press, for instance, estimates it can send a bulletin to 80 countries in less than one minute.

The world agencies have established a variety of relationships with other agencies and with individual news media. Most of them purchase the news services of national or local agencies to supplement news gathered by their own staff representatives at key points. Reuters, the British agency, reports that it is "affiliated with the principal news agency in every country in the world." Reuters, like the Agence France-Presse, supplies a worldwide news file to be distributed by some national agencies along with their domestic news reports. The U.S. services more often contract to deliver their service directly to individual users abroad.

A different relationship exists in the Communist orbit. Each major Communist country has its own national news service. Each news service is officially controlled, usually by the minister of information. The services exchange news reports, some of which come from their own correspondents at key points. Tass, the Soviet news agency, is their principal source of world news. Tass also makes Communist party policy known throughout the orbit, either in the form of a daily *Pravda* editorial or other material forming an important part of its service.

Most countries of the world have one or more national news agencies. Some depend on a common service, such as the Arab News agency, which provides news for a half-dozen states in the middle east. Others are national newspaper co-operatives, such as the Ritzaus bureau of Denmark, founded in 1866, which has a well-developed teleprinter network. A few, like ANSA (Agenzia Nazionale Stampa Associata) of Italy, have expanded coverage abroad in limited degree to supplement their domestic service, but still depend on Reuters and Agence France-Presse for much of their foreign news. The Federal Republic of Germany since 1949 has built up Deutsche-Presse Agentur (D.P.A.), now one of the more important news agencies in Europe, with an extensive exchange with other national services. In Canada the Canadian Press is a co-operative news agency with headquarters in Toronto, Ont.

The oldest and largest news agency operating exclusively in Britain is the Press association (P.A.), founded by provincial newspapers on a co-operative basis in 1868. It began active work on Feb. 5, 1870, when the post office took over the private telegraph companies that had previously supplied the provincial papers with news. For 50 years the P.A. transmitted news by press telegrams but in 1920 it leased private telegraph wires from the post office. The association occupied its new London headquarters building in Fleet street in 1939. From this building it supplies news to all the London daily and Sunday newspapers, provincial papers and trade journals and other periodicals.

Capacity for speed has greatly increased during the 20th century. Radioteleprinters that make possible fast automatic transmission of news messages link all major areas. Picture transmission by radio and high-fidelity wires is well developed. During 1951 the Associated Press began a teletypesetter service—a system of wire delivery of news on punched tape that operates typesetting machines automatically—for its U.S. members and clients. United Press International provides a similar service.

The following paragraphs briefly describe the major news agencies of the world:

Associated Press (A.P.).—This is the oldest and largest of the U.S. news agencies. In May 1848 six New York city dailies joined to finance a telegraphic relay of foreign news brought by ships to Boston, first U.S. port of call for westbound transatlantic ships. In 1856 the service took the name of the New York Associated Press, a mutual, which sold its service to various regional newspaper groups. Pressure from the regional customers forced changes in its control, and in 1892 the modern A.P. was set up under the laws of Illinois. The *Chicago Inter Ocean* brought an antimonopoly suit in 1900, and A.P. moved to New York, where association laws permitted the group to continue its strict control of membership, including blackballing of applicants for membership by existing members. In the early 1940s Marshall Field III, who had established the *Chicago Sun,* fought his exclusion from the A.P. service. Prosecution under the federal antitrust powers ended the A.P.'s restrictive practices.

A.P.'s annual budget, approximately $35,000,000, is the highest in the news agency field. In addition to its regular staff, the U.S. members contribute local and regional news gathered by more than 100,000 newsmen. By the 1960s A.P. had its own staff in news centres throughout the world, with 100 offices in the United States and more than 50 abroad. It operated more than 400,000 mi. of leased wire to carry its reports to 1,760 U.S. newspapers and almost 2,000 radio and television stations. More than 7,000 news outlets in 80 nations received its service. In Aug. 1952 it started use of radioteleprinter receivers to link all of South America directly to the New York city headquarters, and the service was extended to Asia, Europe and Africa. A.P. also operates Associated Press, Ltd., in Great Britain.

United Press International (U.P.I.).—This news agency was formed in May 1958 by a merger of United Press (U.P.) and International News service (I.N.S.). U.P. had been founded in 1907 when E. W. Scripps combined three U.S. regional services under his control to sell news to all newspapers. I.N.S. had been formed in 1909 by William Randolph Hearst to provide news to morning newspapers; later, through merger with other Hearst services in 1928, it provided 'round-the-clock service. The 1958 merger consolidated nearly 2,000 domestic and foreign clients of I.N.S. with the more extensive clientele of U.P.

In the early 1960s U.P.I. served nearly 1,600 newspapers and 2,000 radio stations in the United States and approximately 1,200 newspapers and more than 300 radio stations abroad. These and other clients received news in 48 languages, transmitted over wireless and other commercial communication, and through 465,607 mi. of leased wire in North and South America, Europe and the far east. U.P.I. maintained 221 news and picture bureaus, 98 of them outside the United States. It has developed a variety of special service subsidiaries, among them United Features syndicate and U.P. Movietone News; the latter provides news on film to television stations. Another auxiliary, British United Press, serves papers and broadcasters in the United Kingdom and Canada.

Reuters.—This news agency is owned by the newspapers of the United Kingdom, Australia and New Zealand and is operated "as a trust rather than as an investment" to provide a world news service. It was founded by German-born Paul Julius Reuter (*q.v.*), when he moved to England in 1851. Reuter saw the possibilities of the telegraph for news reporting and built up an organization that maintained correspondents throughout the world. The Reuters agency remained in private hands until 1925 when the Press association (P.A.) acquired major control of it and then gained full control in 1941. P.A. later in 1941 sold half of Reuters to the Newspaper Proprietors' association, representing London newspapers, and in 1947 membership was extended to associations representing the daily newspapers of Australia and New Zealand.

As a co-operative Reuters draws from the provincial news coverage of the P.A., the resources of its London newspaper members and from its Australasian partners. It employs about 200 staff correspondents and hundreds of part-time correspondents abroad, who have access to the news files of agencies with which it exchanges copy. Reuters exchanges the Press association's U.K. report for A.P.'s coverage of U.S. news, but each retains the right to market its world report in the other's territory. About 80 U.S. newspapers and radio and television stations buy Reuters service. Directly or through national news agencies Reuters provides its services to about 110 countries and territories, reaching nearly all the world's 8,000 daily newspapers and hundreds of radio and television stations.

Agence France-Presse (A.F.P.).—This agency is the successor to an earlier French world news agency, Havas, which was founded in 1835 but was suppressed at the time of the German occupation of France in 1940. After the liberation of Paris in Sept. 1944 A.F.P. was set up by a group of newspapermen, including former Havas representatives in London and elsewhere and others who had been active in the underground movement in Paris and Algiers. The French government gave them the assets of Havas, including its Paris building, which became the A.F.P. headquarters.

With the assistance of the French government A.F.P. rebuilt a considerable part of the worldwide service of Havas. It is organized as a commercial but nonprofit agency, and a majority of

its board of directors are representatives of the French press. A.F.P. has established 40 offices at home and more than 70 abroad. In addition to contracts with A.P. and Reuters for exchange of news reports, it sells a domestic French news report to most of the world's news agencies and provides its worldwide report to many of them. Within France it has a leased-wire circuit and distributes news to its foreign clients from Paris through radioteleprinter. A.F.P. also has a photo service and a number of specialized news reports, several concerned with African matters.

Tass (**Telegrafnoye Agentstvo Sovietskogo Soyuza**).—This is the central information agency of the U.S.S.R. and is responsible to the council of ministers. It had its origin in the old Petrograd telegraph agency, which was reorganized in April 1918 as Rosta (Russian telegraph agency). On July 10, 1925, Tass was founded.

In the early 1960s Tass supplied news to 4,400 Soviet newspapers and to all Soviet radio stations; it exchanged news with 25 foreign news agencies and had correspondents in 52 countries. It employed 550 staff correspondents and about 300 part-time reporters in the Soviet Union. Its service to foreign clients is transmitted in Russian, English, French, German and Spanish; transmission inside the Soviet Union is mostly by telegraph. Wireless teletype has, however, been widely used and, since 1962, foreign correspondents in Moscow have transmitted their news through leased teletype.

(C. M. H.)

NEW SIBERIAN ISLANDS (Novosibirskiye Ostrova), an archipelago in the Arctic ocean ranging 30–350 mi. off the northern mainland of the U.S.S.R., in the Yakut Autonomous Soviet Socialist Republic, lies between longitude 135° and 158° E. and latitude 73° and 77° N. It divides the Laptev sea from the East Siberian sea. There are three groups of islands: the Lyakhov Islands (Lyakhovskie Ostrova) in the south, separated from the mainland by Dmitri Laptev strait (Proliv Dmitria Lapteva); the New Siberian Islands proper, also called the Anjou Islands (Ostrova Anzhu), in the centre; and the five small De Long Islands (Ostrova De-Longa) in the northeast. The total land area is about 14,500 sq.mi. The islands are low-lying (greatest elevation 1,050 ft.), and consist of limestones and shales with granite and granodiorite intrusions, largely covered by Quaternary deposits and thick layers of fossil ice. The latter contain animal remains, including mammoth tusks, hunting for which became the islands' main industry. True glaciers are now found only in the De Long Islands. Several deposits of lignite are known. The climate is typically arctic, with a mean July temperature of 3° C. (37° F.), low precipitation, and snow lying for nine months of the year. Vegetation is that of the tundra, and wild life includes reindeer, arctic fox, lemming and rare polar bear. Many birds come to nest in summer. There has never been a native population, but the U.S.S.R. has established hunting stations, where hunters may live all the year round if they wish, and several weather stations.

Cossack explorers, sailing from the Lena and Kolyma rivers in the 17th century, heard stories of, and probably even saw, land to the north, but the first to reach it was Merkuri Vagin, who visited the most southerly island in 1712. Ivan Lyakhov, a Yakutsk merchant, became interested in the prospects of mammoth ivory, and went there in 1770 and 1773–74. He obtained a monopoly of ivory-trading in the area and the two southerly islands were named after him, but he also discovered parts of the central group. Other merchants followed him and made further explorations, notably Yakov Sannikov in 1800 and 1805. Sannikov joined an official exploring expedition in 1809–10 led by M. M. Hedenström (Gedenshtrom), an exiled civil servant from the Baltic states. Sledge parties covered much of the central and southern groups. Hedenström saw open water to the northward, a fact which contributed to the idea, very prevalent later, of an open polar sea. Another expedition, whose object was to improve Hedenström's map, worked successfully in 1821–23 under Lieut. P. F. Anjou. The De Long Islands were discovered in 1881 by the American G. W. De Long, whose ship "Jeanette" was crushed by the ice near them. The next phase of exploration is associated with the Russian geologist E. von Toll, who worked in the group in 1886, 1893, and again in 1901–02, when he lost his life there. These expeditions yielded important scientific results. The Russian ships "Taimyr" and "Vaigach" visited the archipelago in 1912–14 and the Norwegian ship "Maud" in 1924. The Academy of Sciences set up the first scientific station on Bolshoi Lyakhovski Island in 1927–30; since then one or more such stations have been continuously manned and have acted as bases for further exploration.

See I. M. Ivanov, ***Novosibirskiye Ostrova*** (1935). (T. E. A.)

NEW SOUTH WALES, the most populous state of the commonwealth of Australia, was discovered and named by Capt. James Cook in 1770 and settled by Capt. Arthur Phillip in 1788. It consisted originally of all Australian territory east of longitude 135° E. (more than half the continent), but the western boundary was moved to longitude 129° E. in 1825, and thereafter the other eastern states were formed by separating from this area: Tasmania in 1825, South Australia in 1836, Victoria in 1851, Queensland in 1859, the Northern Territory in 1861–63 and the Australian Capital Territory in 1911. Thus the original area of 1,584,389 sq.mi. was reduced to 309,433 sq.mi., or about one-tenth of the continent. The present boundaries are as follows: on the east, the Pacific ocean from Point Danger to Cape Howe; on the west, the 141st meridian of east longitude; on the north, the 29th parallel of south latitude, proceeding east along the Barwon and a spur of the Eastern highlands, and thence along the crest of the McPherson range to the sea; on the south, the southern bank of the Murray river to its source, and thence a straight line to Cape Howe. The coastal boundary, direct from Point Danger to Cape Howe, is 683 mi. long; the western boundary is 340 mi.; and the average breadth between these is about 650 mi. The capital is Sydney.

PHYSICAL GEOGRAPHY

Geology.—The state can be divided into three geological areas: the coastal plains, the tablelands, and the western slopes and plains. The coastal plains consist mainly of post-Tertiary fluviatile deposits. In the north, between the Richmond and Tweed rivers, an area of decomposed basalt is particularly fertile and suitable for intensive agriculture and dairy farming. The coastal area also contains two coal-bearing basins, the more important extending between the Hunter and Shoalhaven rivers. The tablelands of the dividing range are composed largely of Paleozoic sediments together with granite and other igneous rocks. The area west of Sydney, north to Maitland and south to Wollongong, is capped with Mesozoic strata. The western slopes and plains are underlaid with granitic rocks and sediments of the Paleozoic, Mesozoic and Early Tertiary ages. In the south, on the lower Darling and Murray rivers, there is a large area of Early Tertiary marine beds, and in the Riverina underlying granitic, Silurian and Devonian rocks. In the north, Mesozoic (Triassic) strata form part of the Great Artesian basin, bordering southward with a Paleozoic belt that stretches west to the South Australian border. The surface of the plains is generally covered with post-Tertiary deposits and flood loams except where occasional outcroppings of earlier formations rise to the surface.

Physical Features.—The state consists of four natural geographical divisions: the coastal lowlands; the tablelands forming part of the Eastern highlands (*q.v.*) between the coast and the plains; the western slopes of the highlands; and the western plains. The tablelands form a watershed: the coastal division is drained by numerous short, rapid rivers which flow eastward from the plateau to the sea; in the west, the one river system, the Murray-Darling, drains the slopes and plains, entering the sea in South Australia. The Murray river (*q.v.*), rising in the southern highlands, and joined by the Lachlan-Murrumbidgee (watering the southeastern slopes) and the Darling river (*q.v.*) and its tributaries (watering the central north and northwest), is the longest and most important river. The coastal rivers are rain fed and

PHYSICAL FEATURES, CITIES AND TOWNS OF NEW SOUTH WALES, AUSTR.

liable to flood. The western rivers are longer and have larger drainage areas, but they have a less reliable flow and, particularly the Darling and its tributaries, are subject to regular droughts. The lack of water is a continual problem west of the Eastern highlands except in the irrigation area along the Murrumbidgee and the Murray.

The Coastal Lowlands.—These are low lying, undulating, well watered and fertile. Their average width is 50 mi. in the north and 20 mi. in the south, the widest part being the 150 mi. of the Hunter valley. The climate is mild to hot, and humid. The average monthly temperatures vary between 14° and 24° C. (57° and 76° F.) in the north and 11° and 20° C. (51° and 68° F.) in the south. The rainfall ranges between 30 and 80 in. a year and is greater in the north. The coastline consists of a succession of rugged promontories alternating with sandy beaches, inlets, river estuaries and, occasionally, marine and estuarine lakes. The river mouths are usually sand obstructed, but in the central coast subsidence has produced some fine drowned valleys, of which Port Jackson (Sydney) is outstanding. Along the rivers lies fertile alluvial land suitable for intensive agriculture (fodder crops, market gardening, fruit and, in the north, sugarcane) and dairy farming. There are rich coalfields round Newcastle and Wollongong. Almost everywhere the tablelands are separated from the coast by steep and often precipitous escarpments and gorges.

Although less than 35,000 sq.mi. in area, this division has four-fifths of the state's population and most of the factory employees. It contains the capital and the next two largest towns, nearly all the coal and manufacturing areas, all the seaports, the bulk of the dairying and maize (corn) growing, and the state's governmental, financial and commercial headquarters. Wheat and sheep, however, are virtually excluded from this division because of the damp climate. The most heavily populated areas are Sydney, the Hunter valley, the Clarence-Richmond-Tweed basins and the Illawarra district.

The Tablelands.—These form an extensive and almost unbroken belt of plateaus running roughly parallel with the coast, varying in width from 30 to 100 mi., averaging 2,500 ft. in height and rising to 4,877 ft. in the north (Ben Lomond), about 3,400 ft. in the centre (Blackheath) and 7,316 ft. at Mt. Kosciusko (Australia's highest peak) in the south; the average height of the northern plateau exceeds that of the southern. To the east the tablelands fall steeply to the coast; to the west they slope gradually to the plains. The climate is cool or cold, with uniform and reliable rainfall. The average monthly temperatures are 7°–21° C. (45°–70° F.) in the north and 3°–17° C. (38°–63° F.) in the south—about 5° C. (10° F.) lower on the average than in the corresponding coastal regions. The average annual rainfall varies from 40 in. in the east to 30 in. in the west.

Although there is good agricultural land on the tablelands, much of the country is too rough for anything but grazing sheep and cattle. There are, however, important mineral resources: tin in the north, coal in the centre (around Lithgow) and gold in both north and south. Lithgow is the only large manufacturing town, and most other towns are commercial centres for pastoral, agricultural and mining activities. The Blue mountains, due west of Sydney, are a convenient and popular tourist resort. The tablelands account for only 13% of the area of New South Wales, and less than one-tenth of the state's population lives there. Agriculture consists mainly of mixed farming, particularly a combination of sheep (nearly one-quarter of the state's total) and/or cattle and crops.

The Western Slopes.—To the west the tablelands slope gradually to the great western plains. The slopes, varying from 150 to 300 mi. in width, consist of gently rolling country that descends from the plateaus (at elevations above 2,000 ft.) to levels of less than 1,000 ft. on the plains. The climate is warm and dry, with a uniform rainfall. Average monthly temperatures are 23°–27° C. (73°–81° F.) in summer and 8°–12° C. (46°–53° F.) in winter. The average annual rainfall varies from 30 in. in the east to 20 in. in the west.

This division, with an ample and fairly reliable rainfall and fertile soil, is devoted mainly to mixed farming, particularly the production of wool and wheat, the state's best wheat-growing area being the southern slopes. In this area, also, the upper basins of the western rivers and streams and the outcrops of ancient rocks along the slopes in the past yielded rich minerals, particularly gold. The western slopes, with only 14% of the state's area and one-twelfth of the population, account for half the wheat crop and nearly one-third of the sheep. Tamworth is the largest town.

The Plains.—Covering nearly two-thirds of New South Wales, the plains extend from the edge of the slopes to the state's western boundary, being interrupted only by the elevated country from Orange to Cobar, and the Grey and Main Barrier ranges in the far west. They can be divided into the central plains and the western plains. The central plains consist of the Riverina (*q.v.*) district, divided from the western plains by the Lachlan and Murrumbidgee rivers (*qq.v.*), and the low flatlands stretching east of the Barwon and Bogan rivers. The western plains consist of the area west of the Lachlan, Bogan and Barwon rivers. Both plains, substantially the large flat basins of the Murray-Darling system, are floored with generally fertile red and black soils but receive a scanty rainfall. However, the northwestern plains fall substantially within the Great Artesian basin, and the southwestern plains in the Murray river artesian basin. Moreover, the dams on the upper courses of the Murray, Lachlan and Murrumbidgee have greatly increased the agricultural possibilities of the Riverina by irrigation. The Snowy mountains hydroelectric scheme has diverted many streams and rivers from their original eastward courses, so that water that was originally lost to agriculture is now available for irrigation in the Murray basin. (*See* AUSTRALIA, COMMONWEALTH OF: *The Economy: Production: Power;* and AUSTRALIAN ALPS.) The climate is warm to hot, and dry, with a coolish winter. The average monthly temperatures are 24°–29° C. (75°–84° F.) in summer and 9°–12° C. (49°–54° F.) in winter. The average annual rainfall varies from 7 in. in the northwest to 10–15 in. along the Darling and 20 in. in the east.

In the western plains pastoral and mining activities alone have significance. Silver, lead and zinc are mined at Broken Hill, and opals at Lightning Ridge. Pastoral holdings are large, and towns well spaced and, except Broken Hill, small. In the central plains, while wool and wheat predominate throughout, farming is relatively less important in the north and more important, especially in the irrigation area, in the south. The division accounts for two-fifths of the state's land but has only one-twentieth of the population (mostly in the central plains). It has two-fifths of the sheep (largely in the centre) and contributes similar proportions of the wheat crop (in the centre) and of the mineral production (from Broken Hill in the west).

Climate.—New South Wales is situated entirely in the temperate zone, and its climate is generally mild, although occasional

high temperatures are experienced in the northwest and some extreme cold on the southern tablelands. There is abundant sunshine in all seasons. Average temperatures are higher by 3°–4° C. (5°–7° F.) in the north than in the south, and the mean daily range increases from 9° C. (19° F.) on the coast to about 14° C. (26° F.) on the western plains. Most of the state has frosts for up to five months of the year, but these are severe only on the tablelands and western slopes. Snow is rare except on the tablelands; perennial snow is found only on the highest peaks in the south. The seasons are well defined, autumn beginning in March, winter in June, spring in September and summer in December. The weather is determined chiefly by anticyclones that pass almost continually across the state from west to east, with consequent tropical and antarctic depressions; the state is fairly free from cyclonic disturbances. In summer the prevailing winds on the coast are northeasterly; in the west they are variable, with a marked northerly component in the north and a pronounced southerly component in the south. In that season the prevailing direction of the wind is westerly in the southern and southerly in the northern part of the state. In winter New South Wales lies directly in the great high-pressure belt. Rainfall varies from an average 80 in. a year in the northeast to less than 7 in. in the northwest; generally, the east receives more rain, and more uniformly, than the interior. The rate of evaporation increases from about 40 in. a year on the coast to about 100 in. in the northwest. Heavy rains cause extensive flooding of the rivers, especially on the coast; and droughts, particularly in the interior, are also common. The winter rain region is bounded on the north by a line from Broken Hill to Wagga Wagga with a curve round to Albury, *i.e.*, the southwestern corner of the state; the summer rain region lies north of a line from the northwestern corner to Newcastle; between those regions the rainfall is fairly evenly distributed, except on a narrow southern coastal strip between Nowra and Broken bay, which receives its heaviest rain in autumn. Winter rains arise from antarctic, summer rains from tropical, depressions. Rainfall has exerted a powerful influence in determining the character of rural settlement, the intensity of which varies directly with the amount and certainty of the rain.

Vegetation.—Of the 9,000 botanical specimens found in Australia, about 3,600 are to be found in New South Wales. The natural vegetation is very varied, from the dense semitropical forest of the north coast to the sparse vegetation of the western plains. Except for the plains, the state is well wooded, nearly one-tenth of it being covered with forest and a much larger area with bush and scrub. The forest land is concentrated mainly on the coast and tablelands, giving way on the western slopes to shrub eucalypts, and in the far west to saltbush and spinifex. The predominant tree is the eucalyptus, which has a great variety of species and is the main source of the state's hardwood; it grows quickly and yields well, and its better varieties, *e.g.*, ironbark and tallowwood, provide excellent timber. The eucalypti are specialized in habitat: the ironbark is found mostly on the coast and warmer parts of the tablelands; the tallowwood on the north coast; the Murray red gum, though ubiquitous in Australia, in forests along the western rivers; and less valuable varieties (the box, the stringybark and the turpentine) on the coast and tablelands. The softwoods are found in much smaller quantities on the north coast (the red cedar, the colonial or hoop pine and rosewood) and on the western slopes (the cypress pine) and are used extensively as cabinet timbers. Native grasses cover most of the state except in the far west and where overstocking has been severe. Many varieties are drought resistant and good fodder and partly explain the excellence of the New South Wales pastures for sheep rearing.

Animal Life.—The fauna of New South Wales is rich in marsupials and birds. The dingo was once fairly common in western New South Wales, where it preyed on sheep, but fencing and hunting have made it rare. Of Australian marsupials, New South Wales has three of the four species of native cat, one species of wombat, the native bear or koala, the common and ring-tailed opossums, the common and long-nosed bandicoots, and a variety of kangaroos and wallabies. The platypus and echidna are both found. Bird life includes the emu in the west; of the mound builders, both the scrub turkey and the mallee bird; the lyrebird on the north coast; a host of parrots and other more common species. Snakes, particularly the black snake, are also found over most of the state. The best-known fish is the Murray cod, an excellent table fish, which is found in all the western rivers.

Both flora and fauna have been considerably modified by European settlement. Reforestation, particularly with softwoods, is changing the pattern of forests; introduced grasses and intensive agriculture are changing the character of pastures in many areas; and, generally, all animal life is retreating to the less inhabited regions of the state. Some immigrants, *e.g.*, the rabbit and the trout, are completely acclimatized (*see* also NATURALIZATION, PLANT AND ANIMAL).

HISTORY

The early history of New South Wales, from its settlement with convicts under Capt. Arthur Phillip in 1788, is one with the early history of the British period in Australia. For this period especially, until the end of Lachlan Macquarie's governorship in 1821, *see* AUSTRALIA: *History*.

Pastoral Expansion and Self-Government, 1822–55.—In these years the foundations of modern New South Wales were securely laid. Self-government was attained; radicalism emerged; voluntarism was established as the basis of colonial religion; transportation of convicts ceased; trial by jury and a free press were allowed; and the rapid expansion of the pastoral industry made the colony prosperous. New South Wales changed from a prison farm into a self-governing colony with a free and expanding economy. The basis of the expansion was wool. Exploration in the 1820s and 1830s opened up the whole of the colony, and the increasing demand for wool in Yorkshire enabled the squatter pastoralists to avail themselves of the new land, which provided excellent pastures for the fine-wooled Merino. Wool was a source of sterling funds and an inducement for capital imports and immigration. The consequent wealth was a solvent of autocracy. The growing body of free settlers was not prepared to suffer autocratic government and transportation, which lowered the moral tone of the colony. But the impetus for colonial reform came also from Britain.

Thus, acts of 1823 and 1828 gave New South Wales a nominated legislative council; an act of 1842 made this partly representative; and the Australian Constitutions act, 1850, made it completely representative with the powers of writing a constitution. Nevertheless, until 1855 executive control rested entirely with the governor and his executive council, consisting of officials. The legislative council was dominated by the pastoralists, who tried to frame a constitution to thwart the democratic aspirations of the city and labour interests; but the bicameral legislature finally adopted avoided the autocratic ambitions of the pastoralists and was the future source of much liberal legislation.

The most important social conflict between 1822 and 1855 concerned the status of the former convicts, but, after transportation was discontinued in 1840, wealthy emancipists and exclusives were brought into an alliance to fight for self-government and against the colony's growing radical movement. In religion the privileged status of the Church of England was modified, and the various Christian denominations demanded and received legal equality. The attempt by Gov. Sir Richard Bourke to introduce public secular education foundered on the opposition of the churches. But the most important political conflict concerned the alienation of land. The squatters had settled on land beyond "the limits of location" (a defined small area, to prevent undue dispersion and make government easier) and until 1847 had the most temporary titles to their estates. Gov. Sir George Gipps tried to prevent the complete alienation of the state's pasturelands but was unable to prevent the 1847 orders-in-council which gave the squatters favourable treatment. The quarrel over land, however, continued throughout the 19th century.

Colonial Liberalism, 1856–85.—In Feb. 1851 gold had been discovered near Bathurst, but the main tide of the gold rushes soon swung to the richer fields of Victoria. New South Wales

nevertheless gained in wealth and population from gold. In 1856 the new constitution was implemented with a bicameral legislature and responsible cabinet government. One of its early acts in 1858 introduced the ballot and universal adult male suffrage, and the new democracy soon moved against the squatters. "Radical" legislation in the next 30 years included the abolition of state aid to religion (1862), the Triennial Parliaments act (1874), the Public Instruction (public schools) act (1880) and public health legislation (1881). Sir John Robertson's land act of 1861 aimed at facilitating closer settlement by allowing selection before survey; anyone might select from 40 to 320 ac. within the "settled" or "intermediate" districts on payment of a quarter of the price, the balance being due, with the title, after three years' residence. Some genuine closer settlement resulted, especially on the coast, but the squatters' devices of "peacocking" and dummying, *i.e.*, picking the best land and using dummy selectors, left most of the western lands in their hands. The failure to settle much of the increasing population on the land meant greater concentration in the towns, besides the rapid growth of trade unionism and radicalism among the growing body of workers. Radicalism before 1870 was reflected in the land legislation and opposition to the British government. Between 1870 and 1885 it encouraged state intervention in social and economic life and increased the political aspirations of the trade unionists. Sir Henry Parkes (*q.v.*) was the most influential personality in politics, and between 1872 and 1891 his ministries introduced free trade, established nonsectarian public schools and sponsored railway development. He finally lost office because he favoured federation before the idea was popular in New South Wales.

This was a period of great economic development. By 1890 New South Wales was self supporting in foodstuffs; valuable minerals had been discovered and mined—gold at Captain's Flat in 1861, copper at Cobar in 1869, tin at Inverell in 1871 and silver-lead-zinc at Broken Hill in 1883; 1,215 mi. of railway were completed by 1884; unassisted immigration between 1873 and 1893 exceeded 230,000. These developments were greatly helped by the capital imports of the 1870s and 1880s, many of them by the government for public works.

Labour, Nationalism and Federation, 1886–1914.—This period was dominated by growing nationalism, the rise of the political labour movement and the federation of the Australian colonies into the commonwealth of Australia. The period began with the collapse of export prices and the great reduction of capital imports consequent on British financial difficulties. This led to wage reductions, industrial unrest, the great strikes of 1890–91 (in which the trade unions were defeated) and the financial crisis of 1892. Although a time of misfortune, culminating in the big drought of 1902–03, the 1890s were crucial in New South Wales' history. The *Sydney Bulletin*, a radical weekly, encouraged a nationalist literature, which included distinguished contributions from Henry Lawson, Joseph Furphy and many others. The failure of direct action in the 1890 strike forced the unions into politics with immediate influence on legislation. G. H. Reid, with Labor party support, introduced financial reforms (including income tax), removed the public service from political control, reformed the land law to allow the breakup of large estates and passed the Factories and Shops act (1896). Similarly, after 1900, liberal legislation supported by Labor introduced old-age pensions (1900), compulsory industrial arbitration (1901), women's franchise (1902) and free public education (1906). After federation Labor gradually increased its power until in 1910 J. S. T. McGowen was able to form the first Labor ministry. Undoubtedly the protection that came with federation favoured the development of New South Wales as the centre of Australian heavy industry and thus of the industrial proletariat and the Labor party. But a similar development also occurred in agriculture, where, between 1900 and 1914, the area of cultivation doubled, with a rapid increase in the production of wheat, fruit and dairy products. In 1912, also, the Riverina was opened up for closer settlement.

Boom and Depression, the 1920s and 1930s.—At the beginning of World War I, New South Wales had a Labor ministry under W. A. Holman, but his support of conscription led to his expulsion from the Labor party and his formation of a National ministry in 1916. Labor was returned to office in 1920, and Labor and Nationalist ministries alternated until the depression discredited Labor and put the Nationalists in office for a decade. The failure of Labor after its promising beginning was due mainly to its loss of both social purpose and emphasis on social experimentation, and to internal dissension. The 1920s were a period of boom, with considerable immigration and capital imports, and the expansion of public works, *e.g.*, railway building and the Sydney harbour bridge, and private industry. In the world depression after 1929, however, New South Wales suffered badly, with declining export income, the cessation of capital imports and high unemployment (one-quarter of the total male work force in 1933). Recovery was slow and not complete by 1939. John T. Lang, Labor premier in 1925–27 and 1930–32, is one of the most controversial figures in the history of the Australian Labor movement. He introduced some important social legislation, *e.g.*, widows' pensions, but was dismissed from office by the governor in 1932 for repudiating overseas debt payments after his government had legally committed itself, by agreement with the commonwealth, to paying them. In a landslide victory the Nationalists under B. S. B. Stevens were returned in 1932 and retained office until 1941. By then, however, Lang had been expelled from the party, and Labor had regained its unity of purpose.

World War II and Postwar Industrial Expansion.—Labor governments were returned throughout World War II and up to 1962, with W. J. McKell, J. McGirr, J. J. Cahill and R. J. Heffron as premiers. The only notable social legislation in this period was that for the 40-hour week (1947) and compulsory trade unionism for all wage earners (1954). After 1940, however, under the stimulus of war, the postwar boom and substantial immigration, New South Wales experienced the greatest industrial expansion in its history (see *The Economy*, below).

POPULATION

The population of New South Wales increased from 1,024 in 1788 to 3,917,013 in 1961 (37% of the Australian total), the population at intervening dates being 197,265 in 1851, 1,701,736 in 1911 and 2,984,838 in 1947. Until 1860 immigration was more important than natural increase in the growth of population; afterward the reverse was true. The important periods of immigration were 1830–40, 1850–60 (the gold rushes), 1861–85, 1911–14, 1924–28 and after 1948; net immigration between 1949 and 1961 was 369,649. But in the hundred years from 1861 net immigration was less than one-quarter of the total population increase. The crude birth rate fell between 1864 and 1903, improved until 1913, declined to a record low level in 1934 and then slowly increased. The net reproduction rate followed a similar pattern, and in the mid-1950s it was still greater than unity (1.396) and higher than that of most European countries. The infant mortality rate declined from 124 in 1881–85 to 21 in the early 1960s, and the average expectation of life increased from 47 to 70 during the same period. The sex distribution in the early 1960s was 101 males to 100 females (in 1911 the ratio had been 109:100); and the proportion of adults grew steadily from 1881.

There has always been a high degree of urbanization. Sydney increased its population from 95,789 (27.3% of the state total) in 1861 to 1,484,004 (49.7%) in 1947; in 1961 Sydney had 2,183,388 persons and the remainder of the state 1,733,625. The other large centres are Newcastle (208,630 in 1961), Wollongong (131,754) and Broken Hill (31,267); these, with Sydney, contain about two-thirds of the state's population. The drift toward the central coast caused concern, but little action was taken to reverse the trend. Between 1911 and 1961 total population increased by 138% and urban population by 358% (Sydney, 226%), while rural population decreased by 29%.

ADMINISTRATION AND SOCIAL CONDITIONS

New South Wales has its own constitution, conferred by imperial statute in 1855, and its own governor and legislature. Although still nominally subordinate to the parliament of the United

Kingdom, the parliament of New South Wales may for all practical purposes legislate in all matters not specifically reserved to the national (commonwealth) government. The governor is the crown representative in the state and the titular head of the government. The state legislature consists of the legislative council and the legislative assembly, and its enactments are restricted only by imperial legislation still applying to New South Wales and by commonwealth legislation validly applicable to the state. The legislative council consists of 60 members, 15 of whom are elected triennially by the two houses sitting together. The legislative assembly, the popular house, consists of 94 members elected triennially by adult suffrage. Compulsory voting was introduced in 1930. All money bills must originate in the legislative assembly, which, by its power over supply, controls the executive. The cabinet consists, by convention, of members of parliament of either house who have been chosen to administer departments of state.

In the early 1960s there were 15 main ministerial departments—the treasury, education, the attorney general, housing and co-operative societies, justice, the chief secretary, health, agriculture and conservation, labour and industry, transport, mines, land, social welfare, local government and highways, and works. There are also various important public services administered by statutory commissions, boards or trusts, concerned with such matters as fire fighting, main roads, railways, police, electricity, forestry, government insurance, ports and harbours, hospitals and housing. These, too, are subject to considerable ministerial control.

New South Wales is represented in the commonwealth parliament by 10 members in the senate (out of a total of 60) and 45 (of 122) in the house of representatives.

Education.—In New South Wales education is provided for by a system of public primary and secondary schools and technical colleges, by private schools and by three independent universities, which are, nevertheless, largely dependent on state finance. The University of Sydney, founded 1850, is Australia's oldest university; the University of New England, founded 1954, at Armidale, originally was the New England University college branch (1938) of the University of Sydney; and the University of New South Wales, founded 1958, at Kensington, grew out of the New South Wales University of Technology (1949). The private schools, which receive no public money, are largely Roman Catholic, although there are also large independent Protestant schools in Sydney.

Health and Welfare.—The health of the community is provided for largely by a private medical profession, a system of public hospitals and a government department of public health. This department supervises the work of local authorities in implementing acts concerned with health, and also the state hospitals, maternal and baby welfare services, and school medical and dental services. Roughly one-third of the cost of the hospitals was met from fees in the early 1960s.

Since World War II there has been little unemployment in New South Wales, although figures of more than 50,000 were recorded in 1957–58, 1958–59, 1960–61 and 1961–62. Both money and real wages have risen slowly but steadily; average weekly earnings in the early 1960s exceeded £A24.

THE ECONOMY

New South Wales is, economically, the most important state in Australia. Of total Australian personal incomes, it contributes about two-fifths. In the 1960s the state contained nearly half the sheep, one-quarter of the cattle and nearly one-third of the pigs of Australia. It produced two-fifths of the wool, one-fifth of the butter, nearly one-third of the bacon and ham, one-third of the wheat, one-quarter of the oats, more than one-third of the maize (corn) and all the rice. It mined three-quarters of the black coal of Australia and accounted for more than two-fifths of the value of factory production.

At the foundation of the colony in 1788 all land was vested in the British crown, but alienation was allowed, by grants up to 1830, and thereafter by sale and lease. By the 1960s, of the total area of New South Wales, nearly one-third was alienated land or land in process of alienation, three-fifths was leased crown land (mostly long term or perpetual) and the rest was land reserved to the crown.

Agriculture.—The pastoral industry was the basis of the expansion of the colony after 1820, and it is still statewide; the far west is devoted entirely to it. In the central west (including the Riverina), where the annual rainfall is 15–20 in., there is widespread mixed farming. The remainder of the state has large areas of agriculture. The density of settlement and of agriculture increases from west to east. On the tablelands and coast, intensive farming and dairying on compact holdings, with grazing on rugged backlands, are characteristic.

In the 1960s there were about 75,000 holdings larger than one acre, many of which were devoted to mixed farming. Most of them grew crops; nearly one-fifth were registered dairies; nearly one-third carried at least 20 beef cattle; about half had 50 or more sheep; and one-fifth carried pigs. Of the land under crops, about half is devoted to wheat, one-fifth to green fodder, and one-tenth each to oats and hay. Other crops are maize (corn), rice, potatoes, grapes and sugarcane.

Sheep rearing is the main rural industry. Up to 1900 the cultivation of crops barely met local needs, but wheat growing expanded rapidly after 1897, and, with new varieties (bred by William Farrer), closer settlement and the irrigation of the southwest, wheat became an important export crop second only to wool. The total area under crops thus increased from about 1,050,000 ac. in 1891–95 to a record peak of 7,150,000 ac. in 1948 (nearly one-quarter of the area suitable for cultivation).

However, nearly one-tenth of the land is still held for grazing, and the pastoral industry provides about two-fifths of the total value of primary production. Although sheep are the most valuable, cattle for slaughter and dairying are important on the coast and tablelands. Sheep are most numerous on the western slopes and central western plains. Of about 70,000,000 sheep in the early 1960s, roughly 50,000,000 were Merino. There were about 200,000 horses, more than 4,000,000 cattle and less than 500,000 pigs. The gross value of rural products increased from less than £A50,000,000 early in the 20th century to nearly £A400,000,000 in the mid-1950s (of which half was the value of the wool clip), but it declined afterward.

In the period 1918–39 the rural industries of New South Wales were faced with low home prices and unfavourable terms of trade for agricultural produce in the world markets. But World War II and the postwar boom (1946–51) boosted farm income with record prices and, in the case of wheat, record yields. Wheat prices increased sixfold between 1938–39 and 1947–48, and in 1951 wool prices reached a record level, ten times higher than in 1935–36, although they fell back afterward.

Forestry.—New South Wales is the most important timber-producing state of Australia, with an estimated area of forest reserves of 9,500,000 ac. The Forestry commission treats and places under intensive management at least 30,000 ac. of native forests annually in order to increase their yield of useful timber and also plants about 6,000 ac. of fast-growing pine trees every year. In the 1960s softwood plantations totaled more than 100,000 ac., and the total output of hardwood and softwood accounted for about one-quarter of Australian production. Included in the state forests are about 800,000 ac. of national parks, in addition to the 1,500,000 ac. of the Kosciusko State park.

Fisheries.—Prior to 1959 the bulk of fish caught consisted of mullet, shark and Australian salmon, in that order of importance, but since then tuna fishing, almost entirely for canning, has jumped to second place. In the 1960s the state accounted for about one-third of the boats employed in fishing in Australia and three-eighths of total Australian production; it provided almost all the oysters consumed in Australia.

Mining.—New South Wales contains extensive mineral deposits of great value and variety, of which coal is now the most important; it was discovered at Newcastle in 1797. By the 1960s, of total mining employment (exceeding 20,000) coal accounted for three-fifths and silver-lead-zinc for all the rest except for a few employed in the mining of gold and tin. The most important coal

fields are in the Hunter valley above Newcastle, round Wollongong and at Lithgow; two-thirds of the production comes from the northern field. The production of silver-lead-zinc is dominated by Broken Hill which has a massive deposit of rich ore; smaller quantities are found at Captains Flat. Most of the Broken Hill ore is sent (as ores or concentrates) for treatment in other parts of the commonwealth (mainly South Australia) or overseas. Between 1851 and 1951 gold, mainly from the Bathurst area, totaled more than £A75,000,000, of which two-thirds was mined before 1900, but it now amounts to less than £A300,000 annually. Copper is mined chiefly near Cobar, and tin in the central and northern tablelands.

Power.—The Electricity Commission of New South Wales is responsible for the generation and distribution of electricity, which is sold to local authorities, government railways and tramways, and to some large industrial users. In the 1960s the trend was toward large, centralized power stations supplying big areas through interconnected transmission grids. More than nine-tenths of electricity is generated by thermal power stations, and even after the completion of the Snowy mountains hydroelectric schemes less than one-sixth will be derived from water power. Since World War II there has been extensive electrification of rural areas.

Manufacturing Industries.—The manufacturing industries of New South Wales are located mainly in Sydney, where two-thirds of the factories are situated, with three-quarters of the factory employees. The only other important industrial centres are Newcastle, Wollongong, Lithgow and Broken Hill. Before 1900 manufactures consisted mainly of consumer and durable-consumer goods for local use, such as food, furniture and bricks, but federation brought both the removal of interstate trade barriers and a protective tariff for the whole of Australia. This fostered steady industrial expansion, which, although temporarily curtailed by the 1929–33 depression, was greatly stimulated by World Wars I and II. The most remarkable advance was in the manufacture of iron and steel and metal goods, which by the early 1960s employed more than 200,000 persons. Other important industrial fields are: textiles and clothing; food, drink and tobacco; chemicals and paints; and paper and printing. The period of greatest industrial development was after 1938, factory employment roughly doubling by the early 1960s. There are many small factories and relatively few large ones. Nevertheless, although three-quarters of the factories employ 10 or fewer workers each, and fewer than 3% employ more than 100 each, these large factories account for half the total number of employees. Some concerns, such as the Broken Hill Proprietary Co., Ltd. (iron and steel) and Australian Consolidated industry (glass), dominate whole industries.

Trade.—New South Wales has a large overseas and interstate trade. It accounts for about one-third of Australia's exports and, because Sydney is the port of entry for a large quantity of goods destined for other states, more than two-fifths of the imports. Exports consist largely of primary produce, but the proportion of manufactures and semimanufactures, especially to Asia, has been increasing since World War II. Imports consist mainly of machinery, metals and metal manufactures; yarn, textiles and clothing; petroleum; paper; tea; and tobacco. The main destinations of exports are the United Kingdom (although relatively a much smaller customer than before the war), other western European countries, other commonwealth countries, Japan and the United States. The United Kingdom is still very important as a supplier of imports, other suppliers being the United States and other commonwealth and European countries.

The interstate trade of New South Wales consists mainly of the import of large quantities of foodstuffs (sugar, salt, potatoes, fruit), minerals (from South Australia and Tasmania) and timber; and the export of iron, steel, cement and metal goods (mainly to Western Australia and Tasmania) and coal (to all states except Queensland).

Public Finance.—The revenue of the government (excluding income from the state-owned railways, tramways and buses, and Sydney harbour, which is self liquidating) comes partly from state taxation but mainly from the commonwealth government (chiefly from a tax reimbursement grant whereby the commonwealth collects income tax and redistributes it to the states). The most important state taxes are probate and stamp duties and the land tax, other sources of taxation being liquor licences and racing and betting. The chief items of expenditure, in order of importance, are: education; public health and recreation; law and order; and general administration.

Transport and Communications.—New South Wales is well served by rail, road and air services. The outstanding features of communications after World War II were the growth of motor transport for goods, and of air transport for passengers, and the rapid increase of television viewers after the service started in 1956. The state-owned railway lines are centred on Sydney and so distributed that most towns have reasonable access to rail transport. More than two-thirds of the roads are surfaced, and registered motor vehicles include one private car for every six persons. Air services within New South Wales, which include links between all the main towns, are provided by Trans-Australia Airlines and a small number of privately operated lines. The chief ports are Sydney, Newcastle, Port Kembla, Botany bay (for oil), Coff's harbour and Twofold bay (for timber) and the Clarence river (for sugar and timber). Since 1936 all ports have been administered by the Maritime Services Board of New South Wales, the state also being responsible for the construction, maintenance and dredging of all ports except Sydney. The Australian National line, operated by the Australian Coastal Shipping commission, is particularly important for New South Wales in supplying bulk ore carriers and a shipping service to Tasmania.

In the early 1960s there were 17 national and 37 commercial radio stations in the state. By the beginning of the decade there were one operating and five planned national television stations, together with two operating and four planned commercial stations.

NEWSPAPER. Some idea of the magnitude of the modern newspaper industry may be gathered from the fact that when in 1961 the United Nations Educational, Scientific and Cultural organization (UNESCO) published the results of an exhaustive investigation it reached the conclusion that not less than 8,000 daily newspapers were produced throughout the world. It stressed the fact that this must be regarded as the lowest rather than the highest figure because there were some parts of the world from which it was not possible to collect full details. There were 40 countries and territories in which no daily journal was published at all. The number of copies printed daily was at least 290,000,000, of which about 99,000,000 were printed in the English language in 2,350 publications in 70 countries. The country in which the daily press had the largest circulation was the U.S., with 58,000,000 copies or 20% of the world total, and the country with the highest daily newspaper circulation per 1,000 inhabitants was the United Kingdom, with 582 copies compared with the world daily circulation of 100 for every 1,000 inhabitants.

Newspapers themselves are a modern development; some of their functions have in the past been performed by a variety of means. There were writers of newsletters in ancient Rome who furnished news to those who resided at a distance from the capital, and written newsletters continued to be employed to supply intelligence to businessmen and political leaders until long after the invention of printing (*q.v.*). Indeed they have their modern counterparts in the "confidential newsletters" supplied to businessmen and others. In the consulship of Julius Caesar the *acta diurna* bulletins devoted chiefly to government announcements, came to be posted daily in public places in Rome (*see* also ACTA). Other forerunners of printed newspapers were the town criers (or bellmen), posted proclamations, controversial pamphlets, ballads, broadsides and news pamphlets. Many of the last named appeared in Germany and other European countries in the 16th century and were sold at fairs and in shops; they usually dealt with a battle, a disaster, a marvel or a coronation. In the first two decades of the 17th century, more or less regular papers printed from movable type sprang up in Germany, Austria, the Netherlands and Italy.

This article is divided into the following sections:

I. UNITED STATES

Although printing presses were established at Cambridge, Massachusetts Bay Colony, in 1638, at nearby Boston in 1674 and at Philadelphia in 1685, nothing that could properly be called a newspaper was published in the American colonies until Benjamin Harris issued his *Publick Occurrences Both Forreign and Domestick* in 1690. Free speech and free printing had no legal standing in the colonies in the 17th century. Royal charters commonly contained provisions for licensing the press, but the governors regarded printing as dangerous. Packets of newspapers were brought over from England, and at least two issues of the *London Gazette* were reprinted in the colonies. A few professional newsletter writers did some business, and private letters of news were passed from hand to hand. Ballads, proclamations and pamphlets contained some news. In 1689 Massachusetts leaders compiled and published a news broadside entitled *The Present State of New-English Affairs* in order "to Prevent False Reports" and to tell of Increase Mather's efforts in behalf of a new charter following the overthrow of Gov. Sir Edmund Andros.

1. First Newspapers.—The next year Benjamin Harris, London bookseller and publisher who had fled England after imprisonment for printing a seditious pamphlet, issued in Boston no. 1 of *Publick Occurrences Both Forreign and Domestick*, to be "furnished once a moneth (or if any Glut of Occurrences happen, oftener)," on Sept. 25, 1690. Four days later the governor and council suppressed it. This first American newspaper, which was thus ended summarily with its first number, was a very newsy three-page paper (the fourth page being left blank for private correspondence), measuring 6 in. by 9½ in. when folded.

Fourteen years passed before the next venture in American newspaper publishing. In 1704 John Campbell, newsletter writer, bookseller and postmaster, established the *Boston News-Letter*, the first continuously published American newspaper, and issued it "By Authority" for 15 years. Thereafter it was published until the Revolution; then, a Tory paper, it suspended shortly before the British evacuation of Boston. In 1719 William Brooker was appointed postmaster at Boston, and since Campbell refused to turn over the *News-Letter* to him, he founded the *Boston Gazette*. This paper had a long and influential career; during the struggle for independence it was edited by Benjamin Edes and John Gill, called "trumpeters of sedition" by their Tory enemies. It sur-

vived the Revolution but perished in 1798.

First printer of the *Gazette* was James Franklin, who had as apprentice his 13-year-old brother Benjamin. When Brooker lost both post office and newspaper in 1721, and the new proprietor took the printing of the *Gazette* to another shop, Franklin started a new paper called the *New-England Courant.* During its five and one-half lively years, the *Courant* was a spectacular sheet, first as an opposition organ critical of the Mather regime, and later, after the council had banned James Franklin as publisher, as a repository of periodical essays. To evade the council's order, James put his brother Benjamin in as nominal publisher. The latter had already written his first satirical essays, the early "Dogood Papers," for the *Courant;* but his brother treated him badly, and he soon ran away to Philadelphia.

2. Early Papers in Philadelphia and New York.—The *American Weekly Mercury* narrowly missed being the third American newspaper; its first issue, Dec. 22, 1719, was only one day later than that of the *Boston Gazette.* It was founded by Andrew Bradford, son of the William Bradford who introduced printing into Pennsylvania but who by this time had moved his press to New York. The second Philadelphia newspaper was begun by Samuel Keimer with the extraordinary title, *The Universal Instructor in All Arts and Sciences, and Pennsylvania Gazette,* in 1728. The first part of the title was due to the project of Keimer, a scientific deist and an eccentric, to print Ephraim Chambers' *Cyclopaedia* serially in his paper. Benjamin Franklin, now established as a printer in Philadelphia, helped to give the rival *Mercury* a competitive advantage in the town by writing his "Busy-Body Papers" for it, and in 1729 bought Keimer out. He abandoned the cyclopaedic serial, cut off the grandiloquent prefix of the paper's title and made such a success of the *Pennsylvania Gazette* that he was able to retire with a competency at 42. He completely disposed of the *Gazette* in 1766 to his partner David Hall who, with his sons and grandsons and various partners, conducted it until its end in 1815.

Meantime, William Bradford had founded the first New York newspaper in 1725 under the title *New-York Gazette.* It was definitely an organ of government in that colony, and when the bitter contest between Gov. William Cosby and the popular party developed in 1733, John Peter Zenger was induced to start an opposition paper. His paper, the *New-York Weekly Journal,* was supported by the contributions of James Alexander and other leaders of the popular party, much as James Franklin's crusading paper in Boston had been aided by a group of dissident writers there. When Zenger was jailed in 1734, Cosby disbarred the attorneys who were defending him, and Andrew Hamilton, a famous Philadelphia lawyer, was brought in to plead his case. Hamilton's masterly argument brought acquittal, was later reprinted as a pamphlet and did much for the cause of liberty.

3. Other Colonial Beginnings.—The initial papers in other colonies were *Maryland Gazette,* Annapolis, 1727, and *Virginia Gazette,* Williamsburg, 1736, both founded by William Parks, one of the best of the colonial printers; *Rhode-Island Gazette,* Newport, 1732, founded by James Franklin, who had moved his press there from Boston but was able to maintain the paper for only eight months; *South-Carolina Gazette,* Charleston, 1732, founded by one of Benjamin Franklin's printers, and carried on by another Franklin protégé, the talented Lewis Timothy; *North-Carolina Gazette,* New Bern, 1755, founded by James Davis; *Connecticut Gazette,* New Haven, 1755, founded by Timothy Green; *New-Hampshire Gazette,* Portsmouth, 1756, founded by Daniel Fowle, a paper which lived for 190 years; *Georgia Gazette and Weekly Mercury,* Savannah, 1763, founded by James Johnston; *New-York Gazette,* 1776, by chance New Jersey's first paper, since Hugh Gaine moved this sheet to Newark when the British occupied New York. John Adams, a Wilmington printer, is reported to have published a paper called the *Courier* in that town for a few months in 1762, but the earliest Delaware paper of which there is definite knowledge is the *Delaware Gazette,* begun at Wilmington in 1785 by Jacob A. Killen. The *East-Florida Gazette,* published at St. Augustine in 1783–84 by the Tory editor John Wells, was the first paper in what was later the state of Florida. Timothy Green, fourth of that name in a long line of printers, established the first Vermont paper in collaboration with J. P. Spooner; it was the *Vermont Gazette and Green Mountain Post-Boy,* of Westminster. The first paper in what is now Maine was the *Falmouth* (Portland) *Gazette,* founded in 1785 by Benjamin Titcomb, Jr., and Thomas B. Wait.

4. Patriots and Tories.—Leading patriot newspapers during the period extending from the enactment in 1765 of the Stamp act, which taxed the newspapers and aroused them to bitter opposition and noncompliance, to the end of the American Revolution were: the *Boston Gazette,* to which Samuel Adams and his group contributed; the *Massachusetts Spy,* founded in 1770 by Isaiah Thomas, who was later a successful book publisher as well as journalist and the founder of the American Antiquarian society; the *Connecticut Courant* of Hartford, founded in 1764 by Thomas Green; the *New-York Journal,* founded in 1767 by John Holt; the *New-York Packet,* founded by Samuel Loudon in 1775; the *Pennsylvania Journal,* founded in 1742 by William Bradford, grandson of the pioneer printer of the same name, himself an able editor and the outstanding soldier-editor of the Revolution; the *Pennsylvania Gazette,* conducted at this time by David Hall; the *Pennsylvania Packet,* founded in 1771 by John Dunlap, another soldier-editor, who later joined with David C. Claypool to make this paper one of the most successful in America during the years immediately after the war; and the *South-Carolina Gazette,* whose war editor was Peter Timothy. These papers had many bitter experiences during the war. While the British occupied Boston, the *Gazette* found a temporary home at Watertown, while the *Spy* moved permanently to Worcester. The New York papers had to find temporary homes in towns up the Hudson river when the city was lost to the patriots, and the patriot papers of Philadelphia were refugees during the shorter British occupation of their city. When Newport was taken, Solomon Southwick buried his press and type; later he exhumed them to continue the long career of his *Mercury.*

Leading royalist papers were: the *New York Gazetteer,* founded in 1773 by James Rivington; the *New-York Weekly Gazette and Mercury,* founded in 1753 by Hugh Gaine; the *Royal American Gazette* of New York; the *Royal Pennsylvania Gazette* of Philadelphia, published briefly by James Robertson; and the *Pennsylvania Evening Post,* founded in 1775 by Benjamin Towne, who was later to make his paper the first American daily.

5. Characteristics of Colonial Papers.—American newspapers in the colonial period were modeled on those of the mother country. The common size was four pages, each about 10 in. by 15 in. Extra pages were sometimes issued to accommodate heavy advertising. Headings of news stories were little more than date lines. The successful papers had good advertising patronage; advertisements were set single-column with little display, so that a page of them resembled modern classified make-up. Paper was obtained chiefly from England until the tax on that staple stimulated American manufacture. The collection of rags from which paper was made was regarded as a patriotic duty during the Revolution. Manufacture of ink, type and presses was also built up in America when importation was interrupted.

Chief news sources were the English newspapers, since interest in events in the homeland was paramount among the colonists. The second important source was "exchanges"—papers published in other American towns. The rule was for an editor to cover any news of first-rate importance in his own neighbourhood for his own paper, and for other papers to clip it; thus all colonial papers were members of an informal co-operative news-gathering system. Local news coverage was not intended to be thorough, and small happenings were usually disregarded; there were no local reporters, and the editors were commonly imbued with the concept of news as historical record. Other sources than those mentioned were letters from other cities or from England brought in by friends of the editor; word-of-mouth reports by ship captains, postriders and travelers; and official documents and communications. With the coming of the war, English papers were cut off almost entirely, and military operations interfered with colonial communications; but patriot committees were active in

sending news bulletins from one town to another.

There were no editorial pages, but editorial comment was interspersed with the news. Political and economic dissertations, satirical essays on social customs and poetry were common.

6. The Daily Newspaper.—A few semiweeklies and triweeklies had been published in the colonies. For example, Benjamin Towne's *Pennsylvania Evening Post* had been established as a triweekly; in 1783 Towne made it the first American daily. Generally it consisted of only two pages, and was a rather shabby sheet. Towne was indicted for treason a few months after he made his paper a daily, and its 17-month existence in that status was shadowed by its editor's disrepute. John Dunlap and David C. Claypool's *Pennsylvania Packet and Daily Advertiser* began daily publication in 1784. It was very successful, as was the *New York Daily Advertiser*, founded in 1785 by Francis Childs; the latter was the first American paper to be founded as a daily.

Dailies came into the picture less for the purpose of giving timely news than because publishers wished to compete with the coffee-shop bulletins in giving reports to merchants of the offerings of importers just as soon as ships arrived in the harbours of Philadelphia and New York. The political papers of the cities also adopted daily publication rather generally by the end of the 18th century, leaving the weeklies to the smaller towns.

7. The Party Press.—As national issues developed, newspapers took up the cudgels of partisan strife. From the second administration of George Washington until after the Civil War, ardent partisanship in journalism was the rule. The mercantile papers, as well as those confessedly established as political organs, took sides; and when the penny papers appeared in the 1830s, with their emphasis on local news and human-interest features, they, too, were soon involved in party controversy. At its height during the first two decades of the 19th century, this partisanship resulted not only in slanting and distorting news but in personal abuse and vilification of political figures, duels and assaults among editors and much prostitution of the newspaper's chief duty of disseminating the news accurately, fairly and fully. The situation improved in the 1840s and 1850s, but it was not until the doctrine of partisan independence made its great gains in the 1870s that biased reporting of public affairs was largely abated.

First national political organ was John Fenno's *Gazette of the United States* (1789–1818), Federalist, established at New York when the capital was situated there and later moved with the government offices to Philadelphia. Its great rival in the latter city was Philip Freneau's *National Gazette* (1791–93), Republican (Democratic). Alexander Hamilton and Thomas Jefferson, rivals in Washington's cabinet, were the respective sponsors of Fenno and Freneau in their editorial efforts. Supplanting the *National Gazette* as spokesman for the Jeffersonian Republicans was the *Philadelphia Aurora*, founded by Benjamin Franklin Bache, grandson of Benjamin Franklin, in 1790. Another notable political paper in that city was *Porcupine's Gazette* (1797–99), edited in vitriolic fashion by William Cobbett, at the time a refugee from England. In Boston Benjamin Russell's *Columbian Centinel* became a nationally recognized Federalist organ; founded in 1784, it was in many respects an excellent newspaper. Noah Webster, later famous as a lexicographer, founded the *American Minerva* in New York in 1793 as a Federalist organ; four years later this paper adopted the name *Commercial Advertiser*, which it kept for more than a century.

One cause of the Alien and Sedition acts (1798–1801) is to be found in the prevailing scurrility of attacks on public officers, but the immediate occasion was the threat of war with France and the consequent need to guard against disloyalty. There were about 25 arrests under the Sedition act and 11 trials resulting in 10 convictions. Actions under the common law brought total convictions to 15, of which 8 related to newspapers. But the censorship involved was greater than these figures indicate. The acts expired with the John Adams administration. Two years later Alexander Hamilton, in an argument for a new trial in the case of Harry Croswell, editor of the *Hudson* (N.Y.) *Wasp*, advanced the "Hamiltonian doctrine," later made a part of most state constitutions, to the effect that evidence of the truth of statements published with good intentions may be introduced by the defense in a criminal libel suit.

The *National Intelligencer*, established in Washington in 1800 as the organ of the Jefferson administration by Samuel Harrison Smith, proved to be mild in partisanship and reliable in news. Conducted after 1810 by Joseph Gales, Jr., and W. W. Seaton, the *Intelligencer* was considered by other papers for many years as the authority on Washington news. It was displaced as the government organ, however, when Andrew Jackson became president. Duff Green's *United States Telegraph* (1825) was Jackson's first Washington paper; it was supplanted in 1830 by the *Washington Globe*, edited by Francis P. Blair. Associated with the *Globe* also were Amos Kendall, editorial writer, and John C. Rivers, business manager, who, with Blair, were members of Jackson's "kitchen cabinet" of political advisers.

Meantime, in New York, James Cheetham's *American Citizen* was the vituperative organ of the George Clinton faction of the Democratic party during the first decade of the 19th century. Established largely in order to combat Cheetham's sheet was the *New York Evening Post*, founded in 1801 by Alexander Hamilton and friends associated in a joint-stock company. William Coleman was its first editor; he was followed in 1829 by William Cullen Bryant, who edited the paper until his death in 1878.

8. The Penny Press.—The chief characteristics of the penny press of the 1830s were smaller size, a one-cent price in comparison with the six cents charged by the larger papers, and adaptation to lower economic and social levels of readership. The penny papers featured local and human-interest matter, preferred news above support of a party or mercantile class, exposed abuses of banks and churches and tended to give a realistic picture of the news scene despite taboos.

The first successful penny daily was the *New York Sun*, founded in 1833 by Benjamin H. Day. Most important of its rivals in this field was the *New York Herald*, begun two years later by James Gordon Bennett. Three New York printers, William M. Swain, A. S. Abell and A. H. Simmons, founded the *Philadelphia Public Ledger* in 1836 and the *Baltimore Sun* in 1837; Swain was chiefly responsible for the former and Abell for the latter over many years. In 1841 Horace Greeley founded the *New York Tribune* as a penny paper, and ten years later the *New York Times* was started by Henry J. Raymond, George Jones and Edward B. Wesley at the same price. All these New York papers except the *Sun* soon went to the two-cent price, enlarging their size and scope. The penny papers initiated what may be called modern journalism by their emphasis on local news and timeliness. They were leaders in the use of expresses and the telegraph for quick transmission of news, and their large circulation and advertising receipts enabled them to improve their news services and install fast cylinder presses.

Bennett and Greeley, rival editors through three decades (both died in 1872), were leading figures in a period of personal journalism. Bennett was one of the most original of editors, initiating financial and society departments and playing a part in many other innovations. Greeley was the great idealist, a crusader against slavery and intemperance and in favour of westward expansion. His hospitality to new ideas brought Fourierism, spiritualism, women's rights, Grahamism and many other reforms and fads into the columns of the *Tribune*. His alliance with Thurlow Weed, the political boss who was editor of the *Albany Journal*, 1830–63, and William H. Seward was dissolved in 1854 by a letter in which he showed his resentment because he had not been given political office; later he had much to do with the defeat of Seward for the Republican presidential nomination. The *Tribune* did not always support Lincoln during his administration, however.

In Springfield, Mass., the *Republican* was begun as a two-cent daily in 1844. Its weekly edition had been founded by Samuel Bowles 20 years earlier, but the daily was the project of a son, also called Samuel, aged 18. It became one of the most famous of small-city dailies, and exerted a wide influence, largely through its weekly edition, for many years. Following a printers' strike in 1947, it was reduced to the status of a Sunday paper.

In New Orleans, George W. Kendall and Francis Lumsden started the *Picayune* in 1836, and it soon gained a wide reputation not only as a good newspaper but as a repository for amusing sketches and witty paragraphs. During the Mexican War Kendall became the first important and regular reporter of military actions from the field.

The war with Mexico was a great stimulant to speed in news transmission. The expense of efforts in this direction led to the first important effort in co-operative news gathering—a news agency in New York city in 1848 that was the forerunner of the present Associated Press. This group consisted of the *Sun, Herald, Tribune, Express, Courier and Enquirer* and *Journal of Commerce*—the leading papers of the metropolis. When the *Times* was begun, it was taken in. The *Express* (1836–81), conducted by James and Erastus Brooks, was a strong mercantile paper. The *Courier and Enquirer* was the result of a merger in 1829 of Mordecai M. Noah's *Enquirer* and James Watson Webb's *Morning Courier*. Under Webb's aggressive editorship it was bright, bellicose and enterprising. The *Journal of Commerce* was founded in 1827 by Arthur Tappan as a commercial paper with a strong religious bent; it soon became the property of Gerard Hallock and David Hale.

9. The Westward Movement.—The first newspaper west of the Appalachians was the *Pittsburgh Gazette* (*Gazette Times*, 1906; *Post-Gazette*, 1927), founded by John Scull and Joseph Hall in 1786. The following year the *Kentucky Gazette* was founded at Lexington by John Bradford. First paper in what is now West Virginia was the *Potowmac Guardian*, begun by Nathaniel Willis in 1790. Tennessee's first paper was the *Knoxville Gazette*, 1791, George Roulstone founder. Benjamin M. Stokes started the first Mississippi paper, the *Mississippi Gazette* (1799–1801) at Natchez. The first New Orleans paper was *Moniteur de la Louisiane*, a sheet of four small pages in French, 1794, by Louis Duclot. The earliest paper in what is now Alabama was the *Mobile Centinel* (1811–12) by Samuel Miller and John B. Hood.

First newspaper to be established in what is now Ohio was the *Centinel of the North-Western Territory*, founded at Cincinnati by William Maxwell in 1793. First in Indiana was Elihu Stout's *Indiana Gazette*, later *Western Sun*, at Vincennes in 1804. Joseph Charless founded the *Missouri Gazette* in 1808; it was the first paper printed wholly in English west of the Mississippi. Its name was later changed to *Missouri Republican* and in 1888 to *Republic;* it was merged with the *St. Louis Globe-Democrat* in 1919.

First Michigan paper was the *Michigan Essay*, produced briefly under the patronage of Gabriel Richard, a Catholic missionary; the first Michigan paper of longer life was the *Detroit Gazette* (1817–30). In 1814 Matthew Duncan brought his press up from Kentucky and founded Illinois' first paper at Kaskaskia, the *Illinois Herald*, which he later moved to the new capital at Vandalia and renamed the *Illinois Intelligencer*. The first Chicago paper was the *Democrat*, founded in 1833 by John Calhoun, later mayor of the city; it was merged with the *Tribune* in 1861. In 1819 the *Arkansas Gazette* was begun by William E. Woodruff at Arkansas Post; it was moved to Little Rock when that settlement was chosen as the capital.

First newspaper in Wisconsin territory was the *Green Bay Intelligencer* (1833–36). First in Iowa was John King's *Dubuque Visitor* of 1836, and first in Minnesota James M. Goodhue's *Minnesota Pioneer* of 1849, later famous as the *St. Paul Pioneer Press*. In 1854 the *Nebraska Palladium*, which had been begun in Iowa, was moved across the river to Belleview and published for several months in the new territory. First Kansas paper was a missionary sheet in an Indian language called in English *Shawnee Sun*, published in 1835 at the Baptist mission; first English-language paper in that territory was the *Kansas Weekly Herald* (1854–61) of Leavenworth. The pioneer Kansas papers were embroiled in the free-state war of 1855. The *Lawrence Herald of Freedom* office was destroyed by the proslavery faction, but it gave its type to be molded into balls used for the attack on Fort Titus, so that the discharges of the antislavery cannon were called "new editions" of the *Herald*.

The *Sioux Falls Democrat* was first of South Dakota papers in 1858; its name was soon changed to *Northwestern Independent*. The *Fort Union Frontier Scout* of 1864 was North Dakota's first paper.

In the southwest Oklahoma's first paper was a Baptist missionary organ, the *Cherokee Messenger*, printed in an Indian language, near the present site of Westville, in 1844–46. Pioneer Texas paper was the organ of the provisional revolutionary government at San Felipe called *Telegraph and Texas Register*, 1835; it had an adventurous career before it became the first Houston newspaper. A small campaign sheet called *El Crepusculo*, published in Santa Fe by Antonio Barreiro, was apparently the first publication in New Mexico, but the first real newspaper was the *Santa Fe Republican* (1847–49), with two pages in English and two in Spanish. The *Weekly Arizonian*, Tubac, 1859, was the first paper in Arizona.

California's first paper was founded in 1846. It was a small sheet printed on one side only at Monterey, and was called the *Californian*. It was soon moved to what is now San Francisco, where the *California Star* had been established in 1847. Both were absorbed into the *Alta California* when that famous paper was set up in 1849. The first paper printed in Nevada was the *Territorial Enterprise*, begun in 1858 at Genoa, but more famous as the Comstock lode organ at Virginia City, where Mark Twain and Dan De Quille worked on it. Another gold rush brought Colorado's first paper, the *Rocky Mountain News*, founded in Denver by William N. Byers in 1859; it became a Scripps paper in 1926. Other western "firsts" were the *Oregon Spectator*, Oregon City, 1846; the *Columbian*, Olympia, Wash., 1852; the *Deseret News*, famous Mormon paper in Salt Lake City, Utah, 1850; the *Golden Age*, Lewiston, Ida., 1862; the *Montana Post*, begun in 1864 at the Virginia City gold camp and moved to Helena in 1868; and the *Fort Bridger Daily Telegram* of 1863, first Wyoming and first state paper to begin as a daily.

The first paper in what is now Alaska was *Esquimaux*, printed monthly at Port Clarence, Russian America, by John J. Harrington for the Western Union Telegraph expedition in 1866–67. The *Klondike Nugget* was published at Dawson (1898–99) by Eugene C. Allen and was later established as a weekly at Nome. Anchorage, Juneau, Fairbanks and Ketchikan acquired small dailies, and by the mid-1960s there were a dozen weeklies.

The first Hawaiian newspaper was the weekly *Sandwich Island Gazette and Journal of Commerce* (1836–39), by Samuel D. Mackintosh and Nelson Hall, which was continued monthly (1839–40) as the *Sandwich Island Mirror and Commercial Gazette*. Of longer life was James Jackson Jarves' *Polynesian* (1840–64). The first daily was the *Hawaiian Herald* (1866). The chief papers in Honolulu in the mid-1960s were the *Star-Bulletin* and the *Advertiser*. The *Hawaiian Star* was begun in 1893 and the *Evening Bulletin* in 1882; they were merged in 1912 by Wallace R. Farrington, later governor of the territory. The *Advertiser* was founded as a weekly by Henry M. Whitney in 1856. The *Hawaii Times* was founded in 1885 and published in both English and Japanese. In Hilo the daily *Tribune-Herald* was founded in 1895.

10. The Civil War and Reconstruction.—The American Civil War was well covered by special correspondents in the field, more than 150 of whom served northern papers during the war. Military restrictions, government control of telegraph lines and mob violence—all sporadic—curbed press activity; but there was no regular and consistent censorship. A number of papers were forced to suspend publication by military commands or the post-office department.

Among these were the *New York Daily News* and the *Chicago Times*. The *News*, founded in 1855, was a penny paper, organ of the Tammany Democracy; it had come into the hands of Benjamin Wood, brother of Fernando Wood, New York's mayor. The Woods were strongly proslavery, and a combined military and postal blockade forced the *News* to close down for 18 months in 1861–62. After the war this paper won a very large circulation in the tenement-house districts as a penny sensation-monger. Wood lived until 1900, and the next year Frank A. Munsey bought the *News* from his widow for $34,000 in $1,000 bills.

Munsey improved it so much that it lost its public, and it perished in 1900. The *Chicago Times,* founded in 1854, had been bought by Wilbur F. Storey in 1861. Its editorial attacks on the Union cause led Gen. A. E. Burnside to seize and suspend the paper, but after three days President Lincoln requested that the order be rescinded. The *Times* became a successful sensation paper after the war, receding only as the *Tribune* came to control the Chicago morning field and absorbed the *Times* in 1895.

The *Chicago Daily Tribune* was founded in 1847; it had a difficult time until Joseph Medill and five partners (including Charles H. Ray and Alfred Cowles) took it over in 1855. After Medill gained control of the paper in 1874, he directed its destinies until his death 25 years later, making it a strong and successful paper.

A leading newspaper development of the 1870s was the rise of the *New York Sun* in prestige and influence. Purchased in 1868 by Charles A. Dana and associates, it soon became one of the best-written and edited papers in the country, independent in politics, bright and saucy, its human-interest stories of the great city one of its chief attractions. The *Evening Sun* was launched in 1887.

Notable in the 1870s also was the growing independence of the press from party control. Dating from the secession of Republican papers from the Ulysses S. Grant forces in 1872, what was sometimes called the "mugwump" movement gained in strength and caused the defeat of James G. Blaine in 1884. By 1880 one-fourth of American newspapers were listed in the directories as independent; by 1890 the proportion had reached one-third. By the 1950s one-half of the daily papers listed themselves as "independent" and another one-fourth as "independent Republican" or "independent Democratic."

11. The "New Journalism."—Joseph Pulitzer, Hungarian-born immigrant who had made a success of the *St. Louis Post-Dispatch*, which he had formed in 1878 of the unimportant *Dispatch* (founded 1864) and John A. Dillon's *Post* (founded 1875), upset the New York newspaper situation in the 1880s and did more than anyone else to set the pattern of modern journalism. In 1883 he bought the *New York World* and soon made it the country's most successful newspaper.

The *World* had been founded in 1860 by Alexander Cummings as a religious daily, but it did not flourish and soon came into the hands of Democratic politicians and financiers. In 1869 Manton Marble purchased majority control, and under his editorship the paper was influential and moderately successful. When he retired in 1876 the *World* came under the control of Thomas A. Scott of the Pennsylvania railroad, who unloaded it on Jay Gould in connection with a railroad deal. The paper had been losing $40,000 a year when Pulitzer bought it. The *Evening World* was established in 1887. The *Sunday World*, with a record-breaking circulation of 250,000, consisted of 26 to 44 pages, half advertising. The combined circulation of the dailies (374,000 by 1892) exceeded those of any two competitors. The *World* had become the most profitable paper published.

Other important New York papers in the 1870s and 1880s besides the *World, Sun* and *Daily News* were the *Herald*, under the control of James Gordon Bennett, Jr., 1872–1918, during which time he lived chiefly in Paris; the *Tribune*, under Whitelaw Reid, 1872–1905, which combined with the *Herald* to become the *Herald Tribune* in 1924; the *Evening Post*, under Edwin Lawrence Godkin, 1883–99; the *Times*, under George Jones, 1869–91; the *Commercial Advertiser*, descended from Noah Webster's *American Minerva*, under Hugh J. Hastings, 1868–83; and the *Mail and Express*, a consolidation formed by Cyrus W. Field in 1882 and edited and published in the 1880s by Elliott F. Shepard.

In Philadelphia a leading paper was the *Public Ledger*, published 1864–94 by George W. Childs. Later it came into the hands of Adolph S. Ochs, who sold it to Cyrus H. K. Curtis, the magazine publisher; Curtis made a great but unprofitable paper of it, and it perished in 1942. The *Record* was founded by William J. Swain in 1870 and published by William M. Singerly, 1877–98. It was published by Thomas B. Wanamaker, 1902–28, and by J. David Stern until it was sold to the *Bulletin* in 1947. The *Press* was founded in 1857 by John W. Forney, conducted in the 1880s by Charles Emory Smith and merged in the *Public Ledger* in 1920. The *Inquirer*, founded in 1829, was long conducted by Jesper Harding and his son William W., and later by the Elverson family; it was bought in 1936 by M. L. Annenberg. The *Times* was founded in 1875 by Alexander K. McClure, to become a great crusading paper. The *Evening Item*, founded in 1847 by Thomas Fitzgerald and conducted by him and his sons for nearly half a century, gained a large circulation. The *Evening Bulletin*, founded on the basis of the *American Centinel* (1816–46) by Alexander Cummings, was Philadelphia's first afternoon paper. In the 20th century, under William L. McLean and his sons, it gained the largest circulation in the city. At the end of 1957, with the purchase of the *Daily News* by the *Inquirer*, Philadelphia had morning and evening newspapers under one ownership.

In Washington, D.C., the *National Republican* (1860–88) was edited by W. J. Murtagh. The *Evening Star*, established in 1852, was purchased in 1867 by a group headed by Crosby S. Noyes and later conducted by his sons Frank B. and Theodore W. Noyes. The *Post*, founded by Stilson Hutchins in 1877, was edited by him until 1889. After a varied career, the *Post* was bought at auction in 1933 by Eugene Meyer, who made it again a successful newspaper.

In Boston the *Herald*, founded in 1846, was a leader under the editorship, 1862–87, of E. B. Haskell. In 1912 it bought the *Traveller*, founded in 1825, as its evening associate. The *Daily Advertiser*, founded in 1813, and made by Nathan Hale the first successful daily in New England, seemed moribund in the 1880s; but it lived to be made a tabloid by William Randolph Hearst in 1938, and later to become the *Sunday Advertiser*. The *Post*, founded by Charles G. Greene in 1831, also declined in the 1880s, but had a rebirth under Edwin A. Grozier in 1891. The *Journal* (1833–1917) was edited by W. W. Clapp in the 1880s in the sensational manner of the "new journalism." The *Transcript* (1830) was edited in this decade by Edward H. Clement; for many years it was the great newspaper organ of Boston culture, but it died in 1941. The *Globe* (1872) was highly successful under Gen. Charles H. Taylor and his son William O.

In Atlanta, Ga., Henry W. Grady in 1880 bought a quarter interest in the *Constitution* (1868) and as its managing editor made it a great newspaper; he died in 1889 and was succeeded by Clark Howell. In Louisville, Ky., Walter N. Haldeman consolidated the *Courier* and *Journal* in 1868, and put in charge Henry Watterson, who made the *Courier-Journal* famous and remained in service until 1919. In Cincinnati, Murat Halstead became editor of the *Commercial* (1843) in 1865; it became the *Commercial Gazette* when it was consolidated with the *Gazette* (1815) and Halstead sold it in 1890. John R. McLean took over the management of the *Cincinnati Enquirer* (1841) in 1870, and bought it from his father in 1881; in 1895 he bought also the *New York Journal* and in 1905 the *Washington Post*. Cincinnati's evening papers, the *Times* (1840) and the *Star* (1872), were merged in 1880 by Charles P. Taft and in 1958 was purchased by the Scripps-Howard chain. The great San Francisco paper of the period 1870–90 was the *Chronicle*, founded in 1865 by two brothers in their teens, Charles and Michel H. de Young; it was a lively, fighting paper, and Charles de Young was shot and killed in 1880 in connection with a political fight. The *Call* (1856) and the *Bulletin* (1855) were under the same management; much later (1928) they were consolidated by Hearst. The *San Francisco Examiner* (1865) was bought by George Hearst in 1880 to further his political ambitions. In 1965 the *Examiner* and the *News-Call Bulletin* were merged as an afternoon paper and consolidated, on a cost-sharing basis, with the morning *Chronicle*.

The great event in Chicago journalism in the post-Civil War period was the founding of the *Daily News* as a penny paper by Melville E. Stone in 1875. When the paper was on the verge of failure after a few months, Victor F. Lawson came in as partner, bringing needed capital. A liberal, crusading paper, the *Daily News* made a great success. In 1888 Stone sold out to Lawson, later becoming the first general manager of the re-

organized Associated Press. John S. Knight bought the paper in 1944, and it was sold to the *Chicago Sun-Times* in 1959. The *Herald* was founded in 1881 by James W. Scott, who combined it with the *Times* in 1895. The *Times-Herald* became the *Record-Herald* when Herman Kohlsaat, its owner since the consolidation, bought the *Record*, morning edition of the *Daily News*, in 1901 and made a new combination; after Kohlsaat's *Inter Ocean* (1872) was merged in the *Record-Herald* in 1914, it became the *Herald* again, but four years later Hearst bought it and merged it with his *Examiner* as the *Herald-Examiner*, later the *Herald-American* and still later as the *American*. In 1956 it was purchased by the *Chicago Tribune*.

In Kansas City, Mo., William Rockhill Nelson and Samuel E. Morss began the *Star* in 1880 as a small two-cent daily. Morss dropped out on account of ill-health after a year or two, but Nelson made the *Star* a strong, crusading local newspaper, adding a Sunday edition in 1894, buying the *Times* (1868) for its morning edition in 1901 and starting the *Weekly Star* as a farm paper in 1890. Nelson died in 1915 and staff members bought the paper for $11,000,000. Henry J. Haskell was editor 1928–52.

12. Yellow Journalism.—William Randolph Hearst's first paper was the *San Francisco Examiner*, which his father, George Hearst, turned over to him. Successful in his management of that paper, he went to New York in 1895 and bought the *Journal*. With this paper he challenged the supremacy of Pulitzer's *World* in New York. Some of his staff he brought from San Francisco and some he hired away from the *World*. He outdid his rival in sensationalism, crusades and Sunday features. A comic picture series called "The Yellow Kid" was drawn by Richard F. Outcault for the *Sunday World* and later for the *Sunday Journal*, but after the departure of the originator to the rival paper it was drawn by George B. Luks for the *World;* these picture series excited so much attention that the competition between the two newspapers came to be called "yellow journalism." This all-out rivalry and its accompanying promotion developed large circulations for both papers and affected U.S. journalism in many cities. The "yellow journalism" formula, as it developed, was distinguished by (1) "scare heads" in large type, printed in black or red; (2) lavish use of pictures; (3) pseudoscientific articles; (4) the Sunday supplement, with coloured comics and sensational features; (5) ostentatious crusading for popular causes. The era of "yellow journalism" may be said to have ended shortly after the turn of the century, with the *World's* gradual retirement from the competition in sensationalism and the rise of the *Times*.

One of the phenomena of the era was the promotion of the war with Spain through hysterical propaganda against that nation based on exposures of Spanish atrocities in Cuba. This jingoism was not limited to the *Journal* and *World*, though they were leaders in it. Some techniques of the "yellow journalism" period became more or less permanent and widespread, as banner headlines, coloured comics and copious illustration.

Adolph S. Ochs, publisher of the *Chattanooga* (Tenn.) *Times*, took over management of the failing *New York Times* in 1896. In 1898 Ochs reduced the price of the paper to one cent. Instead of getting into the "yellow" competition, the *Times* adopted the slogans "All the news that's fit to print" and "It does not soil the breakfast cloth." Ochs, who had actually put in only $75,000 in 1896, had a controlling interest by 1900. The *Times's* success as a clean, conservative newspaper was one of the most striking phenomena of the new century.

13. "Chains" and Consolidations.—If a newspaper "chain" is defined to include affiliations formed by coöperation rather than common ownership, the groups of colonial papers of which Benjamin Franklin and Isaiah Thomas were patrons and sometimes part owners might be said to be the first American chains. But modern chains began with the Scripps papers in 1878. By 1900 eight such groups could be listed; by 1910 there were a dozen and the number of papers in them had doubled. In the next decade the number of chain papers doubled again; and in the 1920s the number of chains reached more than 50, and the number of papers in them about 300. In the 1960s there were more than 100 chains—owners of about one-third of the nation's 1,700 dailies.

The first paper founded by E. W. Scripps (with assistance from his half brothers James E. and George) was the *Cleveland Press*, begun in 1878 as a penny paper. Successful there, he persuaded his half brothers to buy the *St. Louis Chronicle* (1880–1905), with which he failed to overcome the dominant competition of the *Post-Dispatch* and *Globe-Democrat*. A little later he bought a controlling interest in the *Cincinnati Post* (purchase of the *Times-Star* and merging of it with the *Post* in 1958 gave the Scripps-Howard chain control of all daily papers) and founded the *Kentucky Post* at Covington. By this time he had developed his formula: establish papers in medium-sized cities, put young men from his organization in charge with working partnerships, sell for a penny a copy and campaign for popular causes. With Milton A. McRae as partner in the Scripps-McRae league, he bought or founded many papers in the midwest in the years 1897–1911. McRae dropped out in 1914, and in 1917 Scripps placed management in the hands of two sons, James G. and Robert P. Scripps. Three years later, James was supplanted by Roy W. Howard, who had been general manager of the United Press associations, founded in 1907 as the Scripps news-gathering agency.

In 1922 E. W. Scripps retired completely, turning over his newspaper properties to his son Robert, who formed the organization known as Scripps-Howard. Chief Scripps-Howard additions to the chain in the 1920s were the *Pittsburgh Press* (1884) in 1923 and *New York Telegram* (1868) in 1927. Most important of all was the purchase of the *New York World* in 1931, and its merger with the *Telegram*. To this combination the *Sun* was added in 1950. In 1966 the *World-Telegram and Sun*, the *Journal-American* (1937) and the *Herald Tribune* (1924) were merged, by corporate agreement among the three owners (Scripps-Howard, Hearst and John Hay Whitney, respectively), to become an afternoon and Sunday paper, the *World Journal Tribune*. This paper, however, ceased publication in 1967.

The Hearst chain began with the *San Francisco Examiner* and the *New York Journal* and *Evening Journal*. In 1900 Hearst founded the *Chicago American*, in 1902 the *Examiner* and in 1904 the *Boston American*. Beginning in 1917, he added many more papers to his list, buying as many as seven in one year (1922). He bought or established altogether more than 40 daily papers, 16 of which he owned at the time of his death in 1951.

Though the Scripps and Hearst chains were the largest of such systems, there were many other groups, such as the Booth newspapers in Michigan, founded by George C. Booth; the Brush-Moore newspapers in Ohio, founded by Louis H. Brush and Roy D. Moore; the Lee syndicate in the upper Mississippi valley, founded by Alfred W. Lee; the Copley Press in Illinois and California, founded by Ira C. Copley; the nationwide Speidel newspapers, founded by Merritt C. Speidel; the Frank E. Gannett newspapers, chiefly in New York; the James M. Cox newspapers at Dayton and Springfield, O., Miami, Fla., and Atlanta, Ga.; Central newspapers, founded by E. C. Pulliam, chiefly in Indiana; the H. C. Ogden newspapers in West Virginia; the John H. Perry newspapers, chiefly in Florida; Stauffer publications, Oscar Stauffer president, in Kansas, Missouri and Oklahoma; Ridder publications, built up by the sons of Herman Ridder in New York, Minnesota and on the west coast; the Knight newspapers, owned by John S. Knight, comprising the *Chicago Daily News* (sold in 1959 to the Field Enterprises, publisher of the *Chicago Sun-Times*), the *Detroit Free Press*, the *Miami* (Fla.) *Herald*, the *Akron* (O.) *Beacon Journal* and the *Charlotte* (N.C.) *Observer*; and the group rising in the 1950s under the direction of S. I. Newhouse, including the *St. Louis Globe-Democrat*, the *Portland Oregonian*, the *Syracuse* (N.Y.) *Post-Standard* and the *Birmingham* (Ala.) *News*.

Consolidations, like chains, were not new in modern journalism. Ever since the consolidation of the *New-England Weekly Journal* with the *Boston Gazette* in 1741, weak papers had been absorbed by strong ones. But the large newspaper capital investments which, beginning in the 1890s, came to characterize the newspaper business of the 20th century made the merger a recognized technique for "cleaning up" a ruinous competitive situation. Especially dangerous, it seemed to critics of the modern communications

system, was the increasing number of large cities with only one newspaper ownership; by 1940 this was the case in more than one-fourth of U.S. cities of more than 100,000 population. Moreover, the number of daily newspapers in the United States declined from a peak of 2,519 in 1916 to 1,850 in 1945. Slight increases marked the latter half of the 1940s, but in 1955 the total was 1,841. In 1963 the total was 1,854. (These figures are from N. W. Ayer and Son's *Directory of Newspapers and Periodicals*; see *Bibliography*.)

Newspaper consolidation was dramatized about 1920 by Frank A. Munsey's activities. In 1916 Munsey bought the *New York Sun, Evening Sun* and *Press* and merged the *Press* in the *Sun*. Four years later he bought the *Herald* and its evening associate, the *Telegram*, and merged the *Sun* in the *Herald*, changing the name of the *Evening Sun* to *Sun*. His next move was to sell the *Herald* to the *Tribune* for another merger in 1924. Then he bought the *Globe*, which had been merged with the *Commercial Advertiser* in 1905, and merged it with the *Sun*. His last consolidation was that of the *Mail and Express* and the *Telegram* in 1924.

14. Varied Newspapers.—The *St. Louis Globe-Democrat* had been formed when J. B. McCullagh in 1875 bought the *Missouri Democrat* (founded 1852) and merged it with his *Globe* (founded 1872). The *St. Louis Star-Times* was formed in 1935 by the consolidation of the *Star* (founded 1878), which had absorbed the *Chronicle* (1905), and the *Times* (founded 1895). It was merged with the *Post-Dispatch* in 1951.

The Denver *Post*, founded in 1892, was purchased three years later by Fred G. Bonfils and Harry H. Tammen and made an outstanding exemplar of the "yellow journalism" of the period. Tammen died in 1924 and Bonfils in 1933; in 1946 Palmer Hoyt became publisher, modifying the policy of the paper. Edgar Watson Howe founded the *Atchison* (Kan.) *Globe* in 1877, and made it a widely quoted paper. Another famous editor in a small Kansas city was William Allen White, who bought the *Emporia Gazette* when it was five years old in 1895 and soon achieved national fame through his editorial writings.

The *Christian Science Monitor* was established in Boston by Mrs. Mary Baker Eddy in 1908. A handsome and high-minded general newspaper, it fought "yellow journalism" and emphasized international news The *Des Moines Register* was begun in 1856 as the *Iowa Citizen*, a Free Soil paper. From 1870 to the end of the century the *Register* was published by Coker F. Clarkson, followed by his two sons; in 1902 it absorbed the *Leader*, which had been begun as the *Iowa Star*, Des Moines's first newspaper, in 1849. The next year the combined paper was bought by Gardner Cowles, who in 1908 gave it the two-year-old *Tribune* as an evening associate. Following the retirement of Cowles, the *Register* and *Tribune* were conducted by his sons John Cowles and Gardner Cowles, Jr., who in 1935 purchased the *Minneapolis Star* and later the *Journal* and *Tribune* of that city. In 1949 the Minneapolis papers were reduced to two—the *Tribune* for morning and the *Star* for afternoon.

The *New Orleans Times-Picayune* was a combination of the two papers of that city which survived the Civil War period—the famous old *Picayune* and the *Times-Democrat* (founded 1863 1875; merged 1881). The *States* became its evening associate in 1933. The *Item* (1877) and *Tribune* (1924) were sold in 1949 to David Stern, son of the former publisher of the *Philadelphia Record*. In 1958 the *Item* was merged with the *States*, the merger being jointly owned by the *Times-Picayune*. The *Washington* (D.C.) *Times-Herald* was formed in 1939 when Mrs. Eleanor Patterson, granddaughter of Joseph Medill, bought the two papers from Hearst. The *Herald* had been founded in 1906 by Scott C. Bone, who had been managing editor of the *Washington Post*; the *Times* (1894) had been under Munsey ownership 1901–17. Mrs. Patterson left the *Times-Herald* to seven executives of the paper on her death in 1948; but the next year they sold it to Robert R. McCormick, publisher of the *Chicago Tribune*. It was merged with the *Post* in 1954.

15. The Tabloid.—The earliest American newspapers were all tabloids, if by that term only the small size of the pages is meant. The experimental Jan. 1, 1900, issue of the *New York World*, designed and edited by Alfred Harmsworth (later Viscount Northcliffe) and called by him a "tabloid newspaper" and "the newspaper of the 20th century," had the small page size and an emphasis on condensation. Tabloid journalism had come to stand for three techniques by the 1940s: (1) the folded-in-half page size, as compared with that of the normal eight-column paper; (2) the devotion of a large proportion of the paper's space to pictures; and (3) a terse, condensed and lively presentation of the news.

Two grandsons of Joseph Medill, Robert R. McCormick and Joseph Medill Patterson, took over jointly the management of the *Chicago Tribune* in 1914. Five years later they formed a subsidiary of the Tribune company to publish the *New York Daily News* as a new morning tabloid. In 1925, when the paper had reached nearly 1,000,000 circulation—largest in the U.S.—Patterson left his executive position on the *Tribune* and until his death in 1946 devoted himself to the management of the *Daily News*.

The sensationalism of the *Daily News* in the 1920s brought it into competition with Hearst's morning *American*, and Hearst first tried out the form in Boston by "tabbing" the *Daily Advertiser* and then founded the tabloid *Daily Mirror* in New York in 1924. Three months later Bernarr Macfadden began the *Daily Graphic* in the same form. Thus began the "war of the tabs" in New York, in which the three competitors tried to outdo each other in sensationalism. The *Graphic* perished in 1932, to be revived in 1955; the *Daily News* cleaned up its columns and prospered, and Hearst sold the *Mirror* in 1928. Later Hearst had to take the *Mirror* back and it went on to a 1,000,000 circulation by 1950—second only (among American dailies) to the 2,250,000 of the *Daily News*. Both these circulations declined somewhat in the later 1950s. The circulation of the *Mirror* continued to decline and in 1963 it ceased publication; the *Daily News* purchased its assets. Meanwhile, the success of the leaders among the tabloids had tempted publishers of dailies in other cities to try that form; there were about a dozen U.S. tabloids in 1930, 50 in 1940, 70 in 1950 and about the same number in the 1960s. Most important, besides those mentioned above, were the *Washington News* (1921), the *Philadelphia News* (1925), the *Chicago Times* (1929; later the *Sun-Times*), the *Denver Rocky Mountain News* ("tabbed" 1948), the *Los Angeles Mirror* (begun in 1908 as a tabloid, to become the standard-size morning edition of the *Times* in 1954) and the *New York Post* (the old *Evening Post*, "tabbed" in 1942).

16. Two World Wars.—There were comparatively few U.S. correspondents abroad when World War I broke out in Aug. 1914, and those who were rushed across found themselves hampered on all fronts by censorship. After the arrival of the American expeditionary force in 1918, several hundred U.S. newspaper, magazine and agency men covered the war in various foreign centres and on the several military fronts.

Censorship at the fronts, though often severe and stupid in the early years of the war, was somewhat more tenable after the arrival of the A.E.F. Maj. Frederick Palmer, Associated Press and magazine correspondent, wrote the section of the U.S. field service regulations dealing with war correspondents and was himself chief American censor for six months. Within the United States more than 75 papers had their mailing privileges withdrawn under the terms of the Espionage act. The German-language press declined about one-half. The Committee on Public Information, George Creel, chairman, participated in both propaganda and censorship, and presented to U.S. papers a "voluntary censorship" code.

Most famous of the many camp and field newspapers published by and for U.S. soldiers during World War I was *Stars and Stripes*, continued for 16 months from Feb. 1918.

When the United States entered World War II in Dec. 1941, there were more than 200 U.S. reporters gathering news abroad, mostly in belligerent countries. By the spring of 1943 the number had risen to 435. The U.S. war department accredited during the entire war, for longer or shorter periods, 1,186 American correspondents and news officials, representing all mediums, and

the navy department 460 more. Besides the press associations, 30 individual newspapers and 12 magazines had their own correspondents at the war fronts. Photographers played a far larger part in war reporting than ever before. Most famous of war pictures was that of a flag raising at Iwo Jima in Feb. 1945, taken by Joseph Rosenthal of the Associated Press. Most famous of war correspondents was Ernest Taylor ("Ernie") Pyle, who wrote from England, north Africa, Sicily, Italy, France and the Pacific; he was killed on Ie Shima in the Okinawa campaign. Casualties among writers, photographers and radiomen covering the war numbered 37 killed and 112 wounded, exclusive of combat correspondents. Among the best-known writers who perished were Raymond Clapper of Scripps-Howard Newspaper alliance and Webb Miller of the United Press.

The U.S. Office of Censorship, with Byron Price as director, was created Dec. 19, 1941, and lasted throughout the war. It promulgated the "Code of Wartime Practices for the American Press," which formed the basis for a remarkable co-operative self-censorship. Field censorship on the war fronts varied greatly in efficiency and reasonableness. A number of home periodicals were suppressed, chiefly after convictions of publishers and editors under the Foreign Agents' Registration act. The Office of War Information, with Elmer Davis as director, was set up on June 13, 1942, and handled an immense amount of news and propaganda at home and abroad.

Thousands of army unit, camp and installation, ordnance plant and combat ship papers served the American soldiers in World War II. Of this "G.I. journalism," *Stars and Stripes* was the chief daily newspaper and *Yank* the chief magazine. The former was reborn in London in April 1942 and was later printed in many editions on various fronts. *Yank* was begun about the same time in New York, and came to have 22 editions and a circulation of about 2,500,000. Altogether there were said to be about 600 army unit papers and twice that many camp papers in the United States.

The war of 1950–53 in Korea was thoroughly covered by correspondents of American newspapers and news services. In the first year 320 newsmen, serving all communication agencies, were at the front for varying periods. Nine correspondents were killed and many wounded and taken prisoner.

17. Marshall Field's Newspapers.—The New York tabloid *PM* was founded in 1940 by Ralph Ingersoll and associates as an ad-less daily of liberal opinions. Marshall Field III had some money in it at the start and later increased his holdings to a controlling interest. Sold in 1948, its name was changed to the *Star*, but it perished the next year. Ted O. Thackrey, former editor of the *Post*, founded the *Daily Compass* in 1949 with the financial backing of Mrs. Anita McCormick Blaine, publishing from the *Star's* former plant.

Marshall Field III founded the *Chicago Sun* in 1941 as a competitor for the *Tribune* in the morning field. Six years later he bought the *Times*, evening tabloid, and "tabbed" the *Sun;* in 1948 the two papers were combined as the *Sun-Times* with round-the-clock publication (since 1950, morning only). In its competition with the *Tribune*, the *Sun* felt the lack of an Associated Press membership, which it did not obtain until the government had brought suit against the A.P. for violation of the Sherman Anti-Trust act. This suit, instituted in 1942, was decided in favour of the government in 1945 and caused the A.P. to amend its rules to forbid the "blackballing" of competitors. In 1959 Field Enterprises bought the *Chicago Daily News*.

18. American Newspaper Guild.—The American Newspaper guild was organized in 1933 "to preserve the vocational interests of its members and to improve the conditions under which they work by collective bargaining, and to raise the standards of journalism." First contract negotiated was with the *Philadelphia Record*. In 1936 the guild affiliated with the American Federation of Labor, and the next year with the Committee for Industrial Organization. By mid-century it had 23,000 members and had contracts in force on about 175 dailies and several independent newspapers, as well as on other periodicals and with the news-gathering agencies. There were many strikes, some of which forced suspension of newspapers. One of the strikes, called by the International Typographical union (organized 1850) against the Chicago papers on Nov. 24, 1947, lasted 22 months. The papers resorted to "cold type" production methods, printing from plates made directly from typewritten ("varityped") copy.

19. Circulations and Profits.—In the 1950s the aggregate circulation of English-language dailies increased steadily, passing the 58,000,000 mark in 1959. Advertising business also increased, especially in the mid-1950s. It was estimated that in the years 1947–54 daily newspaper income increased over 100%. At the same time, however, costs rose more than 133%, thus greatly diminishing the margin of profit. Most dailies increased the price per copy to five cents, some to seven and a few to ten.

20. Weekly Newspapers.—Though the urban shift which began after the Civil War tended to highlight the metropolitan daily with its large circulation and fast service, the weekly newspaper of the small towns remained a powerful influence on the lives and thinking of a large part of the population of the U.S. The number of these community papers increased 1870–90 from fewer than 4,000 to about 12,000; the peak was reached in 1914 at 14,500, but consolidations reduced the number to about 10,000 shortly after mid-20th century. From the handwork of 1900, with much dependence on ready-printed sheets, the community weekly developed into a machine-set, power-driven operation, with strong emphasis on community service. In 1953 the Western Newspaper Union, which had furnished "ready prints" to weeklies since 1880, discontinued that service.

Nearly half the population increase of the 1940s took place in the suburbs of the metropolitan areas. This residential movement caused a shift in types of newspapers serving the newly populous centres. Two types grew up rapidly: the "middle-size" dailies, which served sizable suburbs or groups of suburbs (typical of these was *Newsday*, Garden City, Long Island); and the neighbourhood weeklies, often associated in groups. The latter type was by no means limited to suburban centres; it was found singly in small cities and made its most spectacular showing in groups in residential areas of Chicago and Philadelphia.

21. Foreign-Language Newspapers.—Benjamin Franklin was publisher of the first foreign-language newspaper in what is now the United States. It bore the title *Philadelphische Zeitung*, but it published only two issues, in 1732. Most notable of this class in the 18th century was Christopher Sauer's paper published 1739–78 under various titles but most prominently as the *Germantowner Zeitung*. The first daily in a foreign language was *Courrier Français* of Philadelphia, which supported the French cause in America in 1794–98. The phenomenal growth of the foreign-language press, however, waited upon the great waves of immigration, especially those from Germany. In 1830–60 German papers were founded in nearly all the states; and French, Italian, Spanish, Dutch, Swedish, Norwegian and Welsh languages were represented. By 1860 nearly 10% of the country's papers were in foreign languages, and two-thirds of these were in German. *New Yorker Staats-Zeitung*, foremost of them, was founded by Jacob Uhl in 1834 and was later conducted through successive periods by Oswald Ottendorfer and Herman Ridder. Though the foreign-language press reached its peak in the first decade of the 20th century, it declined relative to the growth of English-language papers in the United States after about 1880. Two world wars served to destroy the major prosperity of the foreign-language press. There were 140 dailies (about one-third German) in 1914; a decade after the end of World War II there were 76 (4 of them German, 12 Chinese). At the latter date 35 languages were represented.

22. The Negro Press.—The first Negro newspaper was *Freedom's Journal*, conducted in New York in 1827 by Samuel Cornish and John B. Russwurm. Like all Negro journals published before the Civil War (about 24 in number), this paper devoted a short life to the antislavery cause. The most important paper conducted by a Negro in the years after the war was the *New York Age*, founded in 1879 by the poet and essayist T. T. Fortune under the name of the *Globe*. In the 1950s it was for a time called the *New York Age-Defender* and was subsequently absorbed in the New York edition of the *Courier*.

In the 1960s there were about 90 Negro weeklies and semi-weeklies (excluding religious and other special interest papers) and two dailies, the *Atlanta World* (1928) and the *Chicago Daily Defender* (1956). The circulation of both dailies was about 30,-000. Circulation leaders among the weeklies included the *New York Amsterdam News* (1909), about 60,000; the *Courier* (1910), with headquarters in Pittsburgh, Pa., and 12 other editions throughout the U.S., with a total circulation of about 77,000; and in the 30,000–40,000 circulation range, the *Baltimore Afro-American* (1892), the *Michigan Chronicle*, Detroit (1936), the *Norfolk* (Va.) *Journal and Guide* (1901), and the weekly edition of the *Chicago Defender* (1905).

23. **Appraisals of the Press.**—Since the hostile criticism of the first American newspaper, *Publick Occurrences*, there has been a fairly steady stream of criticism of newspapers in books, magazines, public speeches and the newspapers themselves. These criticisms, by such men as Charles Dickens, James Fenimore Cooper, Lambert A. Wilmer, David G. Croly, Edwin Lawrence Godkin, Oswald Garrison Villard, George Seldes, Silas Bent, Harold L. Ickes and Herbert Brucker, have ranged from angry invective to sober appraisal, from personal or partisan motivation to the scholarly and sociological attitude. Perhaps the most important investigation was undertaken by the Commission on Freedom of the Press headed by Robert M. Hutchins, then chancellor of The University of Chicago. The commission's report, *A Free and Responsible Press* (1947), restated the principles of press freedom, emphasized dangers of mass publication and monopolistic control and made a series of recommendations, among them creation of an agency independent of press and government to appraise and report to the public on press performance. (F. L. Mt.)

II. UNITED KINGDOM

1. **Beginnings.**—Certain pamphlets may be taken as predecessors of the English newsbooks. *Newes Concernynge the General Councell Holden at Trydent* (Thomas Raynalde, London, 1549), a translation from the German, was one of the earliest. They dealt with political matters, murders, wonders, etc., and were commonly published some time after the events they chronicled. They were not so much budgets of news as "relations" of a single event and matters connected with such an event. As a type they were modeled upon continental (especially German and Dutch) newsbooks, of which they were sometimes translations or adaptations. The German compilations of a half-year's events, called *Messrelationen* because they were sold at the fairs, influenced later periodical development and were significant for England. Such a compilation in Latin by Micael ab Isselt, entitled *Mercurius Gallobelgicus*, continued 1594–1635, was widely popular in England, and brought the name "mercury" into use for newsbooks; some of the later issues were translated into English.

Doubtless under the influence of the *Messrelationen*, briefer compilations, many of which were translated or adapted for English readers, appeared from 1590 onward. When English editors took over the idea of the news budget in 1621, the publications were commonly called "corantos" to indicate running news. The first English-language corantos were, however, small single-sheet (two-page) publications, and they were published in the Netherlands from Dec. 1620 to Sept. 1621. George Veseler published 15 of them and Broer Jonson 6 or 8 in Amsterdam; others were issued in Alkmaar and The Hague. Apparently the next step was the publication of the same type of coranto in London in Sept. 1621, under the title *Corante, or, Weekely Newes From Italy, Germany, Hungarie, Spaine and France*. Six of these were issued "for N. B." with slight variations in title through September and October. The title is nearly enough identical, and the weekly periodicity (though actually irregular) clear enough in intention, to support the claim for this series as the first English newspaper. "N. B." was probably Nicholas Bourne. The sheets were translations of Dutch or German corantos.

The next year the single-sheet corantos gave place to those in pamphlet form; and comparative regularity in periodicity, if not in title, came with the *Weekly Newes*, issued by Nicholas Bourne and Thomas Archer beginning in May 1622. This series was generally referred to as composing the "first English newspaper" before the discovery in 1912 of the single-sheet corantos by "N. B." Continuity was by dates rather than identical title; for several years most coranto publishers depended upon changing headlines to sell their product and avoided identical titles. On Aug. 2, 1622, Nathaniel Butter began a *Newes*, "all of which do carry a like title . . . and have dependence upon one another" (Aug. 23). Butter became the most famous of the coranto publishers who flourished in the 1620s. In Oct. 1622, with Bourne and William Sheffard, Butter began *A Coranto*, with the introduction of serial numbering. In 1625 Archer founded *Mercurius Britannicus*, which probably lasted till the end of 1627. Butter and Bourne remained principal publishers of the corantos of various series until 1632, when all were suppressed because the Spanish ambassador had been offended by news they had published regarding the royal house of Austria. For six years thereafter there were no newsbooks in England, but in 1638 Butter and Bourne were given exclusive patent for publication of foreign news.

2. **Freedom and Censorship.**—The next step in the evolution of the newspaper was due to the abolition of the Star Chamber in 1641, and the consequent freeing of the press; and at last the English periodical with domestic news arrived. In Nov. 1641 began *The Head of Severall Proceedings in the Present Parliament* (outside title) or *Diurnal Occurrences* (inside title), the latter being the title under which it was soon known as a weekly; and on Jan. 31, 1642, appeared *A Perfect Diurnal of the Passages in Parliament*. These were printed for William Cooke, and were written apparently by Samuel Pecke, "the first of the patriarchs of English domestic journalism" (J. B. Williams). The weekly *Diurnals* were on the side of the parliament until in Jan. 1643 appeared at Oxford the first royalist diurnal, named *Mercurius Aulicus, a Diurnal Communicating the Intelligence and Affaires of the Court to the Rest of the Kingdome* (continued till Sept. 1645, and soon succeeded by *Mercurius Academicus*), which struck a higher literary note. It was conducted by Sir John Berkenhead, a fellow of All Souls, whose style is said to reflect that of the parliamentary oratory of his day. He afterward became master of requests. *Mercurius Civicus*, the first regularly illustrated periodical in London, was started by the parliamentarian Richard Collings on May 11, 1643 (continued to Dec. 1646); Collings had also started earlier in the year the *Kingdome's Weekly Intelligencer*, which lasted till Oct. 1649. In Sept. 1643 appeared another puritan opponent of *M. Aulicus* in the later *Mercurius Britannicus* of Capt. Thomas Audley, which in Sept. 1644 was taken over and continued for nearly two years by Marchamont (or Marchmont) Nedham. Nedham was a master of invective and one of the earliest to change sides when it suited him. From Oct. 1649 to June 1650, by a new act of parliament, the licensed press itself was entirely suppressed, and in 1649 two official journals were issued, *A Brief Relation* (up to Oct. 1650) and *Severall Proceedings in Parliament* (till Sept. 1655), a third licensed periodical, *A Perfect Diurnall* (till Sept. 1655), being added later in the year and a fourth, *Mercurius Politicus* (of which John Milton was the editor for a year or so and Nedham one of the principal writers), starting on June 13, 1650 (continuing till April 12, 1660). After the middle of 1650 there was a revival of some of the older licensed newsbooks; but the *Weekly Intelligence of the Commonwealth* (July 1650 to Sept. 1655) by R. Collings was the only important newcomer up to Sept. 1655, when Oliver Cromwell suppressed all such publications with the exception of *Mercurius Politicus* and the *Publick Intelligencer* (Oct. 1655 to April 1660), both being official and conducted by Nedham.

Till Cromwell's death (Sept. 3, 1658) Nedham reigned alone in the press, but in 1659 a rival appeared in Henry Muddiman (a great writer also of "newsletters"), whose *Parliamentary Intelligencer*, renamed the *Kingdom's Intelligencer* (till Aug. 1663), was supported by Gen. George Monk. Nedham's journalistic career came finally to an end (he died in 1678) at the hand of Monk's council of state in April 1660. His successor, Muddiman, was supplanted in 1663 by Sir Roger L'Estrange, formerly a royalist cavalry officer who narrowly escaped execution during the

Commonwealth; he was appointed "surveyor of the press." On him was conferred by royal grant—as it proved, for only a short period—"all the sole privilege of writing, printing and publishing all narratives, advertisements, mercuries, intelligencers, diurnals and other books of public intelligence; . . . with power to search for and seize the unlicensed and treasonable schismatical and scandalous books and papers." L'Estrange discontinued *Mercurius Politicus* and *Kingdom's Intelligencer* and substituted two papers, the *Intelligencer* (Aug. 1) and the *Newes* (Sept. 3), at a halfpenny, the former on Mondays and the latter on Thursdays; they were continued till Jan. 29, 1666.

3. The London Gazette.—The first number of the biweekly *Oxford Gazette*, licensed by Lord Arlington and written by Muddiman, was published on Nov. 16, 1665. With the publication of the 24th number (Monday, Feb. 5, 1666, old style) the *Oxford Gazette* became the *London Gazette*, which has appeared twice a week, on Tuesdays and Fridays, ever since as an official organ of the government. After the revolution of 1688 the press censorship was relaxed, being finally abandoned in 1693, and a number of newspapers came into being. *Worcester Post Man* (later *Berrow's Worcester Journal*) was the oldest of the provincial papers, having been founded in 1690. In 1699 appeared the *Edinburgh Gazette*, a biweekly. Elizabeth Mallet published the first English daily newspaper, *The Daily Courant*, on March 11, 1702. She abandoned the paper after the first nine issues but it was resumed a month later by Samuel Buckley.

4. The 18th Century.—Daniel Defoe was the first English journalistic writer of national importance. In Feb. 1704 he began his weekly, the *Review*, which eventually was printed three times a week and was a forerunner of the *Tatler* (started by Sir Richard Steele in 1709) and the *Spectator* (started by Steele and Joseph Addison in 1711). Defoe's *Review* came to an end in 1713, and between 1716 and 1720 he published a monthly with an old title, *Mercurius Politicus*.

The *Examiner*, started in 1710 as the chief Tory organ, enjoyed as its most influential contributor Jonathan Swift, the father of the leading article. Swift had control of the journal for 33 numbers between Nov. 1710 and June 1711, but on becoming dean of St. Patrick's he gave up regular journalistic work.

In 1696 Edward Lloyd—the virtual founder of the famous "Lloyd's" of commerce—started a thrice-a-week paper, *Lloyd's News*, which had but a brief existence in its first shape, but was the precursor of the modern *Lloyd's List*. No. 76 of the original paper contained a paragraph referring to the house of lords, for the appearance of which a public apology must, the publisher was told, be made. He preferred to discontinue his publication (Feb. 1697). In 1726 he in part revived it, under the title of *Lloyd's List*—published at first weekly, afterward twice a week. It later became a daily.

The increasing popularity and influence of the newspapers could not fail to be distasteful to the government of the day. The paper which seems to contain the first germ of the newspaper tax is still preserved among the treasury papers, and probably belongs to the year 1711. The duty eventually imposed (1712) was a halfpenny on papers of half a sheet or less, and a penny on such as ranged from half a sheet to a single sheet.

Swift's doubt, expressed in his *Journal to Stella* (Aug. 7, 1712), as to the ability of the *Spectator* to hold out against the tax was justified by its discontinuance in Dec. 1712, Steele starting the *Guardian* in 1713, which only ran for six months. But some of the worst journals that were already in existence kept their ground, and their number soon increased. Part of this increase may fairly be ascribed to political corruption. Later, toward the middle of the same century, the provisions and the penalties of the Stamp act were made more stringent. Yet the number of newspapers continued to rise. In 1753 the aggregate number of copies of newspapers annually sold in England, on an average of three years, amounted to 7,411,757. In 1760 it had risen to 9,464,790, and in 1767 to 11,300,980. In 1776 the number of newspapers published in London alone had increased to 53.

Thus the 18th century saw the gradual development of the purely political journal side by side with those papers which were primarily devoted to news, domestic and foreign, and commerce. It was left to Steele and Addison to develop the social side of journalism in their journals named above. Nor can Samuel Johnson's twopenny biweekly, the *Rambler*, started in 1750, and his weekly, the *Idler* (1758), be omitted. In 1762 the *North Briton* came out and it was largely as a result of John Wilkes's (*q.v.*) determined fight for the liberty of the press that at length the last shackles on free expression of opinion in Britain were cut away.

During the 18th century the epithet "grub street" for literary hackwork originated. According to Samuel Johnson's *Dictionary*, Grub street was "originally the name of a street near Moorfields, in London, much inhabited by writers of small histories, dictionaries, and temporary poems, hence any mean production is called *grubstreet*."

The outstanding daily paper in the middle of the 18th century was the *Public Advertiser*, which for about 25 years had been called the *General Advertiser* (and for some time the *London Daily Post*). It was published with notable success by Henry Woodfall and his son Henry Sampson Woodfall, and it was in this paper that the famous letters of Junius (*q.v.*) appeared. These papers led to a marked increase in its circulation, the monthly sale in Dec. 1771 being almost 84,000 as compared with 47,500 seven years previously. But in 1798 it was merged in the *Public Ledger*.

5. Early 19th Century.—In 1769 William Woodfall started the *Morning Chronicle*, whose daily circulation in 1819 reached 4,000, and in 1843, at a time when Charles Dickens was a contributor, 6,000. But in another six years the circulation had fallen to 3,000. For about five years it became the property of the duke of Newcastle, William Gladstone and others, but finally ended insolvent, after a life of more than 90 years. Another long-lived daily paper, whose top circulation was about 6,000, was the *Morning Herald* (1781–1869). It was William Cobbett who first attempted to reach the masses by his pen, and reduced the price of his *Weekly Political Register* from 1*s.* ½*d.* to twopence in his endeavour to appeal to the working classes for support of those principles of parliamentary reform dear to his heart. In 1808 Leigh Hunt brought out the *Examiner*, whose frank criticism of the prince regent landed him and a brother in prison.

The development of the press was enormously assisted by the gradual abolition of the "taxes on knowledge," and also by the introduction of a cheap postal system. In 1756 an additional halfpenny was added to the tax of 1712. In 1765 and in 1773 various restrictive regulations were imposed. In 1789 the three halfpence was increased to twopence, in 1798 to twopence-halfpenny in 1804 to threepence-halfpenny and in 1815 to fourpence, less a discount of 20%. As prosecutions multiplied, and the penalties became more serious, revolutionary tendencies increased in a still greater ratio. Blasphemy was added to sedition. Penny and halfpenny journals were established which dealt exclusively with narratives of gross vice and crime. Between 1831 and 1835 hundreds of unstamped newspapers made their appearance. The political tone of most of them was fiercely revolutionary. Prosecution followed prosecution, but all failed to suppress the obnoxious publications.

To Lord Lytton, the novelist and politician, and subsequently to Milner Gibson and Richard Cobden, is chiefly due the credit of grappling with this question in parliament to secure first the reduction of the tax to a penny in 1836, and then its total abolition in 1855. The number of newspapers established from the early part of 1855, when the repeal of the duty had become a certainty, and continuing in existence at the beginning of 1857, amounted to 107; 26 were metropolitan and 81 provincial. The duties on paper itself were finally abolished in 1861.

The abolition of the stamp taxes brought about such reductions in the prices of newspapers that they speedily began to reach the many instead of the few. Some idea of the extent of the tax on knowledge imposed in the early 19th century may be gathered from the fact that the number of stamps issued in 1820 was nearly 29,400,000, and the incidence of the advertisement tax fixed at 3*s.* 6*d.* in 1804, made it impossible for the newspaper owner to pass on the stamp tax to the advertiser. In 1828 the proprietors of *The Times* had to pay the state more than £68,000

in stamp and advertisement taxes and paper duty. But after the reduction of the stamp tax in 1836 the circulation of English newspapers rose from 39,000,000 to 122,000,000 in 1854.

6. The Growth of Parliamentary Reporting.—The first attempts to inform the public on what was being said and done in parliament were made by the *Gentlemen's Magazine* in 1736. As any reporting of the proceedings of the house was prohibited by a standing order of 1728, early reporters like Edward Cave (*q.v.*) could only take surreptitious notes; the published reports were written by another hand: by Dr. Johnson from 1740–43.

After a prosecution in 1771 the right of newspapers to publish parliamentary debates was never again challenged and early in the 19th century special galleries were provided for newspaper reporters. At first only *The Times* published full reports of the debates on the following day, but when the telegraphs were taken over by the state in 1870, the facilities for reporting were increased in every direction. News agencies began to supply identical accounts to provincial newspapers. Communications between the press gallery and the newspaper office were further developed when in 1951 *The Times* introduced remote-control typesetting of dispatches from the palace of Westminster.

7. London Morning Papers.—*The Times* was started by John Walter on Jan. 1, 1785, under the name of the *Daily Universal Register*. When it first appeared the *Register* was nothing more than a $2\frac{1}{2}d.$ broadsheet whose main function was to advertise an improved system of typography in which John Walter was interested and to give him cheap publicity for the books he published. On Jan. 1, 1788, its title was changed to *The Times*. It came into existence when free expression of opinion in the press was still a thing of the future, and within a few years of the establishment of his paper Walter had several sojourns in Newgate and had to pay several fines for criticisms of the authorities.

John Walter II practically took over the reins in 1803, and he also had to encounter the active opposition of governments which he had occasion to criticize, including that of William Pitt. He introduced a better system of news transmission and steam printing (1814), with the result that he was able to make the proud announcement that 1,100 sheets had been impressed in one hour. In view of the newspaper and advertisement tax and other disabilities, it was a considerable achievement when in 1815, the year of Waterloo, the daily circulation reached 5,000. In 20 years this was doubled, in 1851 it had reached 40,000 and three years later it was more than 50,000, when its most circulated rival, the *Morning Advertiser*, had a sale of fewer than 8,000 copies. When John Walter II assumed control *The Times* was a small four-page sheet; when he gave up control in 1847 it consisted of 12 large pages and the foundations of the paper's present reputation as the preeminent national journal and daily historical record were laid. John Stoddart, later governor of Malta, was editor until the end of 1816 when he resigned after a series of differences with John Walter II. He was succeeded in 1817 by the young Thomas Barnes, perhaps the greatest editor the paper has ever had, who had made his reputation as a critic and parliamentary reporter. When Barnes' health began to fail, much of the editorial work devolved upon Edward Sterling, whose pontifical and sometimes explosive style caused Thomas Carlyle to say: "He more than any other man was *The Times*, and thundered through it to the shaking of the spheres." It was, however, the *Morning Chronicle* in 1829 that first coined the popular description of *The Times* as the "thunderer."

In 1841, on the death of Barnes, the editorial chair was taken by John Thadeus Delane. In 1877 he was succeeded by Thomas Chenery, who died in 1884 and was followed by George Earle Buckle. Meanwhile, from 1848, John Walter III had been in command. He died in 1894, and was succeeded by Arthur Walter. At the beginning of the 20th century *The Times* began to feel the influence of the more go-ahead methods of the popular press, and there was a loss of circulation and revenue. It was a period when another great London daily paper, the *Standard*, was dying. Finally, in 1908, Lord Northcliffe realized his ambition and acquired control of the "Thunderer." He remodeled the organization and increased its efficiency. On his retirement Buckle was succeeded as editor by George Geoffrey Dawson. In 1919 he retired from the editorship because of a difference of opinion with Lord Northcliffe and his place was taken by Henry Wickham Steed, who died in 1956. In 1923 when, following the death of Lord Northcliffe, Maj. J. J. Astor, M.P. (later Lord Astor of Hever), became its chairman and chief proprietor, Dawson again became editor. Major Astor secured the future independence of the paper by a deed establishing a body of trustees consisting of holders of various public offices whose consent would be required to validate any future transfer of ownership. In 1941 Dawson retired from the editorship in favour of R. M. Barrington Ward who died seven years later and was succeeded by W. F. Casey. On his retirement in 1952 Sir William Haley, the then director-general of the British Broadcasting corporation, became the editor. With the issue of May 3, 1966, *The Times* broke tradition by devoting its front page to news instead of classified advertisements. The change brought a slight increase in circulation, to about 286,000, but not financial health. Money worries ceased later in the year when principal ownership of *The Times* was acquired by Lord Thomson of Fleet, proprietor of a worldwide chain of newspapers and magazines. He merged ownership of *The Times* and that of his flourishing *Sunday Times* (a paper that had no previous connection with *The Times*) in a new parent company, Times Newspapers, Ltd., under an arrangement that included four "independent national figures" on its board of directors. The editor of the *Sunday Times*, Denis Hamilton, became editor in chief of both papers, and Sir William Haley became chairman of the board.

The Times has always excelled in its home and foreign news departments and in mechanical production. On the editorial side it has at its command experts on every conceivable subject. From its earliest days it has maintained an able staff of correspondents in all the capitals of the world. Other publications issued from Printing House square, home of *The Times*, include the *Literary Supplement*; the *Educational Supplement*; the *Weekly Review*, first published in 1877 as the *Weekly Edition*; the monthly *Review of Industry and Technology*; and the bimonthly *Times Index*.

The *Daily Telegraph and Morning Post* was in the 1960s the second of the great national dailies and had a circulation of over 1,200,000. First published as the *Daily Telegraph and Courier* on June 29, 1855, it was owned by Col. Arthur B. Sleigh, who transferred it to Joseph Moses Levy in the following September. Levy produced it as the first penny newspaper in London, the name *Courier* being subsequently dropped. His son Edward Lawson (later the 1st Lord Burnham) soon became editor, which post he continued to hold till 1885. A long list of distinguished members of the staff included Sir Edwin Arnold, George Augustus Sala, Edward Dicey, Sir J. M. Le Sage, Bennet Burleigh, the war correspondent, J. L. Garvin and H. D. Traill; and among dramatic and literary critics Clement Scott, W. L. Courtney and W. A. Darlington. After 1890 Harry Lawson (later Viscount Burnham), eldest son of the owner, assisted in the general control. The repeal of the Stamp act in 1855 enabled the *Daily Telegraph* to challenge *The Times*. By 1861, only six years after it was started, it had a circulation of 130,000—more than double that of *The Times*—owing to its special appeal to the middle classes. It was consistently Liberal up to 1878 when it opposed Gladstone's foreign policy, and at the Irish Home Rule split in 1886 it became Unionist. Circulation by 1927, however, had declined to 84,000; and in 1928 Viscount Burnham sold the paper to Sir William Ewert Berry and Sir James Gomer Berry (later Viscount Camrose and Viscount Kemsley) and Sir Edward (later Lord) Iliffe. Circulation increased, doubling in 1930, when the price was reduced to a penny. The *Morning Post* was absorbed in 1937, and the *Daily Telegraph and Morning Post* was, in the early 1960s, a well-balanced morning newspaper, independent Conservative in politics.

The *Morning Post* had been founded in 1772 as the *Morning Post and Daily Advertising Pamphlet*, mostly an advertising sheet including state lotteries, then legal and popular. It developed into a national newspaper under the ownership of Peter and Daniel Stuart after 1795 and attracted a wonderful galaxy of writers, including Sir James Mackintosh, Samuel Taylor Coleridge, Robert Southey, Arthur Young, the poet Thomas Moore, William Words-

worth and Charles Lamb. The *Morning Post* maintained a tradition of vigorous and unblenching criticism, and Nicholas Byrne, editor-owner who succeeded Daniel Stuart, was murdered in his office as the result of an article which had given offense. In 1850 the paper came under the control of Peter Borthwick, and on his death in 1852 he was succeeded by his son Algernon (later Lord Glenesk). Among the editors of the *Morning Post* were Sir William Hardman, J. Nicol Dunn, Sir Fabian Ware and H. A. Gwynne. In 1937 the paper, as noted above, was consolidated with the *Daily Telegraph*.

The *Guardian* is the only example of a provincial paper that has acquired national standing. In 1960 the prefix "Manchester" was dropped from the title and two years later arrangements were made for the paper to be simultaneously printed in London and Manchester. Thus the *Guardian*, with a circulation in the early 1960s of 260,000, came to rival *The Times*. Founded as the *Manchester Guardian* in 1821, it was a weekly Whig organ and later became the chief exponent of Liberalism outside London. From 1872 to 1929 it was edited by C. P. Scott and gained a worldwide reputation. Apart from its vigorous politics it enjoyed an unrivaled literary prestige. It became a penny paper in 1857, two years after it had been turned into a daily.

Prominent names associated with it were C. P. Scott's son-in-law C. E. Montague, Leonard T. Hobhouse, Andrew Lang, Richard Jeffries, Richard Whiteing, Sir Claude Phillips, George Saintsbury, Laurence Housman, G. W. E. Russell, and Spenser Wilkinson. In its book reviewing, its dramatic criticism and its foreign correspondence the *Manchester Guardian* exercised an unparalleled influence in provincial journalism. The *Guardian* was helped by the prosperity of its evening associate, the *Manchester Evening News* (1868) acquired in 1924.

The *Daily Mail*, started by Alfred and Harold Harmsworth in 1896 as a halfpenny daily newspaper, was a phenomenal success from the first number. By 1900 it had already reached the 1,000,000 mark in circulation and by 1929 it had 2,000,000. In 1905 Sir Alfred Harmsworth started in Paris the *Continental Daily Mail*, later the property of Lord Rothermere. The *Daily Mail* also established editions in Manchester and Edinburgh. Sir Alfred Harmsworth (later Viscount Northcliffe) was not only a brilliant organizer but a keen journalist; he was the first to exploit the advantages of the short paragraph and introduced many other typographical features that are now standard practice in journalism. On his death in 1922, the paper came under the control of his brother, Lord Rothermere. On his retirement in 1937 the management passed to his son. In the late 1920s and early 1930s the *Daily Mail* had the largest daily circulation in the world. In the early 1960s its circulation of over 2,000,000, was exceeded by both the *Daily Express* and the *Daily Mirror*.

In 1960, the publishers of the *Daily Mail*, Associated Newspapers Ltd., purchased the *News Chronicle*. This paper was the result of the earlier amalgamation of several newspapers, notably the *Daily News* and the *Daily Chronicle*. The *Daily News* was founded in 1846 under the editorship of Charles Dickens. It became the champion of Liberalism, supporting the war of freedom in Italy and the emancipation of Bulgaria and the Armenians. Later it absorbed the *Morning Leader*, acquired the *Star* in 1909, absorbed the *Westminster Gazette* in 1928 and was amalgamated with the *Daily Chronicle* in 1930. The *Daily Chronicle* was established in 1877 and was turned into a general newspaper by Edward Lloyd, the founder of *Lloyd's News*. The paper reached a height of prosperity during World War I with Robert Donald as editor. The paper was owned by David Lloyd George for a brief period but in 1930 was amalgamated with the *Daily News* to form the *News Chronicle*. In 1955 it absorbed the *Daily Dispatch* of Manchester and at the time of its closure had a circulation of more than 1,500,000.

The *Daily Express*, which was founded as a halfpenny newspaper in 1900 by C. Arthur Pearson, passed the *Daily Mail* in circulation in the 1930s, partly through the use of free-gift inducements. Following the lead of U.S. newspapers, the *Daily Express* struck a new note of publishing its principal news on the front page. In 1904 R. D. Blumenfeld became editor and in 1912 he formed a syndicate which acquired control. Lord Beaverbrook began to take an interest in the paper while it was financially in low water, and in 1922 he obtained complete control. He spent prodigious sums in developing the paper, which in the early 1960s had 4,200,000 circulation and was being printed simultaneously in London, Manchester and Glasgow.

The *Daily Herald* was founded in 1912 as a Labour organ, but was not taken over officially by the Labour party until 1922. In 1929 Lord Southwood, head of Odhams Press Ltd., arranged to take a 51% interest, while the party retained 49%. It was agreed that the paper should support the policy of the Trades Union congress (T.U.C.). Shortly afterward the Labour party handed over its interest in the paper to the T.U.C. But in 1960 Odhams asked to be released from the agreement on the grounds that they could not make the paper pay unless they had complete editorial freedom. The T.U.C. agreed after Odhams had promised to "maintain the industrial and political integrity of the paper" and that it would continue as a "newspaper of the left." In 1961 control of the *Daily Herald*, together with the rest of Odhams Press, passed into the hands of the *Daily Mirror* group, later called the International Publishing corporation (I.P.C.). At that time the *Daily Herald* had a circulation of 1,400,000. In 1964 the I.P.C., having persuaded the T.U.C. to sell its interest for £75,000, produced a daily newspaper—the *Sun*—to replace the *Daily Herald*.

The *Daily Mirror* was originally issued in 1903 by Alfred Harmsworth as a woman's paper to be edited by women. When it did not succeed in this field, its owner soon made it into the first halfpenny illustrated tabloid. It retained a family flavour, however, with attention to women's interests. In the early 1960s it had the highest circulation of all the national dailies, selling 4,500,000 copies. The *Daily Sketch* was founded in 1909 as a halfpenny illustrated tabloid, absorbed the older and higher-priced *Daily Graphic* in the 1920s and was called for several years the *Daily Sketch and Graphic*. Coming into the hands of Lord Rothermere it was later sold by him to Lord Kemsley. The name of the *Graphic* was then dropped but in 1946 the *Daily Sketch* became the *Daily Graphic*. When, later on, it again passed into the control of Lord Rothermere, the title of the *Daily Sketch* was restored. In the early 1960s it had a circulation of 981,000.

Founded in 1930 as a Communist organ, the *Daily Worker* (renamed *Morning Star* in 1966) was suppressed in Jan. 1941 and did not appear again until Sept. 1942 when the U.S.S.R. had joined the war against Germany. Its circulation in the early 1960s was about 60,000.

8. London Evening Papers.—There are two evening papers published in London, the *Evening News* and the *Evening Standard*.

The *Evening News* was founded in 1881 and, after many vicissitudes, when in difficulty was acquired in 1895 by Alfred and Harold Harmsworth and Kennedy Jones. It was the Harmsworths' first incursion into daily journalism, and made a rich experimental field for the *Daily Mail*. One of the Associated Newspaper group, it had the largest circulation of any of the evening papers in the country in the early 1960s—approximately 1,458,000. In 1960 the group purchased the *Star*, which had been a London Liberal evening paper. It was started by T. P. O'Connor in 1888 as a halfpenny journal in support of Gladstone. In 1909 it was acquired by the *Daily News* and at the time of its demise had a circulation in excess of 1,000,000.

The *Evening Standard* was begun in the 1870s as the afternoon edition of the *Standard* (*see* below) and was devoted largely to commercial news. In 1923 it became the property of Lord Beaverbrook, and later it absorbed the famous old *Pall Mall Gazette* (*see* below). Often called a "quality" evening newspaper, it had a circulation of nearly 800,000 early in the 1960s.

9. Great Papers of the Past.—Fleet street is peopled with the ghosts of journals which in their time filled important places in the life of the country. There was the *Morning Chronicle*, which began its career in 1769 and had among its leading contributors R. B. Sheridan, Sir J. Mackintosh, John Campbell (afterward lord chancellor), the poet Thomas Campbell, Thomas Moore, Lord Brougham, Byron, William Hazlitt, J. S. Mill, Charles Lamb and W. M. Thackeray. John Black was its most famous editor. After

a notable career the *Morning Chronicle* died in 1862.

The *Standard* was established as an evening paper in the Tory interest in 1827. In the 1850s it was purchased by James Johnstone, who brought out the *Standard* as a morning paper (1857). One of its contributors in the 1860s was Lord Robert Cecil, later Lord Salisbury. Johnstone, to whose energy and perspicacity the paper owed so much, died in 1878, and under his will William H. Mudford was appointed editor and manager for life, or until resignation. In Mudford's hands the *Standard* entered upon a successful period. It had many famous war correspondents, foremost among whom were G. A. Henty, John A. Cameron and William Maxwell. In Jan. 1900 Mudford was succeeded by G. Byron Curtis (d. 1907). In Nov. 1904 the *Standard* was sold to Sir Arthur Pearson. In 1910 it passed into the control of Davison (later Lord) Dalziel and disappeared during World War I.

A disastrous experiment in newspaper production was the *Tribune*, founded by Franklin Thomasson in 1906 as a solid penny daily. After gathering a brilliant staff and expending very large sums he discontinued the paper in 1908. The unhappy enterprise was described in Sir Philip Gibbs's novel *The Street of Adventure*.

The first number of the *Pall Mall Gazette* (the name being borrowed from the incident in which Thackeray describes Captain Shandon in the Marshalsea prison drafting the prospectus of the *Pall Mall Gazette* as a paper "written by gentlemen for gentlemen") appeared in Feb. 1865. Its first editor was Frederick Greenwood, who gathered round him a brilliant array of talent in Sir Henry Maine, Sir J. Fitzjames Stephen, Anthony Trollope, Charles Reade, George Henry Lewes, George Eliot, Matthew Arnold and Richard Jefferies. In 1875 Greenwood was able to convey to Disraeli news of the French bid to secure control of the Suez canal, thereby enabling Britain to get in first. It had been a consistent supporter of Disraeli, and when on changing hands it became Liberal, John Morley (later Viscount Morley of Blackburn) became editor, with William T. Stead as assistant editor. When Morley exchanged journalism for politics in 1883, he was succeeded by Stead. Stead was succeeded by E. T. Cook in 1889. The *Pall Mall Gazette* was now steadily Liberal and a strong advocate of Irish Home Rule. Two distinguished editors at a later date were Sir Douglas Straight and J. L. Garvin. It was consolidated with the *Evening Standard* in 1925.

Founded in 1880 by H. Hucks Gibbs (later Lord Aldenham) for Frederick Greenwood to edit when he had left the *Pall Mall Gazette*, the *St. James's Gazette* represented the more intellectual and literary side of Tory journalism in opposition to the new liberalism of Greenwood's former organ. In 1888, the paper having been sold, Greenwood retired and was succeeded as editor (1888–97) by Sir Sidney Low, who in his turn was succeeded by Hugh Chisholm (1897–99). Among the contributors were Rudyard Kipling, Sir James Barrie and G. S. Street. Toward the end of the 19th century it assumed a more popular style and shape, and for a year or two before its acquisition by Pearson in 1903 and its final merging in the *Evening Standard* it was edited by Ronald McNeill (later Lord Cushendun).

When the *Pall Mall Gazette* was sold to Lord Astor in 1892 and converted into a Conservative organ, E. T. Cook, the editor, and most of his staff resigned; in 1893 they came together again on the *Westminster Gazette*, newly started for the purpose by Sir G. Newnes as a penny Liberal evening paper. The paper was conducted on the lines of the old *Pall Mall Gazette*, and it had the advantage of a brilliant political cartoonist in Sir Carruthers Gould. In 1896 Cook was appointed editor of the *Daily News*, and his place was ably filled by J. A. Spender. The *Westminster Gazette* became conspicuous for its high standard of political and literary criticism, and gradually became the chief organ of Liberal thought in London. In 1908 it was sold to a group of Liberal capitalists. After World War I it was replaced by a daily newspaper of the same name which was merged in the *Daily News* in 1928.

10. Provincial Press.—The first provincial paper in England was the weekly *Worcester Post Man* (1690), later the modern *Berrow's Worcester Journal*. In the first 20 years of the 18th century a number of other, mainly weekly, journals sprang up in country towns, among them the *Stamford Mercury* begun in 1713 and the *Northampton Mercury* begun in 1720. At the start of the 19th century the provincial press consisted of fewer than 100 journals, practically without influence. Benjamin Flower, printer of the *Cambridge Intelligencer*, was the first to introduce the leading article in the provincial press. The *Leeds Mercury*, founded in 1717, under the control of Edward Baines (1801) became the most important and influential of the north country papers in the first half of the 19th century. After the Reform act of 1830, the spread of self-education and the establishment of reading circles and newspaper clubs, the country newspapers developed in importance and usefulness. It was not, however, till the final removal of the taxes on knowledge that the provincial press came into its own.

Within ten years of the abolition of the paper duty, penny morning newspapers had taken up commanding positions in many cities in England, Scotland and Ireland. But any real importance as organs of opinion was still confined to only a few of the great penny provincial dailies, notably the *Yorkshire Post*, *Manchester Guardian*, *Birmingham Post* (1857), *Sheffield Telegraph* (associated with Sir W. Leng), *Liverpool Daily Post*, *Leeds Mercury* and *Western Morning News;* others were at the same time cradling journalists who were to become famous, such as the *Darlington Northern Echo*, on which W. T. Stead made his debut.

The first syndicate to send out war correspondents was formed by the *Glasgow News*, *Liverpool Daily Post*, *Manchester Courier*, *Birmingham Gazette* and *Western Morning News*, which dispatched two correspondents to Egypt. The Central News also sent out war correspondents to Egypt and the Sudan. During the South African War (1899–1902) the leading provincial newspapers, however, all formed syndicates to secure war telegrams.

The following were the leading English provincial daily papers in the early 1960s:

The *Yorkshire Post* began in 1754 and became the principal Conservative newspaper outside London, enjoying national prestige extending far beyond the borders of Yorkshire. In its early years it devoted especial attention to racing, which was neglected by most local papers in the country in those days, and under the control of the Beckett family it rapidly attained a solid prosperity. It had talented editors in H. J. Palmer, J. S. R. Phillips, Arthur H. Mann and Sir Linton Andrews.

The *Yorkshire Evening Post*, founded 1890, became the popular evening paper for all Yorkshire, with a circulation of 236,000.

The *Birmingham Daily Post* was founded in 1857 by J. F. Feeney and John Jaffray and later was controlled by Sir Charles Hyde. It came to hold a position in the midlands analogous to that of the *Yorkshire Post* in the north. It was purchased by Lord Iliffe after Hyde's death in 1942. Its evening associate, the *Birmingham Mail*, had a circulation of 294,000 in the early 1960s. In 1956 the group absorbed the *Birmingham Gazette*.

The *Liverpool Daily Post* was founded in 1855 as a Liberal paper. In 1904 it absorbed the *Liverpool Mercury* (founded in 1811), and it assumed a pre-eminent place in the life of the great seaport. It was far exceeded in circulation by its afternoon associate, the *Evening Echo*, with a circulation of 410,000.

11. Scotland, Wales and Ireland.—In Scotland the leading newspapers in the 1960s were still *The Scotsman* and the *Glasgow Herald*. The former was started as a biweekly in 1817 and became a daily in 1855. It was Liberal until the Home Rule split in 1886 when it adopted the Unionist cause. Alexander Russel was its most famous editor in the 19th century (1848–76) and worthy successors included Sir George Waters and J. Murray Watson. For many years it has been the only Edinburgh morning newspaper, and in 1959 was acquired by Roy Thomson from its former owner, Lord Kemsley. The *Glasgow Herald* dates from 1783, when it first came out with the extra name *and Advertiser*. It acquired a great literary reputation under an illustrious line of editors, including Samuel Hunter, George Outram, Sir Robert Bruce and Sir William Robieson.

The largest circulations in Scotland in the early 1960s were both achieved by papers owned by the International Publishing corporation; the *Sunday Mail* with 612,000 and the *Glasgow Daily Record* with 500,000.

In Wales the four Cardiff papers in 1929 were amalgamated into two, the *South Wales Echo* and the *Western Mail*, both Thomson newspapers; in the early 1960s the former had the largest of Welsh circulations—about 150,000. In 1929 also the two Swansea papers were consolidated by the Northcliffe newspaper group as the *South Wales Evening Post*.

In Northern Ireland, Belfast had three morning papers and one evening paper in 1963. The morning papers were the *Belfast News-Letter* (1737), the *Northern Whig* (1824) and the *Irish News* (1855). The evening paper was the *Belfast Telegraph* (1870). In Ireland three morning and two evening papers were published at Dublin and one of each at Cork. Largest of these was the *Irish Independent* and oldest was the *Cork Examiner* (1840, morning). There were also two local Sunday papers.

See also *Newspaper Chains*, below.

12. British Illustrated Newspapers.—English papers carried news pictures as early as 1731, when the *Grub Street Journal* printed a woodcut depicting the lord mayor's show, but not until 1842 did England have a fully illustrated newspaper.

Herbert Ingram brought out the first number of the weekly *Illustrated London News* on May 14, 1842. It contained 16 printed pages and 32 woodcuts. The chief engravings, by Sir John Gilbert, illustrated the first *bal masqué* given by Queen Victoria at Buckingham palace. Control of the paper passed in 1860 to Ingram's son, later Sir William Ingram. Its editors included Charles Mackay (1848–59), John Lash Latey (1859–90) and Clement K. Shorter (1890–99). In 1861 the first penny popular paper was started by the same proprietor, the *Penny Illustrated Paper*, edited by John Latey, Jr., who afterward was editor of the *Illustrated London News*. In 1869 the first serious rival of the *Illustrated London News* was published, the *Graphic*, produced by W. L. Thomas. *Black and White*, a paper of the same class as the *Illustrated London News*, followed in 1891; and in 1892 the *Sketch* was started by Sir William Ingram, under the editorship of Shorter, as a social and theatrical illustrated weekly.

From this time forward, many illustrated weeklies were started in the fields of the theatre, sports, fashion and society. Perhaps the most successful of all illustrated newspapers was *Picture Post*. It was started by Sir Edward Hulton in 1938 and ten years later had achieved a circulation of 1,400,000; by the time it closed in 1957 this figure had dropped by half. The owner attributed its collapse not so much to television as to a general change in reading habits. A year later Odhams' *Illustrated* whose circulation (at one time over 1,000,000) had suffered a similar decline also disappeared. The *Illustrated London News*, however, survived all these changes although its parent company, Illustrated Newspapers Ltd., had a number of owners over the years. It was created in 1926 by William Harrison, purchased in 1937 by Sir John Ellerman and Lord Southwood and changed hands again when Roy Thomson bought it in 1961.

13. Sunday Newspapers.—The *Observer*, the oldest of the Sunday newspapers, was founded in 1791. It kept on its respectable but somewhat sombre career until it was acquired by Lord Astor and edited by J. L. Garvin, when it assumed a distinctive character—a virile independence in its political outlook while making a strong feature of foreign correspondence, literature, the drama, etc. On Garvin's resignation in 1942 he was succeeded by David Astor. In 1964 its circulation was 716,000.

The *Sunday Times* was founded in 1822. Its course was similar to that of the *Observer* until 1915, when it was acquired by William and James Berry. The former was editor in chief of the *Sunday Times*, 1915–37. In 1959 the paper was bought from Lord Kemsley by Roy Thomson (later Lord Thomson of Fleet) but retained its conservative character. The feature side of the paper was expanded, the most notable development being the introduction of a colour section in 1962. Its circulation was about 1,360,000 in 1966, when it was merged with *The Times* (*see* above, *London Morning Papers*).

In 1961 the *Sunday Telegraph* came to join the *Observer* and the *Sunday Times* in the "quality" field. Launched by the *Daily Telegraph* it is, like its parent, an independent Conservative paper with a circulation of approximately 700,000.

The best-selling Sunday newspaper in the early 1960s was the *News of the World* (founded 1843), which devoted considerable space to sport and crime. Sir Emsley Carr was editor for half a century from 1891 until his death in 1941. The paper passed the 1,000,000 mark shortly after 1900 and by the early 1960s had a circulation of well over 6,484,000, being the largest newspaper in the free world. In 1960 the publishers acquired the *Empire News* (2,000,000), founded in Manchester in 1884.

The *People*, with a circulation in the early 1960s of over 5,500,000, was printed in London and Manchester, as was the *News of the World*. Founded in 1881, it was acquired by the *Daily Mirror* group in 1961 when it gained control of the former publishers, Odhams press. The *Sunday Express*, founded in 1918 as the Sunday edition of the *Daily Express*, sold about 4,333,000 copies. The *Sunday Dispatch*, founded in 1801 as the *Weekly Dispatch* and later affiliated with the *Daily Mail*, closed down in 1961; the *Sunday Graphic* established in 1915 closed down in 1960. *Reynolds News* (1850), the organ of the co-operative movement (circulation 361,000), changed its name in 1962 to the *Sunday Citizen*. The *Sunday Pictorial* (1915) had a circulation of more than 5,000,000 in 1964 when the name was changed to the *Sunday Mirror*.

14. Competition for Mass Circulation.—The competition for circulation reached its height between World Wars I and II and the popular newspapers resorted to many unusual expedients. Free insurance policies were offered to readers and their families and, in return for a subscription to the newspaper, the citizen could obtain free gifts which ranged from complete sets of books by well-known authors to washing machines. Crossword and other competitions for which substantial prizes were awarded were introduced. The result was that for a time circulations were artificially inflated and it is to be doubted whether the public read all the newspapers for which it paid subscriptions. The newspapers realized that a disaster, if it caused the deaths of many policyholders might have a crippling effect on their finances and a mutual arrangement was agreed upon to limit this form of artificial circulation. In World War II canvassing for circulation was forbidden and circulations were frozen at 1939 levels. There was, however, a renewal of some of this competition during the 1950s when inducements to purchase newspapers included gifts ranging from a racehorse to a public house. This practice is now forbidden by agreements between the national newspapers. The coming of broadcasting and television stimulated interest in news, and circulations of daily papers continued to mount steadily.

This increase in the circulation of individual newspapers was accompanied by a decline in their total numbers. Between 1953–63, 18 papers disappeared, either ceasing entirely or being absorbed by other publications. It is a feature of the British newspaper industry that the fortunes of any one newspaper are governed as much by the success or failure of its immediate competitors as they are by the skill and efficiency of its staff.

Most British newspapers gain the majority of their income, not from sales, but from advertising. As advertisers place their business where they know they can get the best value for money and as there is a limited amount of advertising to go round the paper with a relatively small circulation inevitably loses ground to its more powerful competitor; it is generally assumed that for a paper to remain viable in the 1960s it has to command a circulation which is at least half that of the most successful paper in its field. It was this situation that led to the closure of the *News Chronicle* (1,500,000) in 1960, killed by competition from such papers as the *Daily Express* (4,200,000) combined with rising production costs which cut profit margins to the minimum. The circulations of *The Times* and the *Guardian* were infinitely smaller but because their readers were drawn from the more affluent and influential sections of the community, companies with capital rather than consumer goods to sell were willing to pay their relatively high advertisement rates.

15. Newspaper Chains.—The second development that marked the period 1950–61 was the increasing concentration of the ownership of newspapers into fewer and fewer hands. In 1948 the three leading chains, Beaverbrook Newspapers Ltd., Associated

Newspapers Ltd. and the *Daily Mirror-Sunday Pictorial* group, controlled 43% of the total circulation of all daily and Sunday newspapers. By 1961 these combines had 65% of that circulation. The Westminster Press Provincial Newspapers, Ltd., owned 61 of the provincial papers in 1962, over two-thirds of the total number. In the early 1960s there was no town in England and Wales with more than one locally published morning paper and in only four towns outside London was there more than one evening newspaper.

16. Censorship.—With the outbreak of World War II the newspapers were brought under a system of voluntary censorship which had been worked out in advance by a committee representing the services and other government departments and the press. On the whole the system worked well, although in the early months there were some irritating delays and restrictions which were gradually smoothed out. No newspaper was compelled to submit its copy to the censorship department unless a definite embargo had been imposed upon a particular item of news. Comment was not restricted. The newspapers loyally accepted the system and any news which it was felt might give information to the enemy was submitted, for the newspapers realized that the fact that the copy had been passed by the censorship department would be a great help to them if, by any chance, proceedings were brought under the Official Secrets act. Contact between the government and the press was maintained by a system of defense notices and at the end of the war it was agreed that this machinery should be kept in being in case it might be needed again. During the war there were suggestions that the government was contemplating compulsory censorship but the idea was resisted vigorously by the newspapers.

17. The Royal Commissions on the Press.—In the years that followed the end of World War II controversy about the growing power of the newspaper chains and criticism about the alleged bad behaviour of a few individual journalists led to the setting up in 1947 of a royal commission which was charged "to inquire into the control, management and ownership of the newspaper and periodical Press and news agencies." In its report the commission decided "there was nothing approaching a monopoly in the press as a whole." It recommended the establishment of a general council of the press to safeguard the freedom of the press and to encourage a sense of public responsibility among journalists. In July 1953 a voluntary press council was established by seven organizations representing the proprietors, editors and working journalists. In 1963, acting on recommendation of the second royal commission (*see* below), the press council reformed its constitution. Its members were no longer entirely drawn from the profession; it was now headed by an independent chairman and 20% of its members were laymen.

In 1961, following the merger of Odhams and the *Daily Mirror-Sunday Pictorial* group, the government appointed a second royal commission to "examine the economic and financial factors affecting the production and sale of newspapers, magazines and other periodicals"; in particular they were to report whether the manufacturing and other costs, the efficiency of production and the advertising revenue (including that derived from television interests) tended to "diminish diversity of ownership and control or the number or variety of such publications, having regard to the importance, in the public interest, of the accurate presentation of news and the free expression of opinion."

A year later the commission reported that it had found "spectacular" movements toward concentration of ownership had taken place among periodicals and that the extent to which a few proprietors dominated the actual supply of news and opinion through the daily and Sunday press had greatly increased. The commission believed there was still a considerable range of choice in the national daily and Sunday press but the concentration of ownership carried with it the potential danger that variety of opinion might be stifled. It recommended that any acquisition by a purchaser who had, or who would acquire as the result of a transaction, the controlling interest of daily or Sunday newspapers with aggregate circulations exceeding 3,000,000 copies should come under the jurisdiction of a Press Amalgamation court whose consent would only be given if it could be established that such a transaction was not contrary to the public interest.

III. GERMANY

It appears that not only was the first western printing from movable type done in Germany, but some of the earliest news pamphlets and perhaps the first regularly published newspapers were issued there. At any rate, there is a file of the *Avisa Relation oder Zeitung*, published at Augsburg in 1609, and one copy of the Strasbourg *Relation* of that year.

These papers were followed by others, such as the *Frankfurter Journal* of Egenolph Emmel in 1615 and the *Frankfurter Oberpostamtszeitung*, begun in 1616 and continued until 1866 under the shortened title of *Postzeitung*. In the course of the 17th century, most German cities supported newspapers; in the 18th century, despite the rigours of local and state censorship, the press multiplied throughout the country. Notable for its correspondence from abroad was the *Hamburgischer Correspondent*, founded in 1714 under the title *Holsteinische Zeitungs-Correspondenz*. The outstanding Berlin papers in the 18th century were two named, for their owners, *Vossische Zeitung* (1705) and *Spener'sche Zeitung* (1749); the latter was renamed *Berlinische Nachrichten* and lived until 1827. Under Napoleon censorship merely changed hands; the German press became Gallic and the newspapers echoes of the Parisian journals. But when Germany was liberated the old censorship reappeared. An 1819 resolution of the diet subjected the press to police supervision.

The greatest German newspaper in the first half of the 19th century was the *Allgemeine Zeitung*. It was founded at Tübingen by Johann Friedrich Cotta (later Baron von Cottendorf) in 1798. Censorship and other causes forced it to move successively to Stuttgart, Ulm, Augsburg and Munich. The revolutionary movements of 1830 and 1848 gave impetus to a new German journalism which, though most of the papers were short lived, brought in a new period of press enterprise. Many small papers were established throughout Germany and Austria, nearly all of them consistently partisan. Censorship varied in different states. Those best known throughout the nation, besides the *Allgemeine Zeitung*, were the *Augsburger Zeitung* (1689) and the *Kölnische Zeitung* (1804).

Bismarck had a high respect for the power of the press and kept a firm hand on its control. The press law under which the German newspapers operated 1874–1919 "guaranteed" freedom of the press but actually retained strong government controls. Even during World War I the government controlled a number of important newspapers. Following that war, besides owning Wolff's Telegraphic bureau, the leading news-gathering agency, the Prussian government secretly bought the *Deutsche Allgemeine Zeitung*, a Berlin paper founded in 1921 by Hugo Stinnes, and later sold it to the government of the *Reich*.

1. Under the German Republic.—Under the Weimar constitution of 1919, German newspapers enjoyed more freedom than they had ever known. In the years 1919–32 the *Gruppenpresse* (newspapers representing political, social and religious groups), though composed of papers of small individual circulations, maintained dominance in the country's journalism. During the 1920s, however, a *Massenpresse*, composed of large-circulation dailies designed for the masses rather than for parties or factions, grew up in Berlin and other large cities; these papers, though more objective in reporting and comment, were commonly partisan in control and thus had notable alignments with the *Gruppenpresse*.

By 1932 there were 4,700 newspapers in Germany, 70% of them dailies. More than 100 different parties or group ideologies were represented. The largest paper in this period was the *Berliner Morgenpost*, claiming 600,000 in 1932. It was founded in 1898 by the "house of Ullstein," which consisted of Leopold Ullstein and his five sons. The father had entered the newspaper field by purchasing the *Berliner Zeitung* in 1877 (later called *BZ am Mittag* and credited with 190,000 circulation in 1932). Other Ullstein dailies were the old "quality" *Vossische Zeitung*, acquired in 1913,

never a circulation leader; and *Tempo*, an evening paper started in 1930, which had 140,000 by 1932. Other large papers in Berlin were *Der Tag* (1900), claiming 100,000 in 1932; and *Berliner Nachtausgabe* (1924), with 180,000. These, with the *Lokalanzeiger*, were Scherl papers, backed by the Hugenberg *Konzern*. Alfred Hugenberg, leader of the Nationalist party, controlled the large Scherl dailies, as well as the weeklies and magazines of that chain. Besides the Ullstein and Hugenberg combines, Konzentrations A.G. controlled about 200 Social-Democratic papers and owned a news agency; Rudolph Mosse controlled the *Berliner Tageblatt, Volkszeitung* and *Morgenzeitung* in Berlin.

A number of large papers, regarded as belonging to the *Massenpresse* because they each had 100,000 circulation or more, had by 1932 grown up in other large cities besides Berlin. But some of the most influential papers in Germany had only about 60,000 circulation, such as *Frankfurter Zeitung* (1856), *Kölnische Zeitung, Nuremberg Fränkische Kurier* (1833) and *Hamburger Nachrichten* (1792). This quartette of famous old papers was long powerful in Europe. Oldest of all German papers, with only a few thousand circulation in 1932, was the *Hartungsche Zeitung* of Königsberg (1640).

2. The Hitler-Goebbels Press.—Adolf Hitler's first task in connection with the group which was soon to become the National Socialist party was the direction of a press and news bureau in the district army command at Munich in 1919. After the military *Putsch* of March 1920, sympathizers bought for Hitler the *Völkischer Beobachter*, which had been founded several years before World War I as a weekly gossip sheet. As the Nazi influence expanded in the 1920s, its newspaper effort broadened; but the *Beobachter* remained Hitler's personal organ, and for the elections of 1932 he established a Berlin edition. In connection with those elections, also, Hitler's party established or acquired about 130 other newspapers distributed throughout Germany.

When Hitler became chancellor in Jan. 1933, he immediately caused Pres. Paul von Hindenburg to invoke article 48 of the constitution in order to cancel the guarantee of freedom of the press. Some papers were stopped at once, and the press in general was muzzled. Within three months 200 papers had been suspended, including the venerable *Vossische Zeitung;* within a year 600 had been killed, the Deutsche Nachrichtenbüro (DNB) had been set up to supersede Wolff's Telegraphic bureau, and a journalists' registration system had been devised which made newspapermen "semiofficial public functionaries." Max Amman, publisher of the *Völkischer Beobachter*, became president of the *Reich* press chamber, a division of Josef Goebbels' ministry of public enlightenment and propaganda. Goebbels had founded the newspaper *Der Angriff* in 1927 and two years later became head of Nazi propaganda activities. Amman's duties were largely on the business side, though he shared with Otto Dietrich the veto on new papers. Dietrich was *Reich* press chief and had charge of editorial policies and personnel. Eher Verlag was set up to handle Nazi printing and publishing; operating chiefly in Berlin and Munich, it soon became the largest publishing concern in the world. It published the *Beobachter, Angriff, Schwarze Korps* (SS organ), *Arbeitsmann, Hitlerjugend* and other official newspapers and periodicals, as well as books and pamphlets.

Jewish newspaper owners—the Ullsteins, Mosse, etc.—were driven out. When Germany seized Austria in 1938 many of the old papers (including *Wiener Zeitung*, founded in 1703) disappeared, and the remainder of the Vienna papers were combined in one Nazi organ. The number of newspapers in Germany was reduced from 4,700 in 1932 to about 2,000, and the press became, to use Goebbels' famous figure, an organ on which the minister of propaganda could play his own tunes.

3. The Occupation Press.—World War II annihilated the German press. New papers were licensed by the occupation powers in their various zones. The Soviet military government established *Tägliche Rundschau* in Berlin; the U.S. military government set up *Die Neue Zeitung* in Munich; the British founded *Die Welt* in Hamburg; the French licensed *Der Kurier*, an afternoon Berlin paper. By mid-century there were 20 dailies in Berlin, of which the Soviet *Rundschau* had the largest circulation, said to be 800,000; while the British-licensed *Telegraf* and the U.S.-licensed *Tagesspiegel* each had around 500,000. The U.S. semiweekly *Neue Zeitung* was circulating more than 2,300,000 copies of each issue including Berlin and Frankfurt editions; and the British triweekly *Die Welt*, 700,000, also including a Berlin edition. Most papers outside Berlin were published only two or three times a week.

4. German Federal Republic and Western Berlin.—There were important developments in the press after the foundation of the German Federal Republic in Sept. 1949. The system of licences was abolished and a return made to free competition. Some newspapers founded by the occupation authorities disappeared (*Neue Zeitung*); others continued their existence as wholly independent undertakings (*Die Welt*); new journals were started or old ones reappeared (*Berliner Morgenpost* and *BZ* launched in western Berlin by the Ullstein group). In the early 1960s there were 535 dailies, many of them with subsidiary editions, with a circulation of over 15,700,000 and 13 weeklies with a circulation of 2,600,000. The provincial press increased greatly. Several hundred newspapers used the special articles supplied by a small number of centralized agencies (*Maternpresse*). Another characteristic of the postwar daily press was the reduction in the number of papers affiliated to political parties (about 10%).

In the early 1960s in the Federal Republic the highest circulation was held by *Bild-Zeitung* in Hamburg (3,716,200) followed by the *Westdeutsche Allgemeine Zeitung* of Essen (422,000). Among the most important papers by reason of their circulation or influence were the *Kölnische Rundschau* (Cologne), *Süddeutsche Zeitung* (Munich), *Die Welt* and *Hamburger Abendblatt* (Hamburg), *Stuttgarter Zeitung* (Stuttgart) and the dailies of Frankfurt, which became the centre of German journalism after World War II: *Frankfurter Allgemeine, Frankfurter Neue Presse* and *Frankfurter Rundschau.*

In western Berlin the highest circulation record was held by the dailies *Berliner Morgenpost* and *BZ*, both of which exceeded 200,000 circulation, while quality papers remained, notably *Der Taggesspiegel* and *Telegraf.*

In 1949 the national agency Deutsche Presse-Agentur (D.P.A.) was started with headquarters in Hamburg. It very soon became one of the largest in Europe.

5. German Democratic Republic.—After the proclamation of the German Democratic Republic in Oct. 1949, the press underwent a considerable change. Although the system of licensing permitted by the occupying power theoretically disappeared, strict supervision persisted but it was exercised by the *Presseamt* which itself received instructions from the Politburo of the Socialist (Communist) Unity party or S.E.D. Only the *Tägliche Rundschau* continued to be edited by the Soviet military commander, but it stopped publication in 1955.

In 1953 the authorities suspended the big circulation evening paper *Nacht-Express* which had been trying since 1945 to keep its public objectively informed.

In the early 1960s there were 39 dailies in the Democratic Republic. Largest was the *Neues Deutschland*, main organ of the S.E.D., with a circulation of about 500,000, while 60% of the other papers belonged to the S.E.D. party press. Total circulation for the country did not exceed 4,000,000. In East Berlin nine daily newspapers were published.

The agency Allgemeiner Deutscher Nachrichtendienst (A.D.N.) founded in 1946 and nationalized in 1953, had a monopoly.

IV. FRANCE

The French newspaper press from the first was characterized by a literary quality generally superior to that of the press of most other countries, by special attention to the arts and by alliances (sometimes amounting to subsidization) with political, social or literary groups. Parisian journalism frequently became a path to fame in both politics and literature.

1. Beginnings.—The first French newspaper was the *Gazette* (afterward called the *Gazette de France*), established in 1631 under the patronage and with the active co-operation of Cardinal Richelieu. The first editor and printer was Théophraste Renaudot. The first weekly number apparently appeared in May 1631.

much, at least, may be inferred from the date (July 4, 1631) of the sixth number, which was the first dated publication. Each number of the paper, which cost six centimes, consisted of a single sheet (eight pages) in small quarto, and was divided into two parts—the first simply entitled *Gazette*, the second *Nouvelles ordinaires de divers endroits*. It commonly began with foreign and ended with home news. Much of its earliest foreign news came direct from the minister, and often in his own hand.

In 1672 the *Mercure galant* was established by Donneau de Vizé. Its title was later changed to *Nouveau Mercure*, and in 1728 to *Mercure de France*, a designation retained, with slight modification, until 1853, when the paper finally ceased. It had many prominent contributors. In 1790 its circulation rose very rapidly and reached for a time 13,000 copies. Under Napoleon the organ of official information was the *Moniteur* (*Gazette nationale, ou le moniteur universel*), founded in 1789 under the same general management with the *Mercure*. The *Moniteur* kept step with the majority of the assembly, the *Mercure* with the minority.

The only other newspaper of a date anterior to the Revolution which need be noticed here is the first French daily, the *Journal de Paris*, which was started on New Year's day of 1777 and lived till 1819. Its period of highest prosperity may be dated about 1792, when its circulation is said to have exceeded 20,000. The *Journal des débats* was founded in 1789 by François Jean Baudouin and lasted until the beginning of World War II.

2. The 19th Century.—The cheap journalism of Paris began in 1836 with the journal of Émile de Girardin, *La Presse*, and *Le Siècle*, under the management of Dutacq, to whom, it is said—not incredibly—the original idea was really due. The first-named journal attained a circulation of 10,000 copies within three months and soon doubled that number. The *Siècle* prospered even more strikingly, and in a few years had reached a circulation (then without precedent in France) of 38,000 copies.

On July 16, 1850, the assembly passed what is called the *loi Tinguy* (from the name of the otherwise obscure deputy who proposed it), by which the author of every newspaper article on any subject, political, philosophical or religious, was bound to affix his name to it, on penalty of a fine of 500 fr. for the first offense and of 1,000 fr. for its repetition. Every false or feigned signature was to be punished by a fine of 1,000 fr., "together with six months' imprisonment, both for the author and the editor." The practical working of this law lay in the creation of a new functionary in the more important newspaper offices, who was called *secrétaire de la rédaction*, and was, in fact, the scapegoat ex officio. The *loi Tinguy* had a permanent influence on French journalism in the continued prevalence of signed articles, and the consequent prominence of individual writers as compared with the same class of work in other countries.

Moïse Polydore Millaud, creator of the French halfpenny press, made a fortune from *Le Petit Journal* and introduced a new era of cheap papers. In 1878 the paper had a circulation of about 650,000 compared with the circulation of *Le Figaro* (1826) of 70,000. At that period the total number of journals of all kinds in France was 2,200.

The newspapers of Paris, and similarly of France, practically doubled in number between 1880 and 1900. In 1880 there were about 120 Paris newspapers, in 1890 about 160 and in 1900 about 240. The total number of newspapers, as distinguished from periodicals, published in France during 1900 was 2,400, of which about 2,160 appeared in 540 provincial towns.

The French papers, of whatever party, took an increased interest during this period in foreign matters and much improved their organization for collecting news. *L'Eclair* gave less attention to the discussion of political questions from the party point of view than to the collection of news, and was followed by the *Echo de Paris* (1884) and *Le Matin*, which also dated from 1884, and which by an arrangement with the *Times* of London gave every day a translation of most of the telegrams published in that newspaper. The *journal d'information*, as these papers were called, took its place beside the *journal d'opinion*, more perhaps as a rival than as a complement. The natural result followed, and the more old-fashioned newspapers took steps to provide their readers with news as well as with leading articles, current and literary topics, society gossip, dramatic criticism and law reports. Nothing perhaps was so striking after 1890 as the demand of the French public for foreign and colonial news, or the readiness of the papers to supply it by means of special representatives independent of the news agencies.

In home matters the French press made greater progress still in the rapid and accurate collection of news, and in this respect the provincial press showed more enterprise and more ability than that of Paris. All the best provincial papers had Paris staffs reporting parliamentary proceedings and law cases. Being perfectly independent of purely Parisian opinion or even bias, the decentralization of the French provincial press became complete; it became also more independent politically than the Paris press. Several journals had national reputations: *La Dépêche* of Toulouse, with its 12 editions daily, *Le Progrès* of Lyons, *Le Petit Marseillais* and *La Petite Gironde* of Bordeaux.

3. The 20th Century.—During World War I French newspapers were under severe censorship. Many disappeared for a time because of shortage of paper or manpower. Changes in the French press as a whole were temporary, and prosperity returned after the war.

In 1930 Paris had 23 morning dailies of general circulation, and ten afternoons, while there were 140 dailies in the provinces. Circulation of *Le Petit Parisien* (1876) reached 1,000,000 in 1904; stimulated by its use of U.S. news methods, it distributed 1,700,000 copies daily by 1930. Next was *Le Journal* (1892) with 1,200,000, and third was *Le Matin*, just at the 1,000,000 mark. Characteristic of the popular press were two serial stories, or *feuilletons*, in each issue; front-page opinion articles, signed by well-known contributing editors; and modest sizes of four to ten pages. The better-known political papers were *Le Temps* (1861), the venerable *Journal des débats*, *La Liberté* (1864), *L'Oeuvre* (1893) and *L'Humanité*, founded in 1904 by Jean Jaurès as the Socialist organ but which became Communist in 1920. The main feature of the French press, especially after the Popular Front government (Blum cabinet) came into power in 1936, was its highly political character, newspapers tending to adopt extremes of a polemical nature, while every phase of politics was represented. A number of papers at this time, as before World War I, accepted financial support from foreign embassies and legations. *Le Temps*, however, achieved a peculiar equilibrium because, since it accepted financial help from the Quai d'Orsay, its editorial comment on foreign policy always supported the foreign minister, while its foreign correspondents were financed by foreign sources. It was clear that when Germany overwhelmed France in June 1940 the press bore no small part of the responsibility for the debacle that ensued.

The 25 Paris dailies of general circulation were reduced during the German occupation to half a dozen: *Le Matin*, *L'Oeuvre*, *Le Petit Parisien*, *Le Temps* (renamed *Les Nouveaux Temps* by the Germans), the *Paris-Midi* and *Le Cri du peuple*. They were not all published during the entire period of the occupation and were supplemented by several short-lived newcomers.

Meantime, an irregular underground press opposing both the Germans and their collaborationists grew up. Among leading underground papers were *Franc-Tireur*, *Combat*, *Résistance*, *Libération* and *Défense de la France*. Editorial and mechanical staffs were sometimes caught and executed; *Résistance* ended after about a year because its staff was shot by the Germans.

When France was liberated in 1944, the only prearmistice papers allowed to resume were four which had refused collaboration—*L'Humanité*, *Le Populaire* (Socialist), *Le Figaro* and *L'Aube* (Christian Democratic). The various resistance groups which had published outlaw papers during the occupation now had dailies to represent them in the Paris press, and all those named in the preceding paragraph became competitors for popular favour. Despite the paper shortage that limited each paper to two pages and kept circulations down to prescribed quotas, there was a great demand among French readers, resulting in a boom in the newspaper business and the establishment of more than a score of new dailies in Paris during the first year following the liberation. In July 1946

the size of the Paris papers increased to four pages. But two years later circulations had dropped, advertising had fallen off and costs had advanced alarmingly.

In the early 1960s there were in France 123 general daily papers while Paris had 13, as against 34 after the liberation; their total circulation was 11,500,000 copies of which 4,200,000 were in Paris. *France-soir* had the highest circulation (1,321,000) and used U.S. techniques in headlines, objective news, accent on crime and fresh feature material. It was closely followed from the point of view of circulation by *Le Parisien libéré* (900,000), *Le Figaro* (510,000) and *L'Aurore* (480,000). Although its circulation was around 225,000 copies, *Le Monde* enjoyed from 1945 a considerable reputation, as much in France as overseas for its news and reporting, but it was also criticized for favouring neutrality.

The provincial press after the war rose to heights it had never experienced before. The number of weeklies and periodicals (about 5,000 at the middle of the century) increased by the early 1960s to 15,000. Prominent among these was *Paris-Match* (1,500,-000) and *Jours de France* (515,000). None of the women's magazines exceeds a circulation of 2,000,000 copies.

The Havas News agency, founded by Charles Havas in 1835, achieved a virtual monopoly of foreign news by furnishing the most economical method for newspapers to obtain such news and by cultivating close relations with government. Auguste Havas, Charles's son, took over the Agence Havas in 1850 and six years later added an advertising agency, exchanging his news for advertising space. The agency gained in power during the ensuing 50 years, and in the 1920s absorbed several others. For the 75 years preceding World War II, Havas handled a very large proportion of French advertising, including *publicité d'influence* for government and finance. It handled large sums for the French government and also for certain foreign powers. In 1940 the Vichy government, having taken over the entire Havas business, divided the news and advertising services. The former was called Office Français d'Information; the latter, under the old name, became solely an advertising agency and continued after the liberation.

During the German occupation (1940–44) the Free French set up the Agence Française Indépendante, with headquarters in London, supported by Allied funds. After the liberation this became Agence France-Presse. In the early 1960s it distributed 70,000 words a day to 5,500 subscribers in 106 countries.

English-language journalism in Paris began with Sampson Perry's *Argus* (1809), a Napoleonic organ. This was followed by *Galignani's Messenger* (1814–1904). In 1887 James Gordon Bennett, Jr., founded in Paris the European edition of his *New York Herald*, which became the leading English-language paper on the continent. The *Herald* absorbed the European edition of the *Chicago Tribune* (1917–35) and in 1935 changed its name to *Herald Tribune* to conform with the title of the parent paper. In 1966 a leading Washington, D.C., daily bought into the enterprise, and the paper was renamed the *New York Herald Tribune-Washington Post International*. Demise of the New York paper (*see* above) in April 1967 was followed in May by merger of the Paris edition with the *New York Times*'s international edition (founded 1949; published in Paris from 1960) under the traditional name *Herald Tribune*.

V. OTHER WESTERN EUROPEAN COUNTRIES

1. Norway.—The Norwegian press apparently began with the founding of the *Norske Intelligenz Sedler* in Oslo in 1763, and two years later the *Efterretninger fra Addressecontoiret* in Bergen. The latter was a mercantile and labour bulletin which preceded the partisan political press that eventually came to be characteristic of Norway. Shortly after the union with Sweden in 1814, a number of political papers were begun in Oslo, of which the *Morgenbladet*, still published in the second half of the 20th century as a Conservative daily, became one of the best known. In the early 1960s there were 81 daily papers with a total sale of 1,691,000 copies. The *Aftenposten* of Oslo had the largest circulation—about 173,000 copies.

2. Sweden.—Though a newssheet called *Hermes gothicus* is known to have been published as early as 1624 in Strängnäs, and similar corantos were published in other Swedish towns, the first paper published with regularity appears to have been the *Ordinari post tijdender*, begun in 1645 and, in the second half of the 20th century, the oldest continuously published newspaper in the world, though little more than an official bulletin, under the title *Post och inrikes tidningar*. Its founder was Johan Beijer, Sweden's second postmaster general. It became a daily in 1820. The Swedish press has also the oldest legally protected guarantees of press freedom in the world in the press law of 1766.

The oldest continuously published newspaper in the early 1960s was the *Norrköpings Tidningar Östergötlands Dagblad* founded in 1758. In the early 1960s there were 186 daily papers with a total circulation of 3,809,300. This represented a sale of over 50 copies for every 100 inhabitants, one of the largest ratios in the world. Stockholm papers with large circulations were the liberal *Expressen* (384,000), an evening paper, followed by the liberal *Dagens Nyheter* (350,000) founded in 1864 and the Social Democratic *Stockholms-Tidningen* (144,300), with its evening associate *Aftonbladet* (197,000) founded in 1830, while the liberal *Götheborg-Posten* founded in 1813 had a circulation of 237,100. The conservative *Svenska Dagbladet* (published in Stockholm had a high reputation in and out of Sweden.

3. Denmark.—The first licence to publish a newspaper in Denmark was granted in 1634, and the oldest surviving newspaper is the *Berlingske Tidende*, which began publication, although under a different name, in 1749. Three newspapers have been published under their present name since the 18th century, *Aalborg Stiftstidende*, Aalborg (1767), *Fyens Stiftstidende*, Odense (1772) and *Aarhus Stiftstidende*, Aarhus (1794). They are all conservative newspapers with a circulation of 40,000–60,000.

The main liberal and social-democratic newspapers were founded in the later part of the 19th century. In the early 1960s the most recent addition to the Danish newspapers, the independent *Information*, grew out of clandestine papers of the resistance movement during World War II. Danish newspapers serve a geographical area and the close relations between newspapers and readership is an important characteristic of the Danish press. Morning papers are published seven days a week, usually with a much larger Sunday circulation. The number of dailies declined after World War II but there were 82 published (not counting a similar number of branch papers) in the early 1960s with certified net circulation (seven days a week) of approximately 1,650,000 copies, corresponding to 1.1 per household. Sixty smaller papers have ceased publication since World War II. Ten dailies are published in Copenhagen, selling together about 700,000 copies.

The leading conservative papers in the early 1960s were *Berlingske Tidende* (171,600), Copenhagen, and *Jyllands-Posten* (62,000), Aarhus, with the radical liberal *Politiken* (138,000), Copenhagen. The Social Democratic press published 11 newspapers with a joint circulation of 121,000 copies, the main one being *Aktuelt* (41,000) in Copenhagen. The leading liberal newspapers were *Vestkysten* (44,000), Esbjerg, and *Fyns Tidende* (36,-000), Odense. *Borsen*, Copenhagen, specialized in financial and commercial news. Popular mid-day papers were *B.T.* (162,000), and *Ekstrabladet* (82,000). The news agency Ritzaus bureau, created in 1866, is owned jointly by the Danish press.

4. Iceland.—Iceland had a monthly periodical as early as 1773. A weekly, *Thjodólfur*, was begun in 1848; and the first daily was *Dagskrá* (1896). The oldest surviving daily paper in the early 1960s was the Conservative *Visir* (1910), and the daily with the largest circulation was another Conservative paper, *Morgunbladid*, followed closely by the Progressive or Co-operative party's *Timinn*. The Social Democratic *Althýdubladid* and the Radical-to-Communist left *Thjódviljinn* were also dailies of importance.

5. Finland.—The first newspaper in Finland was published in the Swedish language in 1771, and the first in Finnish appeared in 1776. The oldest paper still published in the early 1960s was the *Åbo Underrättelser* (1824) of Turku, while the oldest in Helsinki, the capital, was *Uusi Suomi* (1847). Largest of the dailies was the *Helsingin Sanomat* (1889), with 270,000 circulation. There were 93 daily papers in the early 1960s of which 11% were printed in Swedish, the most important being *Hufvudstadsbladet*.

6. **Belgium.**—Some of the earliest newssheets in Europe were printed in Belgium. It has been claimed that Abraham Verhoeven's newssheets, authorized for publication as *Nieuwe Tydingen* in Antwerp in 1605, constitute the first occidental newspaper, though the earliest extant copy is one for 1621. Newspapers were, of course, under the control of the various national authorities which ruled what is now Belgium over the long period before the constitution of 1831 declared for freedom of the press. Under the liberal provisions of that document Belgium developed vigorous newspapers despite the competition afforded by the French press and the hardships suffered in two world wars.

In 1831 the 10 dailies in the country were all printed in French, and as late as 1848 there were 38 dailies, all in that language, but by 1860 there were 9 Flemish dailies. Most of the large Belgian papers had Sunday editions, and some published weekly illustrated supplements.

By the early 1960s there were 47 daily papers in Belgium, some of these being subsidiary or regional editions. Twenty-eight of these were in French, 18 in Flemish and 1 in German, though the combined circulation of the French papers was only slightly higher than that of the Flemish. The combined national circulation of dailies was roughly 2,500,000, of which half was edited in Brussels. Largest of the Brussels papers was *Le Soir* (1887) with 295,000, followed by *Het Laatste Nieuws* (1886) with 270,000, and *La Dernière Heure* (1906) and *La Libre Belgique* both at 170,000. The latter paper was founded in 1885 as *Le Patriote*, but took its present name when it went underground during the German occupation in World War I. The largest Antwerp paper was the *Gazet van Antwerpen* (1891) with a circulation of 167,000; in Ghent the *Het Volk* has a circulation of 210,000, and in Liege *La Meuse* one of 190,000. The national news agency was Belga.

7. **The Netherlands.**—Dutch printers were among the first Europeans to exercise the art, and such early printers as George Veseler, Broer Jonson and Adrian Clarke issued some of the corantos which were the forerunners of regularly published newspapers. Some such papers appeared in Amsterdam before 1620. In 1656 was founded what by mid-20th century was the oldest paper published in the Netherlands, the *Oprechte Haarlemsche Courant*, which became a daily in 1847.

The *Algemeen Handelsblad*, founded in 1828 as *Nieuwe Amsterdamse Courant*, was the first daily in the country. The paper with the largest circulation in 1964 was the Socialist *Het Vrije Volk* (308,700) with editions in 45 cities and towns. Next largest was *De Telegraaf* (281,000), founded in 1893 by H. M. C. Holdert. It was suspended after World War II for its collaborationist activities, but was allowed to resume in 1949. Other widely read papers were the Catholic *De Volkskrant* (162,000); the independent *Het Parool* (215,000); the independent *Algemeen Dagblad* (137,750), Rotterdam; the Catholic *Tijd de Maasbode* (92,500); and the antirevolutionary *Trouw* (100,000), Amsterdam.

The most famous paper outside Amsterdam was the *Nieuwe Rotterdamse Courant* (1843), Rotterdam, founded and conducted by the Nijgh family (circulation 56,000). In 1964 there were 93 newspapers including 10 national dailies. The circulation of the 83 regional dailies was 2,000,000 and that of the national dailies 1,400,000.

The news agency Algemeen Nederlandsch Persbureau was founded in 1934.

8. **Switzerland.**—Newssheets known as *Ordinari Wochenzeitung*, published at Basel in 1610, have been cited as constituting a newspaper and thus the beginning of the history of the Swiss press. Political and religious struggles, however, allowed little opportunity for the development of a regular journalism until the "period of regeneration," which began about 1830 and was followed by the federation of 1848. The federal constitution provided for liberty of the press which, except for short periods during World Wars I and II, was free of administrative control.

Of the 117 daily papers in the early 1960s, 84 were printed in German, 27 in French and 6 in Italian; there was no longer a daily in Romansh. The largest circulation was that of the *Tages-Anzeiger* (1893) in Zürich, with 158,000 daily circulation; all other papers had less than 100,000. However, some of them are well known outside Switzerland, including the *Neue Zürcher Zeitung* in Zürich (1780), the *Gazette de Lausanne* (1798) and the *Journal de Genève* (1826).

9. **Austria.**—At least three weekly newssheets are known to have existed in Vienna before 1620. Though limited in its development by the usual censorships of the 17th and 18th centuries, the Viennese press gained a wide reputation for good writing and criticism. The reign of Joseph II (1780–90) brought a helpful liberality in newspaper licensing, but the following reign and the rule of Metternich were less favourable. The revolutionary disturbances of 1848 brought a new severity into censorship and reduced the 200 papers then published in Austria-Hungary (90 of them dailies) by about half. Not until 1867 was there a relatively free press. Two newspapers which had been founded in Vienna within the first three years of the 18th century—*Posttägliche Mercurii Zeitung* and *Wiener Diarium*—were in 1780 combined as the *Wiener Zeitung*, long the government organ and serving in that capacity in the early 1960s.

Nearly all the existing Austrian papers had been founded since World War II. The chief exception besides the *Wiener Zeitung* was the *Arbeiter Zeitung* (1889), official Socialist organ, which with the *Österreichische Neue Tageszeitung* (1947), chief organ of the majority People's party, led the Vienna press. *Das Kleine Volksblatt* (1929), a tabloid, also represented the People's party. One of the leading Austrian papers in the early 1960s was the independent daily *Die Presse* while the *Neuer Kurier* had the largest circulation: 226,000 during the week and 296,000 on Saturdays. The provincial press increased in number and influence in the postwar period, partly because of the development of the party press; prominent among these were the *Salzburger Nachrichten* and the *Oberösterreichische Nachrichten* of Linz. Many papers were owned by political groups. In the early 1960s there were 35 dailies with a total circulation of 1,200,000.

10. **Spain.**—The history of the Spanish press is chiefly a history of censorship, with intermittent eras of relative freedom. The first authorized papers appeared only after the declaration for liberty of printing by the *Cortes* of Cadiz on Nov. 10, 1810; this was withdrawn in 1814, re-established in 1820 and then annulled 1823–34. The periods of authorized publication were too short to permit the development of important newspapers. Exceptions to the short-lived nature of newspapers before the constitution of 1869 were the government bulletin *La Gaceta de Madrid* (1661), begun as a monthly, later published weekly and made a daily in 1890; and *Diario de Barcelona* (1792), which, as the leading and semiofficial paper of Catalonia, was independent of Spanish censorship. Spanish papers were generally political, often in revolt against censorship and inadequately financed.

The civil war of 1936–39 reduced daily papers in Spain from 250 to fewer than 100. In the early 1960s there were 105 dailies with a total of around 3,000,000 copies. Control of the press in the second half of the 20th century was somewhat less strict than during the war, though the old system of the *editores responsables* approved by government, first set up in 1833 at the outbreak of the Carlist uprisings, was again in use. In 1962 newspaper censorship was officially alleviated but articles still had to be submitted to the censors and the real extent of freedom of the press was problematic.

Eight daily papers were published in the early 1960s in Madrid. The leading morning papers were *A.B.C.* (Conservative) and *Ya* (Catholic), each printing 175,000 copies, followed by *Arriba*, the political organ of the National movement, with 50,000 copies. Madrid evening papers consisted of *El Alcazar* (colour-engraved), the very popular *Madrid* and *Informaciones* and *Pueblo*, the organ of Syndicates and the largest, with a circulation of 100,000. Six daily papers were published in Barcelona; *La Vanguardia Española* had the largest circulation in Spain (180,000). Nearly all the Madrid and Barcelona morning dailies ran popular Sunday colour-engraved supplements, with a combined total of 200,000 copies.

Growing daily papers in provincial cities were *La Gaceta del Norte* (Bilbao), *El Heraldo de Aragon* (Saragossa), *Las Provincias* (Valencia) and *Ideal* (Granada).

Among weeklies *Siete Fechas* (250,000) was the most popular while *Gaceta Illustrada* had a high reputation.

There were four main national news agencies in the early 1960s, Cifra, Logos, Pyresa and Mencheta, while Efe supplied international coverage.

11. Portugal.—Successive governments of Portugal allowed scant and temporary liberty of the press. The constitutional provisions of 1911, separating church and state, provided for press freedom, but the dictatorship which developed under the constitution of 1933 was unfriendly to independence of the press. Thus no great newspapers have developed in this country.

In 1962 there were ten dailies in Lisbon, four in Oporto, three in Evora, two in Braga and one in Coimbra and Beja. About 150 weeklies, semiweeklies and triweeklies were published in the country. Largest of the Portuguese papers were *Diário de Notícias* (1864) with 120,000 circulation and *O Século* (1880), Lisbon, with 90,000.

12. Italy.—The name "gazette," which was for so long a more common generic designation of printed sheets or pamphlets of news than "newspaper," is believed to have been derived from *gazzetta*, a small coin used in Venice in the 16th century, which may have been the price of early *fogli d'avvisi* or the admission to a group which listened to the reading of such newssheets. Venice was a chief centre for the written newsletters of the middle ages, and weekly printed newssheets appeared in Florence as early as 1636, the work of Amador Massi and Lorenz Landi. The first Italian paper with a continuous title appears to have been *Sincero*, published in Genoa in 1645.

The press of Italy, always subject to more or less severe government controls, lent itself to reform and even revolutionary movements. Giuseppe Mazzini was an active journalist; and Count Cavour's *Il Risorgimento*, which he founded with Count Cesare Balbo in 1847, was the great organ of the national movement. The constitution of 1848 declared for freedom of the press, yet "special laws," it stated, would "punish abuses." Accordingly, a set of press edicts was issued which retained effective political controls and remained in use until the sterner censorship of the Fascist regime.

In 1920 there were 157 daily papers and 843 weeklies in Italy. Following Benito Mussolini's march on Rome in 1922, the national press regulations were adapted to the pattern of a totalitarian state, with very definite editorial policies prescribed for them almost day by day. Opposition papers were suppressed and their editors disposed of. Mussolini himself had been a journalist, editing the Socialist *Avanti* of Milan in 1912–14, and resigning that position to found his own *Il Popolo d'Italia*, which he edited until 1922. Under his dictatorship, Italian dailies were reduced to 50 or 60. Much the oldest of the survivors was the *Gazzetta di Venezia* (1787). *L'Osservatore romano* was founded as the papal organ in Rome in 1861.

The Agenzia Stefani was set up by Count Cavour in 1853 under the management of Wilhelm Stefani. It functioned as a government news agency in Rome under all changes and through the Fascist era. In 1945 a new national news agency was created under the name Agenzia Nazionale Stampa Associata (ANSA).

World War II put an end to many of the older newspapers but with peace came many new ventures, and in the early 1960s there were 95 daily newspapers published, 27 of which were evening papers and 4 sports papers; 3, including the *Daily American* in Rome and the German *Dolomiten* at Bolzano, were published in foreign languages. Of the daily papers 54 were published in northern Italy (12 in Milan) and only 7 in southern Italy (5 in Naples). Twenty dailies were published in Rome and nine in the islands. There were 102 periodicals with circulations of over 25,000.

The *Corriere della sera* (Evening Courier; 1876) of Milan had the largest circulation, 496,000; despite its name it was a morning paper with an evening associate *Corriere d'informazione*. *Il Giorno* (1955), owned by the Ente Nazionale Idrocarburi, was also published in Milan (330,000). *La Stampa* (372,000) was founded in Turin as *La Nuova Stampa* (1868). In Rome leading dailies were *Il Messaggero*, *Il Tempo*, the Communist party paper *L'Unità* (1945) and the Socialist party paper *L'Avanti*. The Rizzoli publishing house planned to open the first national daily *Oggi* in 1964, printing simultaneously in Milan and Rome.

A particular feature of Italian journalism was the *terza pagina* ("third page"), traditionally devoted to culture, book or theatre reviews and scientific discoveries.

13. Greece.—The first Greek papers were published in foreign capitals by refugees from Turkish rule and propagandists for Greek freedom. These appeared in Vienna, Paris and London from 1790 to 1820. The first Greek paper in the homeland appeared immediately after the beginning of the Greek war for independence—the *Salpinx Helleniki*, founded at Nauplia in 1821. An especially interesting journal was the *Hellenika Chronika*, edited 1824–26 at Missolonghi by a Swiss doctor, Jacques Mayer.

In the mid-1960s there were 95 daily papers published, of which 27 appeared in Athens. The largest of these was *Ta Nea* (118,000) and the second largest and oldest in the country was *Akropolis* (80,000) founded in 1881. The daily *Kathimerini* (1919) had a sale of about 40,000. The largest papers outside Athens were *Makedonia* (1908) with a sale of about 31,000 and *Ellinikos Vorras* with one of 22,000, both published in Salonika.

14. Turkey.—The earliest papers in Turkey were French journals published in the last decade of the 18th century. The first Turkish paper was *Takvime Vekayi* ("Calendar of Events"), a version of *Moniteur Ottoman*, begun in the same year (1831) by Alexandre Blaque. A period of severe repression followed the first press law in 1865 though the constitution of 1908 released a flood of new Turkish newspapers. The establishment of the republic in 1923 and the change from the Arabic to the Latin alphabet in 1928 enabled considerable development of the press. Press freedom was guaranteed by the 1961 constitution.

In the mid-1960s there were 836 daily publications and 817 periodicals being published. Of the newspapers and periodicals, 93 were published in foreign languages: 40 in English, 11 in Armenian, 15 in Greek, 11 in French, 5 in German and 4 in Italian. Total newspaper circulation was around 1,353,000, leading dailies being *Hürriyet* (about 500,000) and *Milliyet* (300,000), both published in Istanbul, the Turkish press centre. Of the leading dailies distributed all over the country, 13 of them were published in Istanbul and 8 in Ankara. These are mostly politically independent, although a few have party affiliations, such as *Ulus* (Republican People's party), in Ankara.

VI. EASTERN EUROPEAN COUNTRIES

1. The U.S.S.R.—The first Russian journal is said to have appeared in 1703, but the severe censorship imposed upon the press by the government prevented the development of a press adequate to the extent and population of the country. As newspapers developed in the 19th century, they came to emphasize literature and art and the political policies of government. Nicholas I permitted only 6 newspapers to be published at mid-19th century, but Alexander II allowed more than 60 to be started in the first decade of his reign, 1855–65. These papers soon developed a radical individualism (known as nihilism) which brought back strong repressive measures against the press, and these remained in effect past the end of the century. By 1913 there were 859 papers in all of Russia, approximately 50 of them dailies. A quarter of the daily papers were published in St. Petersburg. Among the latter were such famous papers as *Novoye Vremya* and *Ryech*.

Meantime, the revolutionary press, now regarded as the forerunner of the modern Soviet Union press, began with *Kolokol* ("Bell"), founded first as a monthly by the refugee A. I. Herzen in London in 1857; it was soon made a fortnightly and lived for ten years, exerting a considerable influence on reforms in Russia. Similar revolutionary journals were set up by refugees in other capitals, such as Geneva and New York, and in the 1880s and 1890s there were many illegal sheets in St. Petersburg. The first legal bolshevist paper was *Novaya Zhizn* ("New Life"), founded under Lenin's leadership in 1905. In 1910 *Zvezda* ("Star") was founded in St. Petersburg to combat other leftist groups, and two years later its place was taken by *Pravda* ("Truth"), which after the Revolution of 1917 became the leading Soviet organ and was published at Moscow.

In 1922 the periodical publications of the U.S.S.R. were placed in a carefully devised system which was enlarged to great proportions. Propaganda for the economic, political and social building and maintenance of the U.S.S.R. became the dominant function of the Soviet press.

Various central (All-Union) papers are published in Moscow including the party paper, *Pravda*, and that of the Soviets, *Isvestiya* (1917), those catering for special interests such as agriculture, business and culture as well as those of the social organizations such as the young communists, the trades unions, the union of writers and the sports organizations. At the republican level the papers tend to be joint publications of the party, state and government.

In the early 1960s there were 6,804 news publications in the U.S.S.R. with an aggregate print of 66,700,000. Twenty-five of these, with a total print of 23,524,000, were national newspapers, 180 were republican papers, 96 were regional papers and roughly 3,800 were local city papers. The rest were small, institutional papers, published at army installations, in schools and scientific institutions, and in factories and mills. In addition to these newspapers there were 2,740 collective farm newspapers printed in 17 languages, with a total print per issue of 1,900,000 copies. Newssheets pasted on walls were a regular feature of Soviet life in almost every factory, office, farm, school, college and army unit and some produce several, covering sports, arts and culture, etc. Many institutions also issued a regular mimeographed newssheet

Newspapers in the Soviet Union in the early 1960s were published in 60 languages, one-third of which did not exist as written languages before the Revolution. Of these newspapers 4,665 were in Russian; the other main groups were Belorussian, 154 papers; Uzbek, 112 papers; Ukrainian, 814 papers; Kazakh, 144 papers; and Georgian, 95 papers. Seven foreign language papers were also published.

Pravda was the leading party paper of the Soviet Union; it appeared every day of the year and tended to publish official statements in full. During World War II it was reduced to 2,000,000 but in the early 1960s it had one of the world's largest circulations, publishing 6,700,000 copies. Mats were sent by air to different parts of the U.S.S.R. where regional editions were printed. Leading party papers outside Moscow in the early 1960s included *Leningradskaya Pravda* (Leningrad), *Radyanska Ukraina* (Kiev), *Zvyazda* (Minsk), *Moldova Socialiste* (Kishinev), *Kommunist* (Tiflis), *Sovietakan Hayastan* (Yerevan), *Sotsialistik Kazakhstan* (Alma-Ata), *Kzyl Uzbekistan* (Tashkent), *Sovettik Kyrgyztan* (Frunze) and *Tajikistani* (Dushanbe).

Among leading Moscow papers was *Izvestia*, which had in the past tended to be an official gazette. In 1960 it was converted from a morning to an evening paper and its circulation in the early 1960s was 4,150,000. It published a Sunday supplement *Nedelya* (The Week). *Krasnaya Zvezda* was the daily organ of the armed forces. *Trud* (1,540,000) was published daily by the central council of trades unions and *Gudok* by the railways. Other papers were the building *Stroitelskaya gazeta* (thrice weekly), the agricultural *Selskaya Zhizn* (daily) and the business paper *Ekonomicheskaya gazeta*. *Sovetskaya Rossiya* (the Communist party and Russian Soviet Federated Socialist Republic government) printed 1,955,000 copies and *Sovetsky Sport* 850,000.

The central youth daily, *Komsomolskaya Pravda*, circulated 3,350,000 copies; *Pionerskaya Pravda*, published twice weekly for children, 4,050,000 copies.

Cultural papers published in Moscow were *Literaturnaya gazeta* thrice weekly and circulating 620,000 copies, *Sovetskaya Kultura* issued twice weekly by the ministry of culture and *Literaturnaya Rossiya* (weekly) started in 1963.

The official news agency Telegrafnoye Agentstvo Sovietskogo Soyuza (Tass) was founded in 1925 to collect foreign as well as domestic news for distribution to Soviet papers and after 1961 there was an unofficial agency *Novosti* which distributed news, feature articles and interviews, etc., to the foreign press as well as to the Soviet press.

2. The Baltic S.S.R.—There were Estonian newssheets as early as the 17th century, but the modern press of Estonia began with the foundation of the *Postimees* in 1857, which in 1939 had a circulation of 25,000. The *Päewaleht* (1905) and *Uus Eesti* (1934) had the largest circulations, each of about 50,000. In 1939 the country had 15 dailies, 12 of them in Estonian. The leading Communist dailies after 1945 were *Rahva Hääl* in Estonian and *Sovietskaya Estonia* in Russian.

The earliest Latvian newspaper was the daily *Latviešu Avīzes*, founded at Jelgava (Mitau) in 1822. The weekly *Mājas Viesis* was published in 1856, while in 1862 *Pēterburgas Avīzes* was published in St. Petersburg where censorship conditions were easier. *Baltijas Vēstnesis* (1868) and *Balss* (1878) were founded in Riga. The left-wing movement exerted a big influence with *Dienas Lapa* from 1886. The Riga paper *Jaunā Dienas Lapa* (1906) changed its name many times because of censorship. *Jaunākās Ziņas* (1911) was the biggest daily during Latvia's independence (200,-000). In 1939 there were 133 papers, 22 of them dailies. After occupation in 1940 all papers were stopped except *Cīņa*, the Communist party paper formerly printed in Moscow. In the 1960s *Cīņa* appeared 300 times a year and *Padomju Jaunatne* 256.

The first Lithuanian newspaper, the *Kurjer Litewski*, was founded at Vilnius (Wilno) in 1759 and was printed in Polish. The first paper in Lithuanian was *Aušra*, founded in 1883, which in 1889 was replaced by *Varpas*, both being published at Tilsit in what was then East Prussia. In 1905 the daily *Vilniaus Žinios* was founded at Vilnius. The *Lietuvos Aidas*, founded at Vilnius in 1917, was later transferred to Kaunas and in 1939 had a circulation of 17,000. There were more than 100 periodicals in Lithuania before 1940. After 1945 the two leading Communist dailies were *Tiesa* in Lithuanian and *Sovietskaya Litva* in Russian.

3. Poland.—The origins of the Polish press go back to 1661 when Jan Aleksander Gorczyn started to publish his *Merkuriusz Polski*, first in Cracow and later in Warsaw. The first newspaper in Warsaw was the *Gazeta Warszawska*, which started in 1774. The *Kurjer Warszawski* was founded in 1821. Before World War I there were important newspapers in all the three parts of Poland—Russian, German and Austrian—but only in the last named was the press free. After the restoration of Polish independence the press remained regional; with a few exceptions, none of the dailies had a national circulation. In 1937 there were 2,692 periodical publications, including 184 dailies. Among newspapers published in Warsaw the Roman Catholic *Mały Dziennik* had the largest circulation (125,000), followed by the *Kurjer Warszawski* (60,000) and the *Gazeta Polska* (30,000). The *Illustrowany Kuryer Codzienny*, founded in Cracow in 1906, had a circulation of 80,000 in 1937. In Poznan the largest circulation was that of *Kurjer Poznański* (40,000), founded in 1906. The Socialist daily *Robotnik* had a circulation of only 15,000 but it was famous for having been published from 1894 to 1918, clandestinely or abroad. Its first editor was Joseph Pilsudski.

The entire Polish press was closed down by the Germans in 1939. None of the pre-1939 newspapers was allowed by the Russians to reappear after 1945. By 1948 the press was under complete Communist control. From 1956 the Polish press fought for more objective reporting, better information and the supression of censorship. Compared with that of other Communist countries, the Polish press was readable, vivid and independent.

In the early 1960s, 53 daily newspapers were published with a combined circulation of 5,650,000. Ten dailies were published in Warsaw alone, among them *Trybuna Ludu* (300,000), the central organ of the Polish United Workers' party. Ten provincial towns published two or more papers. The most popular evening paper was *Expres Wieczorny* (465,000), published in the capital.

Among the periodicals with large circulations were *Przyjaciółka* (Woman's Friend), 1,850,000, and *Gromada-Rolnik Polski*, a farming paper, 550,000. Popular weeklies included *Przekrój* (Cross Section) and *Swiat* (World), as well as *Polityka* (Politics), a political and social weekly. After 1945 there was only one official news agency, PAP (Polska Agencja Prasowa).

4. Czechoslovakia.—The oldest Czech daily newspaper was the *Národni Listi* founded in Prague in 1860. It was followed by

the *Národní Politika* in 1883, by the *Lidové Noviny* (Brno) in 1893, the Social Democratic *Právo Lidu* in 1897, the *České Slovo* in 1909 and the Agrarian *Venkov* in 1917. After the creation of the republic the Communist *Rudé Právo* appeared in 1920. In 1937 the total number of periodical publications was about 3,500, including 1,200 in Prague alone. The largest circulations in 1937 were those of *Polední List* (120,000), *Národní Politika* (145,000) and *Právo Lidu* (118,000). In Slovakia the largest newspapers were the *Slovák* (45,000) and the *Slovenský Dennik* (40,000), both in Bratislava. There were also German, Magyar, Polish and Ukrainian newspapers. The *Deutsche Zeitung Bohemia*, founded in Prague in 1828, was the oldest daily newspaper published on Czech territory.

The Czechoslovak press was of high standard, both technically and in the manner of news reporting. It disappeared with the annexation by Germany in 1939. After 1945, of the pre-World War II newspapers, only *Rudé Právo* continued to appear, becoming the organ of the Communist party and having in the early 1960s a circulation of 1,000,000. There were, in the early 1960s, 19 dailies in Czechoslovakia of which 8 were published in Prague and 5 in Bratislava. Other dailies were: *Lidová Demokracie* (organ of the People's party), *Práce* (trade unions) and *Mladá Fronta* (Youth league). There was only one official news agency, ČTK (Československá tisková kancelář).

5. Hungary.—A Latin weekly sheet, *Nova Posoniensia*, founded in Pozsony (now Bratislava, Slovakia) by Matyas Bel in 1721, was the first Hungarian journal. The first periodical in Magyar was the weekly *Magyar Kurir*, founded by Samuel Decsy in Vienna in 1789. The first Magyar journal, circulated privately in Budapest under the title *Országyülési Tudositások*, consisted of the parliamentary reports of Lajos Kossuth (1832–36). In 1841 Kossuth became editor of the Liberal daily *Pesti Hirlap*, while Counts Aurel and Emil Dessewffy started the Conservative *Világ*. There was a remarkable development of the Hungarian press after 1867, with great latitude for free expression. The number of periodical publications increased from 80 in that year to about 2,000 in 1914. After World War I the Hungarian press was reduced in numbers; in 1937 it comprised about 1,200 publications, including 74 dailies. The *Függetlenség*, a daily newspaper founded in 1933 by Gyula Gombos, had the largest circulation (160,000). It was followed by the *Pesti Hirlap* (100,000), the Social Democratic *Népszava* (founded 1872; circulation 180,000) and *Az Est* (founded 1909; circulation 60,000). After 1945 the Hungarian press recovered much freedom, and by 1964 was not entirely Communist controlled (*e.g.*, *Népszava*, above, and *Magyar Nemzet*, organ of the Patriotic People's front, 120,000). *Szabad Nep*, the principal party organ, changed its name to *Népszabadság* (People's Freedom) after the rising of Oct.–Nov. 1956.

In the early 1960s, 26 dailies were published in Hungary, 4 of these, including *Népszabadság* (700,000), being published in Budapest. Total circulation was 1,635,000 compared with 1,078,000 before World War II. Numerous weeklies and periodicals were also published; *Szabad Föld* (Free Land), *Nök Lapja*, the illustrated weekly of the council of Hungarian women, and *Ludas Matyi*, a satirical paper, all have a wide circulation. Papers were also published for the German, Serbian-Croatian, Slovak and Rumanian population.

6. Rumania.—The first Rumanian political periodical was the *Curierul Românesc*, founded in Bucharest in 1828 by I. Eliade Rădulescu, while the first daily in Rumanian, the *Gazeta Transilvaniei*, appeared in 1838 in Brasov (Kronstadt), then in Hungary. The press developed after the union of the principalities (1859) and more so after the country's unification (1918). By 1937 there were 2,253 periodicals including 104 dailies. *Universul*, founded in 1882, had the largest circulation (140,000); it ceased publication in 1953. Other important newspapers were *Adeverul* (100,000), *Dimineața* (90,000), *România* (80,000) and *Argus* (30,000). The restored freedom of the press after World War II was quickly stifled and by 1948 strict Communist censorship prevailed. In the early 1960s there were 32 daily papers of which 19 were in the languages of national minorities. Their combined print total was 2,850,000. *Scînteia* (880,000) was the main Communist party daily organ, *Rominia Liberă* being the government's organ and *Munca* that of the trade unions.

7. Bulgaria.—The first political newspaper published in Bulgarian, the *Bulgarski Orel*, was founded in 1846 in Leipzig, Ger., by Ivan Bogorov. Two years later the Turkish government authorized the publication in Istanbul of the *Tsarigradski Vestnik*. The first daily published on Bulgarian soil was the *Balkanska Zora* founded in 1890 at Plovdiv. The first daily in Sofia was the *Vecherna Poshta*, founded in 1900. By 1914 there were 310 periodical publications. In 1937 there were 25 dailies in Sofia alone with *Utro* and *Zora* having the largest circulations (85,000 and 73,000 respectively). In the early 1960s there were 292 newspapers and periodicals published, including 70 provincial papers with a combined circulation of 1,700,000 and 8 daily papers in Sofia with a combined circulation of 1,500,000. The leading dailies were *Rabotnichesko Delo* (450,000), organ of the Central Committee of the Bulgarian Communist party, followed by *Otechestven Front* ("Fatherland Front"; 200,000) and the organs of the Youth union *Narodna Mladezh*, of the Agrarian union *Zemedelsko Zname* and of the trade unions *Trud*. Popular weeklies were the satirical journal *Sturshel* ("Hornet") and *Septemuriiche* for children. Papers were also published in several foreign languages.

8. Albania.—The first daily newspaper, the *Ora*, was founded at Tirane in 1930. From 1945 there were two daily newspapers: *Zëri i Popullit* ("The Voice of the People"), the Communist party organ, and *Bashkimi* ("Union"), the organ of the People's front.

9. Yugoslavia.—The first newspaper in Serbian, *Srpskija Novini*, was founded in 1791 in Vienna; later Serbian journals appeared in Budapest and Venice. The first newspaper published in Serbia was *Srbske Novine* (Kragujevac, 1834), the first in Croatia *Narodne Novine* (Zagreb, 1835), the first in Slovenia *Ljubljanske Novize* (Ljubljana, 1797). After the creation of independent Yugoslavia in 1918 the Serbian, Croatian and Slovene press developed considerably in numbers and quality. In 1937 there were 1,231 periodicals including 50 dailies; *i.e.*, 13 Serbian (mainly in Belgrade), 21 Croatian (mainly in Zagreb), 6 Slovene (mainly in Ljubljana) and 10 dailies published by the national minorities. In 1939, among the Serbian newspapers the *Politika* (1904) had a circulation of 100,000, the *Vreme* (1921) 65,000 and the *Pravda* (1904) 38,000; in Croatia the *Novosti* (1906) and in Slovenia the *Slovenec* (1871) had circulations of 30,000 each. The Croatian *Obzor*, the oldest existing Yugoslav daily (founded in 1860), in 1939 had a circulation of 7,000.

After World War II the number of papers increased. The most circulated papers were *Borba* and *Politika* (Belgrade). *Borba* was the organ of the Socialist Alliance of the Working People of Yugoslavia, and *Komunist* (issued weekly) was the official organ of the League of Communists of Yugoslavia. *Borba* was published in two editions, in Cyrillic for Serbia, Montenegro, Macedonia, Bosnia and eastern Hercegovina, and in Latin characters for Croatia, Slovenia, Bosnia and western Hercegovina. Other important papers in the early 1960s were *Vjesnik* (Zagreb), *Delo* published in Slovenian (Ljubljana), *Oslobodjenje* (Sarajevo), *Nova Makedonija* published in Macedonian (Skopje) and *Pobjeda* (Titograd). The official news agency, Tanyug, provided uniformity in all except regional and occupational news.

VII. COMMONWEALTH OF NATIONS

1. Canada.—The first Canadian newspaper was the *Halifax Gazette*, founded by John Bushell as a two-page weekly in 1751. In 1770 Anthony Henry combined this paper with his *Nova Scotia Gazette* and continued it for many years. First paper in Quebec was the *Quebec Gazette*, founded by William Brown and Thomas Gilmore in 1764 and printed in both English and French; it lasted for more than 100 years and was finally merged in the *Morning Chronicle* (1847) which, after a combination in 1926 with the *Telegraph* (1872), became known as the *Chronicle Telegraph*. First in Montreal was *La Gazette Littéraire*, founded in 1778 by Fleury Mesplet (a protégé of Benjamin Franklin) and Charles Berger; the modern *Montreal Gazette* is its descendant. First Ontario paper was Lewis Roy's *Upper Canada Gazette and American Oracle*, established in 1793.

By the early 1960s Canada had over 100 daily newspapers and about 900 weeklies, semiweeklies and triweeklies. Total daily newspaper circulation in Canada was about 4,200,000. Among the leading English-language papers were the *Toronto Daily Star* (1892) with the largest circulation in Canada, the *Toronto Evening Telegram* (1876), the *Toronto Globe and Mail* (1844), the *Vancouver Sun* (1886), the *Montreal Star* (1869), and the *Winnipeg Free Press* (1874). French language dailies included *La Presse* of Montreal (1884) and *Le Soleil* of Quebec (1880).

A feature in the Canadian newspaper industry in the 1960s was the trend towards consolidation of newspaper ownership. In 1963 when control of the *Vancouver Sun* passed into the hands of Free Press Publications Ltd. of Winnipeg, the Bell-Sifton interests controlled about half of the total western daily circulation of just over a million. Other leading newspaper groups were those of the Southam company and the Thomson company. Consolidation did not, however, extend to the largest of the eastern dailies which continued to operate separately.

Of the 112 daily newspapers in Canada, 101, including all the principal papers, are members of the Canadian Press, the leading national news service. The Canadian Press Ltd. was established in 1911 as a holding company for the Canadian rights to the news services of the Associated Press, until then held by the Canadian Pacific railway. In 1917 the four regional co-operative news associations set up in the previous ten years were merged into the national news co-operative association of daily newspapers which became known as the Canadian Press. It has sole rights to distribute in Canada the news reports of both the Associated Press and Reuters. After 1952 the CP news reports were made available in both French and English. Through subsidiary companies CP delivers news to the Canadian Broadcasting corporation and most privately owned radio and television stations.

2. Australia.—Australia's first newspaper was the *Sydney Gazette*, a weekly publication of four pages, which appeared in 1803. It was printed by George Howe, a convict, under the direction of P. G. King, then governor of New South Wales. Its policy was dictated by the government and thus the *Gazette* was the first of what has been called the "convict press." Other publications in this class included the *Derwent Star* (1810), the *Van Diemen's Land Gazette* (1814) and the *Hobart Town Gazette* (1816), all published in Tasmania. These publications, subservient to the requirement of official policy, were disliked by the growing number of free citizens in the penal colonies of New South Wales and Tasmania. The remainder of the century, therefore, saw the emergence of privately owned papers, hampered at first by censorship and repression, struggling for freedom of the press, and eventually reaching positions of great financial importance.

The tradition of family-controlled papers has been a feature of this press. In April 1831 three young men, two of them from the *Sydney Gazette*, combined to publish the *Sydney Herald*. It was later acquired by Charles Kemp and John Fairfax, the latter a member of a Warwickshire family who had been part-proprietor of a paper at Leamington, Eng. In 1853 the paper, which had changed its name to the *Sydney Morning Herald*, became the sole property of the Fairfax family, and it remained a family concern until 1956, when a public company was formed, which also acquired control of the *Sun*, a Sydney evening newspaper.

In Melbourne, Victoria, the *Argus*, established by William Kerr in 1846, was bought in 1848 by Edward Wilson. It remained a family-controlled paper, under the proprietorship of Messrs. Wilson and Mackinnon, until 1936, when ownership passed to a public company. Subsequently a controlling interest was acquired by Daily Mirror Newspapers, Ltd., London. Publication of the *Argus* ceased in 1957. Another Melbourne newspaper, the *Age*, which had been started in 1854, was acquired in 1856 by David and Ebenezer Syme, of Scottish origins. For a very long time it continued to be controlled entirely by the Syme family, later becoming a public company. David Syme came to exercise great political power.

The second quarter of the 20th century saw a decline in the number of papers published, both metropolitan and country, while the economic crises of the 1930s caused the closing of some publications. By the early 1960s, however, circulations had more than trebled since 1928. Sydney and Melbourne together had more than half of the circulation of Australian dailies.

There have never been national daily newspapers in Australia with circulations and influence extending throughout the country. This is due chiefly to the immense distances to be covered in delivery, the political division of Australia into six states and the concentration of population on the coastal perimeter of the continent. In the early 1960s the 15 metropolitan daily newspapers published in the six state capitals and Canberra all enjoyed considerable circulation and influence within their own state borders. The largest of these were two Melbourne papers, the *Sun News-Pictorial* (576,000) and the *Herald* (480,000), followed by the *Sydney Daily Telegraph* (327,000), the *Sydney Morning Herald* (304,000), the *Sun* (269,000) and the *Daily Mirror* (260,000). There are 35 dailies published outside the capital cities, combining coverage of world and national news with extensive local news, while nearly every town with a population over 20,000 has some form of local newspaper though only 33 centres support 2 or more, and all but 5 of these are in New South Wales or Victoria. About 3% are in foreign languages.

Magazines are published in all the capital cities, but only a few of them have national distribution. Largest of these is the Sydney *Australian Women's Weekly* (835,000). The Sydney *Bulletin*, a weekly founded in 1880 by J. F. Archibald and John Haynes, was still circulating in the early 1960s.

None of the main Australian dailies has any affiliation with the political parties. In the 1960s the only directly controlled Labour daily paper was the *Barrier Daily Truth* (Broken Hill), owned by the district Workers' Industrial union.

With the exception of the *Sydney Daily Mirror* all metropolitan and provincial daily newspapers take their basic world news through Australian Associated Press, Ltd. (formed in 1935), which is linked with the Reuters organization. The metropolitan newspaper groups, however, maintain their own staffs of correspondents in London, New York and elsewhere as occasion arises.

3. New Zealand.—Pioneer English and Scottish settlements in New Zealand made haste to establish newspapers, sometimes even before houses were built. The people were highly literate for the times, and weekly journals were begun, not so much to supply news as to give vent to political opinion, intended to exert pressure not only on the New Zealand authorities but on the British parliament as well. Thus the Wakefield expedition got out a paper, the *New Zealand Gazette* (Samuel Revans, editor), in London before it sailed in Sept. 1839, and published the second issue on arrival in April 1840. The paper survived at Wellington under various titles till 1868. In the north of the country, where Gov. H. Hobson arrived in 1840 to annex the country as a British possession, the *New Zealand Advertiser and Bay of Islands Gazette* (G. A. Eagar, editor) began publication on June 20, 1840, as a fierce opponent of the governor and his supporters. It ceased at the end of the same year. In Dec. 1840 the first official publication, the *New Zealand Government Gazette*, was printed at Paihia at the Church Missionary society's printing office. Each new settlement had one or more newspapers, many of which had very short lives. Communications were poor—the quickest way of sending news from Dunedin to Auckland was by ship to Sydney, Austr., and thence by ship to Auckland, a matter of 2,500 mi. The Devonshire settlers at New Plymouth founded the *Taranaki Herald* in 1852 and the *Taranaki News* in 1857. They both continue as dailies, the former being the oldest newspaper in New Zealand; the latter changed its name in 1959 to the *Daily News*.

In the early 1960s Auckland, with the largest urban population, had two daily papers, the morning *New Zealand Herald* (205,000) and the evening *Auckland Star* (135,000), with the largest circulations in New Zealand. The two surviving newspapers in the capital, Wellington, are the *Evening Post*, founded by Henry Blundell in 1865, with a circulation in the early 1960s of 94,500, and the *Dominion*, Wellington's morning daily, founded in 1907 by C. W. Earle, and edited by him until his death in 1950. Its circulation in the early 1960s was in excess of 94,000.

Christchurch journalism began with the *Lyttelton Times* which

was founded on Jan. 16, 1851, exactly one month from the day the Canterbury association settlers landed at the port. It had been planned in London, and Isaac Ingram, an Oxford printer, was the first publisher. The first editor was J. E. FitzGerald, a member of the committee of the Canterbury association, who, for the two years of his editorship, fought a continuing battle for self-government for the colony. The *Lyttelton Times*, under the editorship of Sam Saunders, became the leading Liberal paper of New Zealand, particularly in the days of the Seddon government (1893–1906). It was opposed by the *Christchurch Press*, founded in 1868 as a Conservative organ. In the same year the *Times* established an evening paper, the *Star*. Just before the outbreak of World War I, E. C. Huie began publishing another evening paper, the *Sun*. The depression years of 1930–35 found the four daily newspapers engaged in a bitter circulation war which ended with New Zealand Newspapers, Ltd., owners of the *Times* and *Star*, closing the *Times* and absorbing the *Sun*.

Thus Christchurch was left with two daily newspapers, the morning *Press* with a circulation in the early 1960s of over 64,000 and the *Christchurch Star* of over 65,000.

Like other cities, Dunedin had a number of newspapers in the 1860s, mainly induced by the discovery of gold in Otago. The two survivors are the *Otago Daily Times*, founded in 1861, with a circulation of 40,600 and the *Evening Star*, founded in 1863, with a circulation of 30,000.

None of the newspapers in the four main cities have a national circulation although, especially in the North Island, the two morning newspapers, the *New Zealand Herald* and the *Dominion*, have extensive circulations. There are also nearly 60 triweekly, biweekly or weekly newspapers published throughout the country, concentrating mostly on local news. Prominent national magazines include the *New Zealand Woman's Weekly*, the *Weekly News*, *New Zealand Truth* and the *New Zealand Listener*.

New Zealand has 42 daily newspapers who are all partners in the New Zealand Press association, which supplies them with home and overseas news. The Press association receives most of its overseas news through the Australian Associated Press and like A.A.P. is also a partner in Reuters. (A. P. R.; X.)

4. India.—Though printing from movable type was done in India in the 16th century, and there were written newsletters during the Mogul dynasty in that century, the first newspaper appeared Jan. 29, 1780. This was the *Bengal Gazette or Calcutta General Advertiser*, known as "Hickey's Gazette." James Augustus Hickey's attacks on the government and on private individuals resulted first in barring his paper from the post office and then in his arrest and imprisonment and the seizure of his paper. The second paper was Peter Reed's *Indian Gazette or Calcutta Advertiser*, begun later in 1780 and devoted largely to the business of the East India company; it lasted for more than 50 years. Bombay journalism began with the *Bombay Herald* in 1789; the first in Madras was the *Madras Courier* of 1785.

The first periodical in a vernacular language was the monthly *Digdarshan* of 1818, in Bengali, by J. C. Marshman, a Baptist missionary, which soon became a weekly newspaper with the title *Samachar Darpan* ("Mirror of News"). In 1829 it became bilingual, with local and foreign news in both English and Bengali.

In the early 1820s many vernacular papers appeared in Gujarati and Bengali, papers which were suspended under the John Adams press regulations. Active in this journalism was the religious and social reformer Raja Ram Mohun Roy, founder of the first Persian weekly, *Mirat-ul-Akhbar*, in Calcutta. Roy was later associated with *Banga Doot* ("Bengal Herald"), printed in Bengali, Persian, Hindi and English. Most famous of Bengali papers were *Ananda Bazar Patrika*, founded in 1878, and enjoying by the early 1960s one of the largest circulations among Indian dailies (102,000). This paper and the other leading daily in Bengali, *Jugantar* (founded in 1937), were both published in Calcutta.

The leading English-owned paper in India in the early 1960s was the *Statesman* of Calcutta (with a New Delhi edition), founded by Robert Knight in 1875, which absorbed the *Englishman* (1821) and *Friend of India*. Another English-owned paper, the *Pioneer* of Allahabad, founded in 1865, and famous for the service on its editorial staff of Rudyard Kipling for a few years in the latter 1880s, passed under Indian ownership in the 1930s.

Half-a-dozen leading Indian dailies in the English language were owned by Indians in the early 1960s. The *Hindu*, Madras, began as a mimeographed journal of the literary society, became a regular weekly in 1878 and a daily in 1889. The *Times of India* of Bombay (with a New Delhi edition), founded in 1838 as *Bombay Times*, was long regarded as the chief newspaper in India. The *Tribune of Ambala*, East Punjab, founded in 1881 and made a daily in 1960, became a modern and influential paper. The *Amrita Bazar Patrika*, founded in 1860 in a village near Calcutta, was in 1871 moved to that city and was made a bilingual paper. After the Vernacular Press act of 1878, it was made an English paper and became a leading newspaper in India. The *Free Press Journal* of Bombay was founded in 1930 by S. Sadanand, the outgrowth of a news agency. The *Hindusthan Times*, founded in 1923, was edited for a number of years by Devdas Gandhi, son of Mohandas Karamchand Gandhi. The daily with the largest combined circulation was the *Indian Express* (1953), published simultaneously in Bombay, New Delhi and three other cities.

The daily press in India in the early 1960s consisted of more than 300 papers with an aggregate circulation around 4,500,000: 75 in Hindi, 42 in Urdu, 33 in English, 26 in Malayalam, 24 in Tamil, the rest in other languages. In the matter of circulation, however, the English language dailies were at the top (1,150,000), followed by Hindi (745,000), Malayalam (499,000), Marathi (350,000). Of the nine dailies with a circulation of over 100,000, four were in English (*Indian Express*, *Times of India*, *Statesman*, *Hindu*), two in Tamil (*Thanthi*, *Dinamani*), one in Marathi (*Lokasatta*), one in Hindi (*Navbharat Times*) and one in Bengali.

Nearly 40% of newspapers and periodicals of all kinds were concentrated in Bombay, Calcutta, New Delhi and Madras.

Indian newspapers in 1948 formed their own co-operative news agency under the name of the Press Trust of India Ltd., taking over the 50-year-old Associated Press of India Ltd., which was a Reuters subsidiary. The Indian press at the same time joined those of the United Kingdom, Australia and New Zealand in the general management of Reuters.

5. Pakistan.—Following the birth of the new state in 1947, a number of new journals were established. Pakistan lost some of its papers by their removal to India, but gained its largest daily *Dawn*, which moved from Delhi to Karachi, where it continued to publish editions in several languages. Leading English-language papers were the *Pakistan Times* at Lahore, the *Times of Karachi* and *Morning News* at Dacca in East Pakistan and Karachi. In the early 1960s the country had 90 dailies: 70 in West Pakistan and 20 in East Pakistan. In West Pakistan they were printed mainly in Urdu, the most important being *Imroze* at Lahore and Karachi, but some were in Gujarati or Sindhi. In East Pakistan the language was mainly Bengali, the more important papers being *Azad* and *Ittefaq*, both published at Dacca.

6. Federation of Malaysia.—Singapore in the early 1960s had half-a-dozen daily papers published in English, Chinese and the Indian and Malay languages, circulating in the city and also in Malaya. The *Straits Times* (1845) had a special Malayan edition. The other leading papers were *Nanyang Siang Pau*, *Sin Chew Jit Poh* and *Nanfang Evening Post* (in Chinese).

Newspapers in Malaya were likewise in English, Chinese and the Indian and Malay languages. In the early 1960s the more important dailies were the *Straits Times* and the *Malay Mail* (in English), *Berita Harian* and *Utusan Melayu* (in Malay) and *New Life Daily News* and *China Press* (in Chinese).

In Sarawak in the early 1960s there were seven dailies, including six papers in Chinese and one in the English language.

7. Elsewhere in the East: *Ceylon.*—In the early 1960s there were nine dailies, four in English, three in Sinhalese and two in Tamil, totaling over 350,000 copies. Of these the more important were *Dinamina* and *Lankadipa* (in Sinhalese), the *Ceylon Daily News* (in English) and *Thinakaran* (in Tamil). The Sunday paper, *Silumina* (in Sinhalese), had the highest circulation (156,000).

Aden.—There were in the early 1960s four dailies. The leading paper was *Fatat-ul-Jezirah*.

Hong Kong.—There were in the 1960s nine dailies in Hong Kong. The leading papers were *Wah Kiu Man Po, Wa Kiu Yat Po, Ta Kung Pao* in Chinese, and *Hong Kong Tiger, Standard, China Mail* and *South China Morning Post* in English. (Jo. K. B.)

8. Africa: *Ghana.*—In the early 1960s four dailies were published, all in English. Their combined circulation of 200,000 represented 40 copies per 1,000 inhabitants. Seven nondailies and 15 periodicals were also published. *The Ghanaian Times* (Accra) and the *Evening News* (Accra) were financed by government funds. The largest paper, the *Daily Graphic* (Accra), was owned by the Mirror Newspapers, London, until 1962 when it was turned into a trust. The *Ashanti Pioneer* (Kumasi) ceased to be an opposition paper in Oct. 1962 as a result of official action. Press control was exercised both indirectly through government pressure and directly through the criminal code of 1960, which could require periodicals suspected of "systematic publication of matter calculated to prejudice public order or safety . . . to submit all future issues of the periodical to a specified authority to be passed upon before publication." Special significance was attached to *The Spark*, a weekly theoretical paper, published by the Bureau of African Affairs, launched in 1962.

Nigeria.—In the early 1960s, 14 dailies were published, all in English. Their total circulation of 260,000 represented 8 copies per 1,000 of the population. There were 34 nondailies and 32 periodicals. The *Daily Times* and *Sunday Times*, with the largest circulations (both 120,000), were owned by the Mirror Newspaper group. The federal government published the *Morning Post* and the *Sunday Post* (77,000). The largest indigenous group was Zik newspapers (started by N. Azikiwe) controlling five dailies, including the *West African Pilot* (Lagos), and supporting the National Council of Nigerian Citizens. The *Daily Express* (Lagos) supported the Action group, and the *Daily Mail* (Kano) supported the Northern Peoples congress. Except under emergency regulations there were no press laws and censorship.

Sierra Leone.—There was one daily in the early 1960s, the *Daily Mail* (Freetown) owned by the Mirror Newspapers (London). With a circulation of 15,000 it sold 6 copies per 1,000 inhabitants. There were also six nondailies and ten periodicals. There were no press laws or censorship.

Tanganyika.—In the early 1960s there were three dailies, the *Tanganyika Standard* (11,000), published in English, and *Mwafrika* (13,000) and *Ngurumo* (12,000), published in Swahili. Their combined sales reached 4.4 per 1,000 inhabitants. There were also 16 nondailies and 37 periodicals. Prominent Sunday newspapers were *Mwafrika Na Taifa* (30,000) and *Uhuru* (15,000), in Swahili, and *Sunday News* (10,600) and the *Sunday Nation* (8,000), in English. The governing party, the Tanganyika African National union (TANU), launched its own weekly *The Nationalist* in 1964. There were no press laws or censorship.

Zanzibar and Pemba.—In the early 1960s two dailies were published; with a combined circulation of 400 they sold 1 copy per 1,000 inhabitants. There were eight nondailies.

Uganda.—In the early 1960s three dailies were published, the *Uganda Argus* (13,300), *Uganda Eyogera* (12,000), published in Luganda, and *Taifa Empya*. They sold 6 copies per 1,000 inhabitants. Characteristic of the Ugandan press was the growth of indigenous and privately owned papers in many of the local languages.

Gambia.—There was one daily in the early 1960s with a circulation of 1,500 representing 5 copies per 1,000 inhabitants. There were also three nondailies and two periodicals.

Central Africa.—In the early 1960s, four dailies circulated with total sales of 112,000, representing 6 copies per 1,000 inhabitants. There were 36 nondailies and 40 periodicals. The Argus South African Newspapers, Ltd. controlled five of the largest papers, three dailies and two Sundays: the *Rhodesia Herald, Bulawayo Chronicle, Northern News* (Zambia), *Sunday News* and *Sunday Mail*. The largest group specializing in publications for Africans, Thomson Newspapers Rhodesia (Pvt) Ltd., included *Central African Daily News*, the *African Parade*, the *Popular Post* and Malawi's single daily. The Malawi party of H. Banda published a weekly *Malawi News* while the weekly, the *African Mail* in Lusaka, supported K. Kaunda's United National Independence party. A lively political monthly was the *Central African Examiner*.

Kenya.—In the early 1960s there were six dailies, three in English, one in English and Gujerati, one in Gujerati and one in Swahili. The largest of these were *East African Standard, Daily Nation* and *Taifa Leo* (Swahili), all published in Nairobi. The combined circulation of the six was 88,000 representing 7 copies per 1,000 inhabitants. There were 26 nondailies. East Africa Standard Ltd. owned *East Africa Standard* (weekly edition 42,000) and *Baraza* (39,000) published in Swahili. East African Newspapers Ltd. (with which were associated the Aga Khan and the Thomson Newspaper organization) owned the *Nation* (Sunday edition 31,000) and *Taifa* (weekly 59,000), published in Swahili. There were 40 periodicals, the government information service publishing 10 vernacular papers.

High Commission Territories.—In Basutoland there were four nondailies in the early 1960s with a combined circulation of 25,000 representing 28 copies per 1,000 inhabitants. There was also one periodical. Bechuanaland had one periodical, published by the government. In Swaziland, two nondailies with a joint circulation of 1,900 sold 8 copies per 1,000 inhabitants.

Mauritius.—There were nine dailies in the early 1960s with a circulation of 40,000, representing 68 copies per 1,000 inhabitants. There were also 11 nondailies and 15 periodicals. (Co. L.)

VIII. CENTRAL AND SOUTH AMERICA

1. Mexico.—A Mexican newssheet published in 1541 constituted the earliest printed news in the western hemisphere. It was published by Juan Pablos and was an account of the Guatemalan earthquake of the preceding year, entitled *Relación del terremoto de Guatemala*. The first regular newspaper came nearly two centuries later, *Gaceta de México* (1722). The first dailies were *Diario de México* and *Diario de Veracruz*, both begun in 1805. Arbitrary censorship was the rule and tradition in Mexico. The constitution of 1857 was liberal in language, but did not in practice afford any considerable freedom of the press. In the long presidency of Porfirio Díaz, however, economic stability was favourable to the development of the newspaper industry. The "insurgent press," beginning with *El Despertador Americano* (1810–11), from time to time played an important part in national affairs. Papers in Indian languages were established in the 1880s, as *Purepe* of Quiroga, in Tarascan; *Mor* of Tepoztlán, in Aztec; and others in Maya and Zapotecan in Yucatán and Oaxaca.

Daily newspapers in Mexico in the 1960s numbered more than 140, of which about 20 were published in the federal district. Nearly all had been founded after 1920 and many after 1940. The only important daily dating back to the 1880s was *El Correo de la Tarde* (1885) of Mazatlán. The largest papers in Mexico City were: the established and respected *El Universal* (1916), with its evening tabloid edition, *El Universal Gráfico* (1922); *Excelsior* (1917); *Novedades* (1932); and *La Prensa* (1928). These journals had large Sunday editions and affiliated radio stations. There was one paper owned and operated by the government, *El Nacional* (1929). Guadalajara and Monterrey, the next largest cities, had three and four dailies respectively. The circulation of Mexican dailies, regional rather than national, virtually doubled in the decade 1940–50 and continued to increase thereafter.

2. Central America.—The earliest printing in Central America was at Antigua, in the colony of Guatemala; but it was in the town of Guatemala that a monthly *Gaceta* was established in 1729. Of the dailies being published there in the 1960s, the oldest was *Diario de Centro America*, founded the year after the adoption of the constitution of 1879 as *El Guatemalteco; El Imparcial* (1922) and *Prensa Libre* (1951) had the largest circulations.

In Honduras the first paper was the *Gaceta de Honduras* (1830), in Comayagua; the first daily was *El Diario* (1897), in Tegucigalpa, the capital. In the 1960s Honduras had five dailies.

British Honduras had the *Belize Daily Clarion* (1897) and the *Belize Billboard* (1946).

Nicaragua's first paper was *El Telégrafo Nicaragüense* (1835) of León, and its first daily was the *Diario de Nicaragua* (1884)

of Granada. In the 1960s there were five dailies in Managua and one in León.

El Salvador had a paper at San Sebastian called *Liberal Guipuzcoano* in 1820. Of the dailies being published in the capital, San Salvador, in the 1960s *Diario Oficial* (1847), the government gazette, was the oldest, and *La Prensa Gráfica* (1915) and *El Diario de Hoy* (1936) foremost in circulation and influence. Sonsonate and Santa Ana each had one daily.

El Noticioso Universal, established by Joaquin Bernardo Calvo at San José in 1832, was Costa Rica's first newspaper. There were five Spanish-language dailies in that city in the 1960s, with circulation ranging from 10,000 to 40,000, and also one daily in English.

In what is now Panama, *Misceldnea del Istmo* was established in 1822, and short-lived political papers appeared from time to time; but modern Panamanian journalism began with the founding of the *Panama Star* by a group of American forty-niners bound for California but temporarily detained awaiting ship. Their main purpose appears to have been to publish an account of their celebration of Washington's birthday, and the paper was begun Feb. 24, 1849. The paper soon came into other hands, and when Panama seceded from the Colombian federation in 1853 it was made a daily and given a Spanish section, which eventually became a separate edition called *La Estrella de Panamá*. The *Panama Herald* (1851) was absorbed in 1854, and the English edition became *Panama Star & Herald*. The *Panama American* and its associate *El Panamá-America* began in 1925, and the *Nation* and *La Nación* in 1944.

3. Cuba.—Sporadic publication of printed newssheets goes back to 1707 with the appearance of *Disertación Médica Sobre las Islas de Barlovento*, a medical report on dietary conditions in the Windward Islands. In 1764 the Havana printer Olivos was ordered by the colonial authorities to issue a monthly *Mercurio*, and other official gazettes were published later. But the first general newspaper in the island was the *Papel Periódico de la Habana* (1790), issued under the enlightened administration of Captain General Luis de las Casas. Strict censorship was the rule under the colonial government.

After independence there was a rapid flourishing of the Cuban press, and some of the largest and more modern newspapers in the hemisphere were published in Havana in the late 1950s. Though government censorship or interference was only occasional, unofficial political subsidies accounted for considerable government influence in many newspapers. Before the Fidel Castro revolution there were about 48 dailies in the island, over 20 of them published in Havana. Among them were the *Diario de la Marina* (1832), oldest extant Cuban paper at the time, *El Mundo* (1901), *Información* (1933) and *Diario Nacional*, all of them morning dailies with circulations ranging between 25,000 and 75,000; *El País* (1921) and *Prensa Libre* (1941), both evening papers with circulations over 100,000. Among foreign-language dailies there were two in English, the *Havana Post* (1895) and the *Times of Havana* (1957), and three in Chinese.

After the accession of the Castro regime in 1959 mounting political pressure caused many Cuban newspapers to cease publication, among them some of the oldest and most respected. All others came finally under complete control of the government, exercised in many cases through the labour unions and, in others, by means of a direct government *interventor*. The three most important Cuban dailies being published in the 1960s were *Hoy*, traditionally the organ of the Cuban Communist party; *Revolución*, which in an earlier form had been the clandestine organ of Castro's revolutionary movement against Batista; and *El Mundo*.

4. West Indies.—The *Gazette du Cap*, of uncertain history, is said to have been Haiti's first paper. The *Gazette politique et commerciale d'Haiti* (1804) was the first government organ of the new republic. In the 1960s Haiti had six daily papers, all published at Port-au-Prince; the largest had a circulation of about 9,000. Larger in circulation were the dailies at Santo Domingo in the Dominican Republic, *La Nación* (1940), *El Caribe* (1947) and *El Listín Diario* (1893). The latter had been suppressed during the Trujillo dictatorship.

La Gaceta was founded as the official organ of the Spanish government of Puerto Rico in 1807 and continued until the occupation of the island by United States forces in 1898. In the 1960s there were two Spanish-language dailies in San Juan, *El Imparcial* (1917) and *El Mundo* (1919), which claimed more than 50,000 circulation each, and one English-language daily. There was one daily each in Ponce and Arecibo.

Robert Baldwin began the *Weekly Jamaica Courant* in 1718 at Santiago de la Vega, the capital of Jamaica until 1872. In the 1960s the morning *Daily Gleaner* (1834) was the chief paper of Kingston, and the evening paper was the *Star* (1951).

5. Colombia.—Manuel del Socorro Rodriguez, a Cuban *émigré*, was the publisher of the earliest papers issued in what was then called Santa Fé de Bogotá; they were the *Gaceta* (1785) and the *Papel Periódico* (1791–95). *El Tiempo* of Bogotá, largest paper in the country, suffered under the heavy hand of government censorship in the mid-1950s; in the latter years of the decade and in the 1960s government pressure on the press was markedly reduced. Largest paper outside the capital was *El Colombiano* (1912) of Medellín.

6. Ecuador.—The first known newspaper in Ecuador was the *Gaceta de Santafé* (1785) of Quito. No further paper was printed in the country until after the revolution of 1809, when the *Gaceta de la Corte de Quito* was begun. In the 1960s *El Comercio* (1906) was the most important of Quito's dailies; it also owned *Últimas Noticias* (1938), the capital's only evening paper.

7. Venezuela.—The first Venezuelan newspaper was the *Gaceta de Caracas* (1808). The oldest daily in Venezuela in the 1960s was *La Religión* (1890) of Caracas; those with the largest circulations were *El Mundo* and *El Nacional*, both of Caracas, each over 100,000.

8. Peru.—Probably the earliest newssheet printed in South America described the capture of the pirate Richard Hawkins off the Peruvian coast; it was issued by Antonio Ricardo at Lima in 1594. The first titled and numbered paper was *Gaceta de Lima* (1744). Peruvian newspapers, both under Spanish rule and after establishment of the republic in 1822–23, were firmly controlled by the government. Except for the government gazette *El Peruano*, which was founded in 1820, the oldest newspaper in the 1960s was *El Comercio* (1839) of Lima. Government control was the rule.

9. Bolivia.—In 1825, the year in which the name of Alto Perú was changed to Bolivia, the *Gaceta de Chuquisaca* and the *Cóndor de Bolivia* were founded in the capital, Chuquisaca, later renamed Sucre. Bolivian newspapers, chiefly owned by political factions, were unstable until some time after the adoption of the press law of 1925. The oldest daily in the 1960s was *El Diario* (1905) of La Paz. Under the Paz Estenssoro regime, which came into power in 1952, there was a severe censorship.

10. Brazil.—Brazil's first weekly newspaper was the official *Gazeta do Rio de Janeiro* (1808), which in 1823 became *Diario do Govêrno*. The country's oldest paper in the 1960s was *Diário de Pernambuco* (1825) of Recife. Founded in 1827 was *Jornal do Comercio* of Rio de Janeiro, which, though its circulation was less than those of most other papers in the capital in 1955, had long enjoyed a high reputation and influence as a conservative journal.

With the fall of the empire in 1889 there was a rapid development of newspapers, and in the next 20 years the number of papers and periodicals increased from about 600 to 1,000. By the 1960s there were well over 200 dailies.

The largest paper in Brazil in the 1960s was *O Globo* (1925) of Rio de Janeiro, which claimed a circulation of over 200,000 for its daily edition. Other leading Rio papers were *Jornal do Brasil* (1889), *Correio da Manha* (1901) and *O Jornal* (1919). Perhaps the outstanding paper in São Paulo was *O Estado de São Paulo* (1875). *Diários Associados* had become a strong group of 24 daily papers and 14 radio stations spread widely over the country and including such large papers as *Diário da Noite* (1929) and *O Jornal* in Rio, *Diário da Noite* (1925) in São Paulo and *Diário de Pernambuco* in Recife.

11. Argentina.—*El Telégrafo* (1801–02), the first newspaper

published in Argentina, came from the Buenos Aires press of Francisco Cabello y Mesa, a printer who had already engaged in journalism in Lima, Peru. It was followed by a few other papers in the first decade of the century and, after the first national government was established in 1810, by an official *Gaceta* (1810–21). The chaotic period which preceded the Juan Manuel de Rosas regime (1829–52) brought out many small, vituperative political sheets, but Rosas limited the regular Argentine press to a few papers which were forced to confine themselves to commercial news and official documents. Meantime, Argentine journalists took refuge in other South American countries, there to spread their doctrines of liberty and reform. After the fall of Rosas many of these men returned and renewed the conflicts of political journalism

The modern Argentine press began in the 1860s. *La Nación Argentina* was founded in 1862 but ceased publication in 1869. In 1870 one of its regular contributors, Argentine patriot and president Bartolomé Mitre, founded a new daily, *La Nación*, which eventually became one of the great South American newspapers. In 1869 José Clemente Paz founded *La Prensa*, which was to win similar fame. *La Capital*, begun in Rosario in 1867, completes the trilogy of great Argentine dailies still being published in the 1960s.

La Prensa, long considered one of the world's great newspapers, had the largest circulation (480,000) of any Spanish-language newspaper in the world in 1950. Still owned by the Paz family, it had become famous for its voluminous world-news reports, for its remarkable classified advertising section, for its editorial independence and for its special public services. In 1951, however, *La Prensa* was seized by the government, and was not returned to Alberto Gainza Paz, the publisher, until the fall of the Perón regime in 1955. *La Prensa*'s circulation in the 1960s was about 280,000.

La Nación also had strong international news coverage and gave much attention to technical and transportation problems. Its circulation in the 1960s was about 240,000 for the daily edition and about 300,000 for the Sunday edition. *La Razón* (1905) and *Crítica* (1913) were also important Buenos Aires dailies. There were more than 150 dailies published in Argentina, including a considerable foreign language press in Buenos Aires.

12. **Uruguay.**—The publication of Uruguay's first paper was occasioned by the brief British occupation of Montevideo in 1807; it was an English-Spanish sheet called *La Estrella del Sur*. Many papers, chiefly political, appeared during the troubled history of the country; probably the longest life was that enjoyed by *El Telégrafo* (1850–1931). José Batlle y Ordóñez founded *El Día* in 1886. The above-mentioned papers were published in Montevideo, where the greater proportion of daily papers in Uruguay were still situated in the 1960s. Leading morning papers were *El Día* and *El País* (1919), and the chief evening papers were *El Diario* (1923) and *El Plata* (1915), the latter affiliated with *El Día*. There was much government control.

13. **Paraguay.**—Journalism in Paraguay dates from the middle of the 19th century, though it was irregular until about 1898. There are fewer than ten dailies published in the country; the largest in the 1960s were *La Tribuna* (1925), *El País* (1923) and *Patria* (1946), all published at Asunción.

14. **Chile.**—The earliest of Chile's papers was *La Aurora de Chile*, issued in 1810 at Santiago. *El Mercurio* was founded at Valparaíso in 1825 and *La Unión*, another important paper. was established in the same city in 1885. In 1902 Agustín Edwards, owner of Valparaíso's *El Mercurio*, founded another morning paper of the same name in Santiago; this chain eventually came to include two evening papers in the capital and one in Valparaíso. The *Santiago Mercurio* had the largest circulation of the Chilean dailies (about 125,000 for the daily edition in the 1960s). *La Nación* (1917) was government owned. (F. L. Mt.; X.)

IX. ASIA

1. **The Middle East, Afghanistan and Nepal:** *Syria.*—There were 20 Arabic dailies published in Damascus in the early 1960s. The leading papers were *Al-Nasr, Al Ayamm, Sada Alam* and *Al Talia*. Among the provincial papers, the more important were *Al Watan* and *Barq al-Shemal* published in Aleppo.

Lebanon.—In the early 1960s there were 27 dailies published in Beirut of which 3 were in French and 2 in English. The leading dailies in Arabic were *Al Nahar* and *Al Jarida*, in French *L'Orient* and in English *Daily Star*.

Israel.—The first Hebrew daily paper in Palestine was E. B. Yehuda's *Haheruth* (1909–15). With the establishment of Israel in 1948, Tel Aviv became an active newspaper centre. In the early 1960s, there were 24 dailies, 14 in Hebrew and the rest in Yiddish, Arabic, German, English, French, Polish, Hungarian, Bulgarian and Rumanian. The largest of these papers (circulation 73,000) was a tabloid called *Ma'ariv* (1948). Oldest of them was *Ha'aretz* (circulation 39,000), founded in Egypt in 1915, moved the next year to Jerusalem and later to Tel Aviv. Two other leading papers were *Haboker* (1934) and *La-Merhav* (1954). The others were party papers, most important of which was *Davar* (circulation 40,000), a Socialist organ founded in 1925. The *Jerusalem Post* was the only English-language paper.

Jordan.—In the early 1960s there were six Arabic dailies, including two at Amman and four in Jerusalem. The leading papers were *Falastin, Al-Diffa* and *Al Jihad*. *Jerusalem Times* was a leading paper in the English language.

Iraq.—The first daily newspaper in the country was in English, the *Baghdad Times*, founded in 1914; in 1920 it became the *Iraq Times*. In the early 1960s there were 16 dailies. The leading Arabic dailies were *Al Zaman, Al Akhbar, Al-Belad, El Thawra, Al Ahd Al Jadid* and *El Mustaqbal*.

Iran.—Though there were earlier newssheets concerned with court events, the first regular newspaper in Persia was *Rúznáma*, an official gazette established in Teheran in 1851. With some changes in title, this journal continued for many years, and the modern official daily *Iran* may be said to be descended from it. The first Persian daily was *Khuldsatul-Hawádith* (1898), a two-page paper, printed on one side from type and lithographed on the other. Though typography had been introduced into Persia as early as 1817, it was superseded by lithography during most of the last half of the 19th century.

Many short-lived political papers were published during the chaotic World War II period, some of which continued after the re-establishment of the national sovereignty in 1947. In the early 1960s there were 38 dailies of which 23 were published in Teheran. The leading papers were *Ettela'at* (1924) with news editions in English and French, the *Kayhan* with an English edition *Kayhan International*. Other papers in English and French were respectively *Teheran Journal* and *Le Journal de Téhérán*.

Saudi Arabia.—There were two dailies, *Al Bilad* published in Jidda and *Um Al Quarah* in Mecca.

Afghanistan.—In the early 1960s there were 15 dailies. The papers with the largest circulation were *Anis* (30,000) and *Islah* (15,000). *Kabul Times* was the English language paper.

Nepal.—There were in the early 1960s five dailies in the Nepalese language: *Hal Khabar, Nepal Samachar, Samaj, Naya Samaj* and *Gorkha Patra*. Another daily, *Motherland*, was published in the English language.

2. **Southeast Asia:** *Burma.*—Only about a dozen daily newspapers were published in Burma before World War II, but that number had trebled by 1948. The oldest paper was *Hanthawaddy* (1889). The Burmese press was stimulated by national independence and, as a result of general instability prevailing elsewhere at the time, became concentrated in Rangoon where, in the early 1960s, there were 21 dailies. The leading newspapers were *Bama Khit* (36,000), *Hanthawaddy* (18,000), *Htoon Daily* (12,000), *Mandaing* (10,000) and *Rangoon Daily* (24,600). There were three dailies in English: the *Guardian* (5,500), the *Nation* (18,000) and the *Burman* (5,000). Other languages represented in the press were Chinese and the Indian languages Hindi and Tamil.

Thailand.—In the early 1960s there were 11 dailies, including 8 in the Thai language, 2 in English and 1 in Chinese. The largest of these papers (circulation 35,000) was the Thai paper *Sieng Ang Tong*. Other leading papers were *Pim Phai, Siam Rath,*

Sarn Seri, *Chaothai* in Thai language, *Bangkok Post* and *Bangkok World* in English and *Sin Sian Yit Pao* in Chinese.

Cambodia.—There were in the early 1960s five dailies, including one in the French language. The leading papers were *Kampuchea*, *Meatopum*, *Neak Cheat Niyun* and *La Dépêche du Cambodge.*

Laos.—There were in the early 1960s two dailies, *Pachaninhom* and *Siengmahason.* There was also a daily publication in French, *Bulletin Quotidien lao Presse.*

Republic of Vietnam.—In the early 1960s there were 28 dailies —16 in Vietnamese, 10 in Chinese, 1 in French and 1 in English. The leading Vietnamese papers were *Saigon Moi* and *Tieng-Chuong.* The paper in French was *Journal d'Extrême Orient* and in English, the *Times of Viet Nam.*

Democratic Republic of Vietnam.—The daily with the largest circulation was *Nhen Dan*, official organ of the ruling Lao Dang party. Two other leading papers were *Thu Do* and *Thoi Moi.*

Indonesia.—A newspaper called *Batavaise Nouvelles* was published in Batavia, Java, as early as 1744–46 as a small two-page weekly. Other government gazettes appeared as the colony passed from the French to the Dutch, and then to the English and back to the Dutch. The *Bataviasche Courant* was begun in 1816, changed to *Javasche Courant* in 1828, and continued for more than a century. Continuous struggles with censorship marked the development of the press in the Netherlands Indies.

During the first years of independence, the press developed quickly. In the early 1960s there were 103 dailies with a total of over 400,000 copies. Of these 22 appeared in Jakarta with a circulation of about 250,000. The leading papers were *Suluh Indonesia*, *Merdeka*, *Berita Indonesia*, *Harian Rakjat* of the Communist party and *Duta Masjarakat*, organ of the Islamic party, Nahadul Ulema. There were two dailies in English, *Indonesian Observer* and *Indonesian Herald* and one in Chinese, *Tay Kong Siang Poo.*

3. The Philippines.—The pioneer of the Philippine press was *Del Superior gobierno*, a sheet devoted to European news, published in Manila, 1811–12. The first daily was *La Esperanza* (1846–49). The government's official gazette was founded in 1848 as *Diario de Manila.* The leading paper for many years was *El Comercio* (1858–1925). After 1888 a greater liberality in the censorship and the development of political groups, chiefly nationalist in character, resulted in the establishment of a large number of papers, most of which were small and short lived. The first paper in the Tagalog language was *Patnubay Nang Catolico* (1890).

The *Manila Times*, first U.S. daily in the islands, was founded in 1898 and became a leading paper in circulation and influence. *La Independencia* (1898) became the leading organ of the Emilio Aguinaldo insurrection and was moved from place to place until captured by the U.S. forces.

In World War II all Manila newspaper plants were destroyed by the Japanese. Following the liberation and the establishment of the republic the Manila and provincial press was greatly expanded. In the earlier 1960s there were 12 dailies. Three were in Tagalog (the most important being *Taliba* and *Bagong Buhay*), seven in English (the most important being *Manila Times*, *Philippines Herald* and *Evening News*), *El Debatte* was in Spanish and *Fukien Times* in Chinese. The *Manila Times* had the largest circulation.

4. China.—The first newspaper in China and, if all the claims that have been made for it are accepted, the first newspaper in the world, was a court gazette which began during the T'ang dynasty (A.D. 618–906) and was used as a means of communication between officials. It was continued in the Sung dynasty (960–1279), and early in that period it began appearing at regular intervals and achieved a considerable circulation among Chinese scholars. For title it took the term *Ti-pao*, from *ti*, "palace," and *pao*, "report," a word which had been applied to the earlier bulletins; it was sometimes called *Ti-chan*, or "Court Reading-Matter." In the Ming dynasty (1368–1622) the title of this gazette was changed to *Tungchengsee.* In the last reign of the Ming dynasty, that of Zung Cheng (1628–44), the bulletins, which had hitherto been either handwritten or printed from blocks, began to be printed from movable wood type. During the Ch'ing dynasty (1644–1912) the bulletins were continued under the name *King pao* ("Peking Gazette"). The series was allowed to perish with the Manchus after 1912.

Similar official gazettes sprang up in the provinces under Manchu rule, and gazettes by the various ministries began in 1900. But newspapers for the general public, as apart from gazettes for officialdom, did not begin in China until the 19th century, and then they were translations or imitations of the English-language press which had been established in that country by commercial and missionary agencies.

James Matheson's *Canton Register* (1827–43) was the first English paper in China; when Hong Kong became British, it was transferred to that city and became the *Hongkong Register* (1843–59). Other papers were published in Canton and Hong Kong, and in 1845 the famous *China Mail* was founded in the latter city, with Andrew Shortrede as editor; it became a daily in 1876. The *North China Herald* was founded in Shanghai in 1850; in 1864 it was made a daily under the new title, *North China Daily News.* The *China Press* was founded in Shanghai in 1915 by a group of Americans, and was edited for a time by John B. Powell.

In 1858 Wu Ting-fang suggested Chinese translations of the *China Mail;* the result was the first Chinese paper for the general public, *Chung Ngoi San Pao.* The most important paper founded for the Chinese before the crisis of 1895 was *Shun Pao*, established at Shanghai in 1872 by Frederic Major, an Englishman. At the time of the Chinese revolution in 1911 it was sold to Sze Liang-zay, who made it prosperous and influential before his assassination in 1934. Sze also owned, after 1929, *Sin Wan Pao* (1893).

A period notable for the founding of many revolutionary journals representing various reform movements began in 1895, after the defeat of China in the Chino-Japanese War. These papers had much to do with bringing about the revolution of 1911. After that, the free speech guaranteed in the provisional constitution was an invitation to hundreds of young Chinese to start journals, many of which were short lived. The severe press laws of 1914 cut off most of the newspapers, but in the years 1918–20 the "literary revolution" and the "student movement" again gave rise to a multitude of journals. In 1921 it was reported that more than 1,000 publications were appearing in China, about half of them daily newspapers.

Sun Yat-sen's regime in Canton was especially favourable to development of the press, and the nationalist revolution of 1927 marked the beginning of another new era in the publication of newspapers in China. By 1948 there were, according to government estimates, about 1,800 newspapers, more than half of them dailies, in the entire country.

Aside from a few well-established and influential papers, most of the dailies were small in size and circulation. Many were party organs, often representing small groups. No little venality and unreliability existed among such papers. The press law of 1914 continued throughout Pres. Chiang Kai-shek's administration to impose a stern censorship; by 1948 it was almost equally severe on English-language and Chinese papers.

During World War II Japanese occupation of the coastal cities drove most of the great Chinese papers inland, but they were quick to recover in 1945–48. *Shun Pao* ("Shanghai Gazette") returned to Shanghai from Hong Kong; and its sister paper, *Sin Wan Pao* (the "News Gazette"), achieved an all-time Chinese circulation record of 350,000, largely through its commercial news. National circulations grew as never before, through the establishment of multiple-city editions. Thus the Kuomintang organ *Chung Yang Jih Pao* ("Central Daily News") was published in Nanking, Shanghai, Chungking and several other cities.

It was estimated that there were 36 dailies published in the early 1960s under the aegis of the Chinese People's Republic: the more important among them appearing in Peking and Shanghai. The most important was the *Jen Min Jih Pao* (People's Daily) published in Peking. The *Ta Kung Pao* (Impartial Gazette), was the founded in Tientsin in 1902 but now published in Peking,

only paper which survived the nationalist regime. It specialized in foreign affairs. *Sin Wan Jih Pao* and *Chieh Fang Daily News* were published in Shanghai. The *Hsin Hua* or New China News agency, which was the section of the ministry of information, had a monopoly in the collection and distribution of news.

5. **Japan.**—Newssheets called *yomiuri* appeared in Japan late in the 17th century. They were printed from blocks and were sold by vendors who attracted customers by reading the news aloud; hence the name, which means "selling by reading aloud," and which later became the title of one of the greatest of Japanese newspapers. The first newspaper was the English-language *Shipping List and Advertiser* (1861) of Nagasaki, which was soon moved to Yokohama to become the *Japan Herald*. Several other papers in English were begun in the 1860s. The first periodical in the Japanese language was a series of official translations of foreign news, issued monthly, of which the earliest was *Batavia Shimbun* (1862), derived from a Dutch paper in Java. The first Japanese newspaper for general circulation was the *Shimbunshi* (1864), established by Joseph Hikozo. This paper was followed by other Yokohama papers in Japanese, published by Englishmen and Americans.

But it was in 1868, the year of the Meiji restoration, that Japanese journalism really began. In that year 16 papers, in Tokyo, Osaka, Kyōto, Yokohama and other cities, were founded. This development continued despite strict censorship, many imprisonments of editors and occasional forcible suspensions.

The *Tokyo Nichi-Nichi* was founded in 1872, with the famous Genichiro Fukuchi, dramatist and educator, as its editor. In 1906 Hikoichi Motoyama, manager of one of the great industrial syndicates which were growing up in Japan, bought the *Nichi-Nichi* and made it an associate of the *Osaka Mainichi*, which he had owned for many years. The latter paper was founded as *Osaka Nippo* in 1876, but Motoyama rechristened it *Mainichi* when he bought it in 1888. These two papers set a great pace in enterprise, foreign correspondence and a degree of sensationalism. Each paper ran its circulation to more than 1,000,000 before World War II. Provincial papers were founded or purchased, including *Kyushu Mainichi* at Moji. In the war consolidations of 1942–43 these were all lost except the Kyushu paper. From the ordeal, however, the Tokyo and Osaka papers emerged with nearly 1,500,000 circulation each, and the one in Kyushu with more than 500,000.

The *Osaka Asahi* was founded in 1879 by Ryuhei Murayama, one of the greatest journalists of the Meiji era. It flourished, winning respect for its careful news coverage and progressiveness, and in 1888 the *Tokyo Asahi* was begun. Establishing connections with the *Times* of London, the *New York Times* and the Associated Press, these papers built up circulations of more than 1,000,000 each, covering the island of Honshu; in 1935 the Asahi company established the *Seibu* (Kokura) *Asahi* on the southern island of Kyushu. In the postwar period the Tokyo and Osaka papers each had about 1,500,000 circulation, and the Kyushu paper more than 500,000.

Founded in 1874, the *Yomiuri* of Tokyo had made a success in the 1930s by its emphasis on sports, finance and politics. In 1942 it was consolidated with *Hochi*, founded in 1872 by friends of Marquis Okuma and later owned by Seiji Noma, the "magazine king." In the war years it gained on its competitors, reaching nearly 2,000,000 circulation in 1944.

By 1937 the Japanese press, despite a period of stern repression preceding the constitution of 1889, had reached a very prosperous position. Beginning about 1889, it had largely changed over from the system of party journals to that of more or less independent mass-circulation papers. In 1937 there were 1,200 dailies and 600 weeklies in Japan. In the next two years, as the government tightened its control, there was a small decline; in 1940–41 came a reduction of 36% annually; in 1942, at government "suggestion," wholesale combinations were made which left one daily in each district outside the largest cities. This brought the total down to 53. After the end of the war in 1945, the number rose rapidly, and in early 1960s the Japan Publishers and Editors association (*Nihon Shimbun Kyokai*) reported a membership of 101 newspapers with a total circulation of 37,000,000.

Many newspapers suffered damage to their plant during the war. Under the administration of the supreme commander for the Allied powers (SCAP), newspaper management was "purged," and a precensorship set up which operated until July 1948.

Some papers have reduced the 9,000 ideographs known to the learned to fewer than 2,000 used in their columns, in order to bring their articles and editorials within the reading knowledge of the masses, using the syllable alphabet known as *kana* as an aid.

A distinctive feature of the Japanese press is that the leading newspapers are concentrated in Tokyo and Osaka. Approximately 45% of the circulation was accounted for by four national newspapers. *Asahi Shimbun, Mainichi Shimbun, Yomiuri Shimbun,* the "big three," and *Sangyo Keizai*, an economic daily, all centred in Tokyo. Counting the morning and evening editions separately, the "big three" alone had a combined circulation of around 12,000,000. They sold only about 5% of their copies on the street, while *Tokyo Shimbun* (representing a wartime consolidation of *Miyako Shimbun*, founded in 1884, and *Kokumin Shimbun*, founded in 1890) sold most of its nearly 500,000 circulation from pavement stands. Two other notable Tokyo papers were *Nippon Keizai Shimbun* (1876), the "Wall Street Journal of Japan," and *Japan Times* (1897), an English-language daily edited by Japanese. This paper, merged with *Japan Advertiser* (1890) as a wartime measure, was published for a time as *Nippon Times*. There were also English editions of *Asahi, Mainichi* and *Yomiuri*, *Mainichi's* English edition appearing in both Tokyo and Osaka.

Other leading newspapers were: *Chubu Nippon Shimbun*, Nagoya; *Nishi Nippon Shimbun* in Kyushu; and *Hokkaido Shimbun* in Sapporo, Hokkaido. Other dailies of interest were: *Kahoku Shimpo*, Sendai; *Shinano Mainichi Shimbun*, Nagano; *Niigata Nippo*, Niigata; *Kyōto Shimbun*, Kyōto; *Kobe Shimbun*, Kobe; *Sanyo Shimbun*, Okayama; *Chugoko Shimbun*, Hiroshima; *Kumanoto Nichinichi Shimbun*, Kumamoto; *Ehime Shimbun*, Matsuyama; and *Kochi Shimbun*, Kochi. The growing interest in sports was catered for by one daily devoted wholly to photo journalism.

The fact that four national newspapers accounted for nearly half of the total circulation has resulted in a unique pattern of news gathering and editing services. The *Asahi Shimbun* and *Mainichi Shimbun*, for instance, had four main offices in the three principal cities of Japan, Tokyo, Osaka and Nagoya, as well as in a city of northern Kyushu, and each of these main offices had its own editorial, business and mechanical facilities. This necessitated the employment of a large staff. The *Mainichi Shimbun* at the beginning of the 1960s employed more than 5,000 men, about a quarter of them on the editorial side. Employment on a newspaper was generally a lifetime position and newspaper labour unions were strong.

The leading news agency in the early 1960s was Kyodo Tsushin Sha (Mutual Wire-Service company), the descendant of the old government-subsidized Domei, founded in 1936. The Jiji Press, also a by-product of the defunct Domei, specialized in economic and financial matters.

6. **Other Countries:** *Republic of Korea.*—Of the 13 dailies at the beginning of the 1960s, the leading papers were *Dong-A-Ilbo*, and *Seoul Shin Mun*.

Democratic People's Republic of Korea.—There were seven principal dailies in the early 1960s—all connected with political groupings and government.

Formosa.—In 1961 there were 29 daily papers appearing at T'ai-pei and other towns in Formosa, *Hsing Sheng Pao* being the most important. There were two dailies published in English.

(A. P. R.; Jo. K. B.)

X. AFRICA

A UNESCO survey in 1961 established that there were 231 daily papers in Africa including British Commonwealth countries, with a total circulation of 3,000,000. This represented an average of 1.2 copies per 1,000 inhabitants, the lowest of any region in the world. The majority of all papers were concentrated in 14 countries: Algeria, Ethiopia, Ghana, Kenya, Morocco, Nigeria, Rho-

desia, Senegal, Sierra Leone, South Africa, Tanganyika, Tunisia, Uganda, United Arab Republic. In seven countries there were no daily papers other than sheets done by roneo, a process similar to mimeograph. In 15 countries, with a combined population of 12,000,000, there were no daily papers at all. Sub-Sahara territories accounted for only 125 dailies with a circulation of 900,000 copies.

There were in all territories 839 nondaily papers (including weeklies and bi- and tri-weeklies) and 1,395 periodicals. Sub-Sahara territories circulated 330 of the nondailies and 680 of the periodicals. In East, Central and South Africa the press was largely European- or Asian-owned; many of the papers in French-speaking Africa were owned by French companies. The trend in the 1960s was toward state-owned newspapers in newly independent countries, though this did not exclude privately owned papers except in a few countries. A large proportion of papers and periodicals were organs of political parties and trade unions. Religious missions owned several important periodicals; the *African Challenge* (Lagos), published in several languages by the Sudan Interior mission, had a monthly circulation of 115,700 copies throughout the continent; an illustrated Catholic monthly, *Présence Chrétienne* (Togo), and *The Truth*, a Muslim monthly published in English by the Ahmadiya Mission of Nigeria, were both widely distributed. Minority communities often provided their own papers.

In the 1960s there was a growing tendency toward producing papers for regional or continent-wide distribution. Outstanding examples in the field of reviews and magazines were *Jeune Afrique*, a Tunisian weekly; *Central African Examiner*, a Rhodesian monthly; *Afrique Nouvelle*, a Dakar weekly; the *Scribe* and the *Arab Review*, two Cairo official publications.

The most successful mass circulation papers were *Drum* (250,000), published in three regional editions; *Zonk*, published in Johannesburg; *Parade*, published in Central Africa; and *Bingo*, published in Dakar with three different editions for French-speaking Africa.

Although the big circulation papers were mainly published in European languages, the vernacular press was, in the early 1960s, becoming increasingly important. Of the 163 languages used by papers and periodicals, 145 were African; in one country more than 25 African languages were used. The most frequent language was Swahili with 60 newspapers and periodicals in 7 countries; Arabic was used in fewer papers but in 11 countries; Hausa was used in 6 countries.

1. United Arab Republic.—There were 21 dailies published in the early 1960s. Of these, 6 were in Arabic and had a circulation of 570,000, out of a total circulation of 652,000. There were also 27 nondailies, 13 in Arabic, and 31 periodicals, 20 in Arabic. The largest daily was *Al Ahram* (established 1875) with a circulation of 200,000 (300,000 on Fridays); *Al Akhbar* followed with 180,000, and *Al Gomhouria*, "the paper of the revolution," was third with 150,000. The largest evening paper was *Al-Messaa* (12,000), the leading political weekly was *Akhbar Elyom* (250,000), the biggest illustrated weekly *Al Mussawar* (40,000); the next biggest *Akher Saa* (30,000) appeared in co-operation with *Al Akhbar*. The most popular weekly, *Sabah El Kher* (50,000), appeared in co-operation with *Rose El Yousef* (50,000). There was also a woman's weekly, *Hawaa* (80,000). The *Arab Observer* and *Scribe* were both official magazines.

Under the law of 1958 no newspaper could be privately owned; all papers were transferred to the national union and were controlled by the staff. Half the profits went to the workers, the other half to future development. Censorship was abrogated under the law of 1958. Newspapers required a licence from the national union.

2. Other North African Countries: *Libya.*—The daily *Trablus el Gharb* was government-owned and published in Arabic, while the privately owned *Il Giornale di Tripoli* was published in Italian. Of the eight nondailies, two were government-owned and in Arabic, three privately owned and in Arabic and three in English and privately owned. Press laws were fairly stringent and suspension of papers occurred periodically.

Tunisia.—In the early 1960s two dailies were published in Arabic and two in French. Their combined circulation of 80,000 represented 20.8 copies per 1,000 inhabitants. There were also two nondailies, one in Italian and one in French, and five periodicals (four in Arabic, and one in French). The largest daily was the French *La Presse de Tunisie* (30,000). The government organ, *Al-Amal*, had a circulation of 20,000. *Jeune Afrique* (80,000), a French weekly, included all Africa in its scope.

Algeria.—Nine dailies were published in the early 1960s in French and Arabic; with a total circulation of 300,000, their sales averaged 30 per 1,000 population. Two nondailies and 192 periodicals were also published.

The Algerian press was greatly disrupted by the fight for independence from France, 1954–62, and its aftermath. Four dailies were published, *Alger Républicain*, *Le Peuple*, *Alger ce soir* and *La République* and a weekly *Révolution Africaine*. All supported the governing party, the National Liberation front (F.L.N.).

Morocco.—There were seven dailies in the early 1960s with a combined circulation of 112,500 representing 90 copies per 1,000 inhabitants. Among them was *Espana* (Spanish 35,000). *Le Petit Marocain* (French 30,000) and *La Vigie Marocaine* (French 30,000) were both published by the Mas group; *La Nation Africaine* (French 5,000) was published by the government; *Al Alam* (Arabic 5,000) was published by the Istiqlal party; *At Tahrir* (Arabic 5,000) was published by the National Union of Popular Forces. There were also 19 nondailies and 100 periodicals.

3. French-Speaking Countries.—Freedom of the press, based largely on the French law of 1881, was guaranteed in the constitutions of all African territories that are members of the French Community, though stringent penalties are generally provided. However, the press in the early 1960s was carefully watched over by the governments; indirect pressure was strong, and direct action was not unusual.

Except for papers and periodicals financed by a government or controlled by a political party, most were owned by companies in which Europeans held the major share.

Cameroon Republic.—There was one daily in French with a circulation of 10,000, representing 3 copies per 1,000 inhabitants. There were also five nondailies and 17 periodicals.

Central African Republic.—There was one daily in French with a circulation of 1,000 representing 9 copies per 1,000 inhabitants. There was also a nondaily.

Chad.—There were two dailies in French; their combined circulation of 1,200 represented 5 copies per 1,000 inhabitants. There was also a periodical.

Republic of Congo.—There were three dailies in French with a joint circulation of 1,100, representing 1 copy per 1,000 inhabitants. There were also a nondaily and three periodicals.

Dahomey.—There were two dailies in French; their joint circulation of 3,000 represented 2 copies per 1,000 inhabitants. There were also two nondailies and three periodicals.

Guinea.—The government published the only daily and the press was subject to direct government control. There were also a nondaily and three periodicals.

Ivory Coast.—There was one daily in French with a circulation of 9,400 representing 3 copies per 1,000 inhabitants. The government published a nondaily and there were also two periodicals. Press control was exercised through a law of 1959; it was invoked against local journalists and was also used to keep foreign papers out of the country.

Malagasy Republic.—There were 17 dailies with a combined circulation of 20,000 representing 4 copies per 1,000 inhabitants. There were also 28 nondailies and 16 periodicals.

Mali.—The government published a mimeographed daily bulletin. There were three dailies, the main one being *L'Essor* (4,500), the government party weekly. A statute of 1954 provided for press legislation.

Mauritania.—The government published a nondaily information bulletin in Arabic.

Niger.—There was one daily cyclostyled bulletin in French; its circulation of 1,000 represented 4 copies per 1,000 inhabitants. The press was controlled by a decree of 1959, which stipulated

that every issue of a paper should be deposited with the authorities 12 hours before publication.

Senegal.—There was one French daily, *Paris Dakar* (daily since 1935). With a circulation of 20,000, it sold 8 copies per 1,000 inhabitants. There were 7 nondailies and 41 periodicals, including information publications, government publications, party and trade union organs, etc.

Somaliland (French).—There were one nondaily with a circulation of 700 and one periodical.

Togo.—There were two dailies with a joint circulation of 1,650, one of them a government daily, *Togo Press;* the other was the *Togo Observateur.* There were also six nondailies and two periodicals including the Catholic monthly *Mia Holo* (1920). The press was controlled by a law of 1959 which included the stipulation that two copies signed by the editor must be deposited with the authorities two hours before publication.

Upper Volta.—The government published a cyclostyled daily bulletin with a circulation of 600, representing 6 copies per 1,000 inhabitants. They also published a weekly bulletin. The press was controlled by a law of 1959, based on the French law of 1881 but providing for stiffer penalties.

4. Portuguese Territories.—*Angola.*—There were in the early 1960s four dailies with a combined circulation of 23,000 representing 5 copies per 1,000 inhabitants. There were also seven nondailies including *Diario da Manha*, the official organ of the Portuguese National union. Seventeen periodicals were published, and a strict form of censorship was maintained.

Mozambique.—There were four dailies with a combined circulation of 20,000 representing 3 copies per 1,000 inhabitants. Five nondailies and 25 periodicals were published.

Guinea (Portuguese).—One daily was published; its circulation of 1,100 represented 1.9 copies per 1,000 inhabitants.

5. South Africa.—The South African press was in the early 1960s the largest and in many ways the most vigorous in the continent. Of the 19 dailies, 13, including those with the largest circulations, were in English and 6 in Afrikaans. Their combined circulation reached 897,000, representing 61 copies per 1,000 inhabitants. The combined sale of nondailies was 950,000; 25 periodicals were published. The largest newspaper group was the Argus S. African Newspapers Ltd., which controlled the *Star* (Johannesburg), *Cape Argus* (Cape Town), *Daily News* (Durban), *Friend and Goldfields Friend* (Bloemfontein) and *Pretoria News.* The other leading papers were the *Rand Daily Mail* (Johannesburg), *Cape Times* (Cape Town), *Natal Mercury* (Durban), *Evening Post* and *E. P. Herald* (Port Elizabeth). The leading Sunday papers were the *Sunday Times* and *Sunday Express* (both Johannesburg). A new paper, the *Sunday Chronicle* was launched in Johannesburg in 1964 by the Argus group.

The Afrikaans newspapers, though relatively small in circulation, were politically important. The prime minister sat on the boards that controlled all the major Afrikaans newspapers in the Transvaal: *Die Transvaler* and *Die Vaderland* (both dailies) and *Dagbreek* (Sunday). Other important Afrikaans papers supporting the government were *Die Burger* (Cape Town), *Die Volksblad* (Bloemfontein) and *Die Oosterlig* (Port Elizabeth).

Papers catering largely for Africans have assumed new importance particularly after the Republic was formed. The *World*, formerly a weekly, became the first African daily using both English and vernacular languages. The *Golden City Post*, a Sunday paper with a circulation approaching 100,000, was the companion paper to the illustrated monthly *Drum.*

Publication of the press commission report resulted, in 1962, in the Newspaper Press union agreeing to voluntary control through a board which has accepted its own code of conduct. In 1964 the press commission proposed official control but action on this recommendation was deferred. A dozen statutes affect the operation of the press; these include the Public Safety act, the Native Administration act, the Suppression of Communism act, the Official Secrets act, the Prisons act, the Riotous Assemblies act, the Publications and Entertainments act and the Criminal Law Amendment act ("the Sabotage bill"). A deposit of £10,000 was required by all new papers beginning publication.

6. Other Countries: *Liberia.*—The daily *Listener*, Monrovia, had a circulation of 2,000 while the twice-weekly *The Liberian Age* one of 3,000 and the Lorma weekly *Wuzi*, in the vernacular, one of 1,000. The first two of these papers were government subsidized. There were also three periodicals. In theory there was no press censorship.

Sudan.—In the early 1960s there were nine dailies in Arabic and three in English with a combined circulation of 30,000 representing 3.6 copies per 1,000 inhabitants; 13 nondailies and 5 periodicals were published. The press was subject to indirect control through the ministry of information.

Ethiopia.—In the early 1960s three dailies were published in Addis Ababa (two in English, one in French) and two in Asmara (one in Italian, the other trilingual: Arabic, Tigrinya, Amharic). Their combined circulation of 10,000 represented 5 copies per 1,000 population. There were 5 nondailies, including a French weekly in Addis Ababa, and 32 periodicals, among which the *Ethiopia Observer* was of special interest. Government press control was firmly maintained.

Somalia.—One daily was published in Arabic and Italian; its circulation of 2,000 represented 1.5 copies per 1,000 inhabitants. Five nondailies and three periodicals were also published.

Burundi and Rwanda.—Before these two countries received their separate independence in 1962, 7 nondailies were published with a combined circulation of 70,000, representing 15 copies per 1,000 inhabitants; 16 periodicals were also published.

Democratic Republic of the Congo.—In the later 1960s three dailies were published in Kinshasa (formerly Léopoldville), three in Lubumbashi (formerly Elisabethville) and one in Kisangani (formerly Stanleyville). Several weeklies and periodicals were also published. The most important papers were the *Courrier d'Afrique* and *Présence Congolaise* in Kinshasa.

The press was greatly disrupted by events following independence in 1960, and several papers were temporarily suspended by government action.

For African countries in the Commonwealth see *Commonwealth of Nations: Africa,* above. (Co. L.)

XI. THE NEWSPAPER OFFICE

Newspaper offices all over the world differ, just as newspapers differ: Spanish newspapers are more literary, French newspapers are more political than are U.S. newspapers. In the U.S. a big metropolitan daily newspaper office may be in a multistoried building; a small-town weekly newspaper may be in a one-story building with the combined editorial, advertising and business office in front and a print shop in the rear, and two men doing all the work. What follows here is a generalized account of a newspaper office of a metropolitan newspaper in the United States.

A newspaper is produced and distributed by an organization divided, generally, into three major parts: editorial, business and mechanical. The large newspaper is directed by, in addition to these basic operational divisions, or sides, an administrative group, and is aided by a promotion department. Thus the entire organization may be said to have five divisions.

1. Editorial Division.—This is the heart of the newspaper. Its function is the gathering and preparation of news, features and comment; indeed, the editorial side includes everything that goes into the paper except advertising.

Housing arrangements differ in the various offices, but the modern news room is big and inclusive. Prominent in it is the city desk, headquarters for local news coverage. There the city editor directs a corps of reporters and rewrite men; the latter prepare copy from news telephoned in, rewrite stories from earlier editions, etc. More or less under the direction of the city desk are a number of reporters and critics in special fields, such as the theatre, motion pictures, music, churches, schools, books, fashions, etc. These men are often called editors in their particular departments; on the largest papers theirs are full-time jobs, but on most papers they perform these special functions in combination or along with other assignments. Also under the supervision of the city desk is the picture editor, with the staff photographers to whom he gives assignments. Some papers have feature editors, whose duty is to

select from syndicated material or from pieces obtained from reporters attached to the city desk a supply of entertaining or instructive stories known as features. About-town columnists are often connected with the feature desk.

The sports editor may have a staff of several reporters, and perhaps special photographers and columnists are attached to that desk. The financial editor also has reporters for local news, as well as assistants to handle wire reports. The society editor and her staff of reporters deal with social events, meetings of women's clubs, etc. Most of the large papers also have woman's page editors, who produce, from the syndicates and other sources, matter of special interest to women. An increasing number of science editors write special articles on new developments in the sciences. In agricultural regions, many papers have full-time farm editors; and there are oil editors in districts where that industry is of great importance.

An immense volume of material is received by each department from the public relations offices of organizations, government departments and business concerns. Only a small percentage of public relations releases find their way into print, but all are scanned for newsworthiness.

The Sunday editor and his staff have charge of the planning and assembling of features for the Sunday edition. (In England all Sunday newspapers have separate staffs even though they may be owned by organizations possessing a daily.) Attached to his desk are the editors and staffs of any pictorial or feature supplements that originate in the newspaper office.

The editorial page staff is headed by a chief who is usually called editor of the editorial page (or section). The political cartoonist belongs to this staff, and the syndicated public affairs columns pass through their hands.

In the newsroom is located the copy desk, a great U-shaped table at which copy from reporters, feature writers and the teletypes is processed for the printers. This processing includes checking for facts, libelous statements, names, spelling, punctuation, paragraphing, tautology, etc., and the writing of headlines. The copy chief, or slot man, sits inside the "U," whence he can hand out incoming copy to the copyreaders "on the rim." Nearby is the desk of the telegraph editor, who handles the long strips of copy torn from the teletype machines, which receive the reports of the wire news agencies. Through the teletypes pours a stream of reports from abroad, from Washington, from the state capital and from news centres throughout the country. The telegraph editor has the responsibility of selecting from this mass of material the sections that his paper's readers will find most important and interesting.

It must be understood, however, that copy desk functions, like the organization of the newspaper office throughout, differ considerably from paper to paper. For example, the copy chief sometimes doubles as telegraph editor, even on large papers. Sports, society and so on may move their copy across a so-called universal copy desk; on the other hand, those departments (and even state news, city and telegraph in a few cases) may have separate copy desks.

Conveniently situated for the use of newsmen, copyreaders and editorial writers are the paper's reference library and morgue. In the latter are filed thousands of clippings, as well as the paper's own back numbers; innumerable photographs, engravings and mats, from which pictures may be reproduced; and other materials that may be drawn upon for the day's stories, whether the reported events are scheduled or unexpected.

2. Business Division: Advertising and Circulation.—The revenue division of the newspaper has two parts: the advertising department and the circulation department. The financial outgo is also considered as belonging to the business side, but in the organizational chart it comes under the administrative division, considered below.

The advertising department headed by the advertising manager, is divided into three subdepartments according to the types of advertising produced: local display, which sells space to local merchants and helps them prepare their copy; national display, which handles advertising from outside the local trading area, much of it obtained from agencies serving various regions or the whole country; and classified, which takes care of the small ads (wanted, for sale, etc.). The local (or retail) advertising manager directs a force of salesmen, who are assisted in providing attractive copy by a corps of copy writers and artists. The national (or general) advertising manager works with special advertising representatives in the large manufacturing centres and with the advertising agencies. The classified advertising manager directs street salesmen, correspondence salesmen and a group of telephone solicitors, as well as the office's own want-ad clerks. Attached to the advertising department in many newspaper offices is a research bureau, whose director is assisted by interviewers and a clerical force.

The circulation department is composed of several units. City distribution by truck and carrier is central in its duties; also there is distribution by truck in outlying districts, towns and cities, and by mail. Sales and collections are important; carrier boys are often useful in these activities. The circulation manager of a large paper may have under him such supervisors or managers of various divisions, as a city circulation manager, country circulation manager, mail circulation manager and Sunday circulation manager. District and branch supervisors oversee delivery to street salesmen, newsstands, local carriers, motor route carriers and outside country dealers. There are also street and telephone solicitors and subscription agents, as well as collectors, etc. The mailing room superintendent directs a force of mailers.

3. Mechanical Division.—This department has four chief units: (1) the composing room, where copy from the newsroom (or rooms), editorial room and advertising desks is set into type, mainly by Linotype, and made up into page forms; (2) the engraving room, which takes photographs and drawings and makes engravings (cuts) for printing; (3) the stereotyping room, where plates for the presses are cast in molten metal from the page forms; and (4) the pressroom, where the papers are printed, folded, trimmed, counted and delivered to the mailing room for bundling for the trucks and wrapping and addressing for the post office.

A mechanical superintendent usually oversees and co-ordinates this four-part operation. A composing room foreman supervises the force of Linotype operators (or compositors); the machinists who care for the Linotypes; the compositors who assemble the Linotype slugs, hand-set type, cuts, etc., that make up the ads; the proofreaders and correctors of both news galleys and ads; and the make-up men, who put the pages together in forms and who work under the direction of a make-up superintendent. The engraving room has its own foreman, with such assistants as are necessary to process the cuts for news stories, features, advertising and the editorial page. The superintendent of the stereotyping room has a force of stereotypers, who make mats from each form to be placed in the casting mold; the plates from this mold are curved so that they may be locked on the cylinders of the presses. The pressroom foreman directs a group of pressmen, who not only fix the plates on the cylinders but also by accurate mechanical means take care of the necessary feeding of paper and ink to produce a well-printed paper.

4. Administrative Division.—An organization as complicated as that which produces a daily newspaper must be efficiently co-ordinated. This requirement is met by an administrative group that varies greatly in its composition and in the terminology of its personnel from one newspaper office to another. In general, however, it includes the president, publisher, executive editor, managing editor, circulation manager, advertising manager, mechanical superintendent and business manager.

At the head of these is the president of the publishing company or the board of directors. He sometimes carries the title of publisher, or there may be both a president and a publisher. These positions represent the ownership, and the men occupying them generally direct the policy of the paper. Ordinarily there is a large degree of autonomy allowed the editors and managers on the lower levels. The term editor in chief is no longer in common use. Editor is a title often given to the chief of the entire editorial division, though a few papers retain the older custom of calling the editor of the editorial page editor of the paper; indeed, some papers combine the two functions. In a number of instances the

publisher also carries the title of editor. Publisher is the title of the active executive head, however, and the man filling that position keeps in constant touch with all the administrative heads named above.

Under the editor are the executive editor, the managing editor and the news editor. Usually a paper does not have all three of these positions. When it has an executive editor, he is chiefly occupied with the management of the personnel of the editorial division, and then the managing editor has general oversight of the flow of news and features. If there is no executive editor, the managing editor usually works mainly with personnel and a news editor with planning the news and feature program of the day. A news editor commonly has a desk adjacent to the copy desk, so he can keep tab on the copy that is coming in. He is in constant consultation with the city and telegraph editors as well; and, with the make-up editor, he is continually planning and replanning the pages of the next edition as events develop.

The business manager is in charge of all financial outgo. He and his staff attend to payroll and to purchases of paper, ink, metal and other supplies. With the custodian, he takes care of maintenance of the building; with the mechanical superintendent, he keeps up the equipment of machinery. The accounting department may be headed by the treasurer of the publishing company or by the cashier or controller. Here are the auditor and a staff of bookkeepers and clerks. The business manager himself is sometimes called assistant publisher, and he keeps in close contact with all departments and operations of the newspaper office.

5. Promotion Division.—The division devoted to promotion and advertising of the paper to the public works closely with the circulation department, but it also serves other departments. It gives support to the paper's community service projects, striving to create good will and understanding. It is headed by a promotion manager, who may be assisted by copy writers, script writers and photographers or, at any rate, by workers who can help in the preparation of newspaper and direct-mail advertising, radio and television shows, exhibits, etc.

6. The Story of a Story.—It may help to clarify the activities of the newspaper office to trace a news story for an afternoon paper throughout its course from assignment to lockup in its page form.

Reporter Jones receives from his city editor in the morning an assignment to cover a bar association meeting at which, it has been rumoured, Judge X may announce his candidacy for the governorship. Jones is back by 11 o'clock. "He's going to run," he tells the city editor, who then instructs him as to how long his story may be. As Jones pounds it out on his typewriter, it is brought by a copy boy to the desk of the city editor, who looks it over and perhaps calls Jones over to consult about some points in it. Then he places it in a box, from which a copy boy soon carries it to the news editor, who glances over it and hands it to the copy chief, with a few words about the position and display he plans to give it in the next edition.

The copy chief then marks Jones's story with an identifying name, "Judge X," and a number indicating the kind of headlines it is to carry, in conformity with the "play" suggested by the news editor, and turns it over to one of his copyreaders for checking and head writing. After the copy has been edited and the head written and attached, it is sent by pneumatic tube down to the composing room. There the copy cutter, because the deadline for the first home edition is approaching, divides the copy into two "takes" for two of the Linotype operators. Soon the slugs, each carrying in relief letters from which a line is to be printed, and now still warm from the machines, are delivered to the galley bank, together with the original copy. The bank man pulls a proof, which he sends, with copy, by tube to the proofroom. After the proofreaders return the marked proof to the composing room, lines in which errors have occurred are reset, and the new slugs are substituted for those that carried the errors, in a process called correcting the galleys.

Meanwhile, in the newsroom upstairs, the first home edition is taking form under the supervision of the news editor, who must decide on space, position and display of news. The ads have already been in place on the make-up tables downstairs for hours; and the sports, society, editorial and stock-market pages are being made up separately by their own departments. The news editor is assisted by his make-up editor, who is working with dummy sheets for pages on which space allotted to various ads is crossed off. They have an earlier mail edition as a starting point from which to lay out the home edition. In conferences around the news and make-up desks, city, state, telegraph and picture editors have pointed out the stories that could be discarded from the earlier edition and those that are in process for later editions, thus keeping the news editor informed on a constantly changing news picture.

Today a European political crisis, an airplane disaster and the proceedings of a congressional committee are the big stories; but the news editor points out a position on page one below the fold for Judge X's announcement, and the picture editor has dug up a single-column cut of the judge from the morgue to go with it.

At one o'clock the completed dummies of the main news pages are taken down to the composing room by the make-up editor. There the make-up men are bending over rows of steel-topped tables on which lie the page forms to which they now transfer from the galleys the slugs carrying the various stories. The news editor himself comes down to oversee the last phases of the make-up of page-one form, shortening a story here and there to make it fit, with the assistance of a Linotype operator. At last everything is exactly in place, and the sound of the planer and mallet on the form marks the end of the editorial work on page one, with Jones's story of Judge X's announcement. The form is ready to be wheeled to the stereotyping room, and in a matter of minutes it will be on the presses. (F. L. MT.)

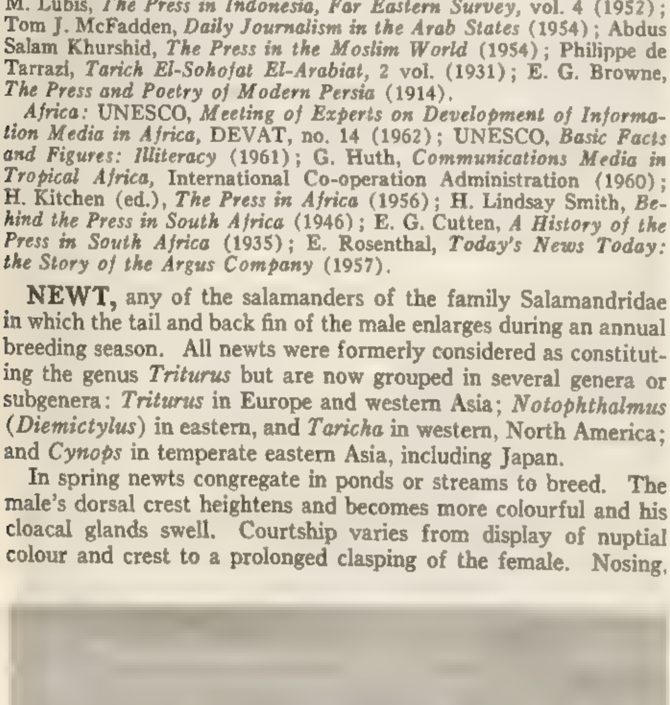
NEWT, any of the salamanders of the family Salamandridae in which the tail and back fin of the male enlarges during an annual breeding season. All newts were formerly considered as constituting the genus *Triturus* but are now grouped in several genera or subgenera: *Triturus* in Europe and western Asia; *Notophthalmus* (*Diemictylus*) in eastern, and *Taricha* in western, North America; and *Cynops* in temperate eastern Asia, including Japan.

In spring newts congregate in ponds or streams to breed. The male's dorsal crest heightens and becomes more colourful and his cloacal glands swell. Courtship varies from display of nuptial colour and crest to a prolonged clasping of the female. Nosing, rubbing and the release of scents presumably stimulate the female to pick up the spermatophore that the male deposits at the mating climax. The spermatophore consists of a large basal gelatinous part and a detachable sperm capsule top that the female removes with her cloacal lips. The sperms free themselves and lodge in glandular folds of the female's cloaca, where the eggs are fertilized a few days later as they are laid.



ISABELLE HUNT CONANT

RED-SPOTTED NEWT (NOTOPHTHALMUS V. VIRIDESCENS)

The female of most newts lays 200 or more eggs, attaching them singly to vegetation, sticks or stones in the water; *Taricha* lays 5–30 eggs, mostly in clumps. The eggs hatch in three to five weeks, and the larvae usually transform at summer's end. Although neoteny (prolongation of the aquatic larval stage) is known, most young newts lead a completely terrestrial life. In the eastern U.S. they are called efts or red efts at this stage. When two to four years old, newts mature and begin their annual or permanent return to the ponds. During the autumn, partial courtship may occasionally take place.

Newts eat earthworms, insects, snails and other small animals. In the water they also ingest amphibian eggs, including their own. They are favourite aquarium animals and are also much used in experimental studies. *See* also AMPHIBIA; SALAMANDER; and references under "Newt" in the Index. (G. B. R.)

NEW TESTAMENT: *see* BIBLE.

NEW THOUGHT, a term used to characterize an important religio-metaphysical healing movement which received its first impulse from Phineas Parkhurst Quimby (*q.v.*), the first person, certainly in America, to have arrived at the conclusion that all illness is basically a matter of the mind, of mistaken belief. His healings were therefore accomplished by correcting the patient's wrong belief. Many came to him for healing, among them, in the early 1860s, four persons who themselves became famous healers.

One of these was Mary Baker Eddy (*q.v.*), who later founded Christian Science. Just how much of her teaching she derived from Quimby is a moot question; according to Christian Science belief her *Science and Health* was divinely revealed personally to her. Warren Felt Evans (1817–89) became the first articulate exponent of the Quimby point of view, contributed to its further development, and spread it through his several widely read and influential books; but he left no organization.

It was Julius A. Dresser and Annette Seabury, later his wife, who first gave organized form to what may be called New Thought as over against Christian Science. This has since taken many forms, all loosely recognized as New Thought in general belief and practice but differing widely one from another at points. Among these have been Divine Science, Unity (*q.v.*) School of Christianity, Home of Truth, Church of the Truth, Religious Science and others, most of which have been at one time or are now united in a rather loose federation known as the International New Thought Alliance.

Differing rather widely in some respects, they agree in general in emphasizing the primacy of mind in the universe; the immanence of God, usually thought of as being nonpersonal, though with definite personal qualities; a clear distinction between the historic Jesus and the Christ; the supremacy of good, if not always the unreality of evil; the essential goodness of human nature, man being thought of as divine; the possibility of healing through mental or spiritual means; and usually also the availability of abundance or prosperity to all men.

See Charles S. Braden, *Spirits in Rebellion: the Rise and Development of New Thought,* with extensive bibliography (1963).
(C. S. B.)

NEWTON, ALFRED (1829–1907), English zoologist, a specialist in the study of birds and one of the founders of the British Ornithologists' Union, was born at Geneva, Switz., on June 11, 1829. In 1854 he was elected to the Drury travelling fellowship of Magdalene college, Cambridge, and from then until 1863 he visited Lapland, Iceland, the West Indies, North America and Spitsbergen, studying chiefly ornithology. In 1866 he became the first professor of zoology and comparative anatomy at Cambridge, a position he retained till his death on June 7, 1907. His services to ornithology and zoogeography were recognized by the Royal society in 1900, when it awarded him a royal medal, having

elected him a fellow in 1870. He was also given the gold medal of the Linnaean society in 1900. He was editor of the ornithological journal *The Ibis* (1865–70) and *The Zoological Record* (1870–72). His books include *Zoology of Ancient Europe* (1862), *Ootheca Wolleyana* (1864–1902) and a *Dictionary of Birds* (1893–96), an amplification of the numerous articles on birds that he contributed to the ninth edition of the *Encyclopædia Britannica*.

NEWTON, SIR CHARLES THOMAS (1816–1894), British archaeologist, recognized for his discoveries in Asia Minor and as exponent of the systematic study of classical antiquities, was born at Bredwardine, Herefordshire, on Sept. 16, 1816, and educated at Shrewsbury school and Christ Church, Oxford. He entered the British museum as an assistant in the department of antiquities in 1840. He left it in 1852 to become vice-consul at Mytilene (on the island of Lesbos) with the object of conducting an archaeological reconnaissance of the islands and coasts of Asia Minor. Encouraged by financial assistance from Lord Stratford de Redcliffe, at that time British ambassador in Constantinople, Newton made notable discoveries of inscriptions on the island of Calymnos, off the coast of ancient Caria (*q.v.*). In 1856–57 he identified the remains of the mausoleum of Halicarnassus, one of the seven wonders of the ancient world. At Branchidae he discovered the statues that in ancient times had lined a sacred way, and at Cnidus, R. P. Pullan, working under Newton's direction, found a colossal lion now in the British museum. Together they published *A History of the Discoveries at Halicarnassus, Cnidus and Branchidae*, two volumes (1862–63).

Newton was the first (1862) to hold the position of keeper of Greek and Roman antiquities in the British museum. He secured considerable new material for the department. First Yates professor of classical archaeology in University college, London, from 1880 to 1888, he did much to promote Hellenic studies in Britain. Created knight commander of the Bath in 1887, Newton died at Margate, Kent, on Nov. 28, 1894.

See also CNIDUS. (J. M. WI.)

NEWTON, SIR ISAAC (1642–1727), English physical scientist and mathematician, one of the greatest figures in the entire history of science, was born at Woolsthorpe, near Grantham in Lincolnshire, on Dec. 25, 1642. His father had died the previous October. In 1645 Newton's mother remarried, moved to her new husband's home and left her son in the care of her mother. Newton was an indifferent scholar until a successful fight with another boy seems to have stimulated him and he became the best student of the school.

When Newton was 14 years old (1656), his mother became widowed for the second time, returned to Woolsthorpe and brought the boy home from school to run the farm. He proved to be an absentminded farmer, occupying himself with mathematics instead of attending to his work. His uncle, William Ayscough, rector of Burton Coggles, was a member of Trinity college, Cambridge, and in 1660 by his advice Newton was sent back to school to prepare for Cambridge. On June 5, 1661, he matriculated as a subsizar at Trinity college. Three years later he was elected as scholar and in Jan. 1665 took the B.A. degree. In 1667 he was elected a fellow of the college. In the autumn of 1665 the spread of the Great Plague caused the closing of the university. Until its reopening in the spring of 1667 Newton remained at Woolsthorpe. During those 18 months he laid the foundations for his famous discoveries in mathematics and physical science.

Early Basic Discoveries.—During the first of these months at Woolsthorpe, Newton developed what is now called the binomial theorem (*see* BINOMIAL THEOREM), and soon thereafter the method of fluxions, an early form of the differential calculus, the most important single mathematical innovation made since the time of the ancient Greeks. In May of 1666 he related, "I had entrance into the inverse method of fluxions," or the principle of the integral calculus, the method of calculating areas under curves and the volumes of solid figures.

These advancements alone would have entitled him to one of the highest places in the history of the sciences. But they were accompanied by two others, each of unusual significance. One was an analysis by experiment of the composition of white light and the nature of colours. The other was the discovery of the gravitational force holding the moon in its orbit, though nothing of this was published for almost 20 years (see *Work on Gravitation and Astronomy*, below). Newton later said that during those two years, "I was in the prime of my age for invention, and minded Mathematics and Philosophy [*i.e.*, science] more than at any time since."

Newton returned to Cambridge and to Trinity college in 1667, but did not publish his discoveries. Yet his teacher, Isaac Barrow—a man who distinguished himself in the fields of optics, mathematics and theology—recognized the superiority of his gifted pupil and resigned his chair, the Lucasian professorship of mathematics, so that Newton, at the age of 26, might succeed him. In a book on optics published in that year, Barrow recorded his indebtedness to Newton, calling him a "man of quite exceptional ability."

Work on the Telescope and Optics.—At this time the subject of optics was Newton's chief scientific interest. He worked at the problem of grinding lenses with nonspherical surfaces and continued to experiment with prisms. One result of his research was a new type of telescope, called the reflecting telescope because its principal light-gathering component was a mirror rather than the lens system of the refracting telescope. News of this invention came to the Royal society of London. Newton constructed a telescope and sent it to the society, to which he was elected a fellow. A week later, he suggested that he would like to present an account of the scientific discovery that had led him to design the new instrument, a discovery, in his words, "being in my judgment the oddest, if not the most considerable detection, which has hitherto been made in the operations of nature."

The main points of Newton's discovery were these. He found that if a narrow beam of white light, *e.g.*, sunlight, is allowed to pass through a slit into a prism, it will be dispersed into light of many colours covering the visual spectrum. He separated any narrow sector from that spectrum, as by placing a board with a slit in the path of the light leaving the prism, and allowed the monochromatic light to pass through a second prism. The result was that that beam bent but its hue was unchanged. Hence, those were wrong who had argued that the production of a spectrum by a prism arose from a "staining" action of the prism. Rather, as Newton's experiments showed, all light is bent or refracted as it goes from one medium to another (save in a direction perpendicular to the interface between two such media). Newton showed that white light is a mixture of light of all colours and that the prism separated the mixture into its component parts because the light of each colour is refracted by the prism at a different angle. But if light of a single colour were to be separated out in the spectrum, its colour would not change as it passed through another prism since it would not be a mixture but would be (to use Newton's own phrase) "homogeneal."

Knowing that white light is a mixture of light of all colours, and the prism separates light into these component colours, Newton could then explain many colour phenomena. For instance, a piece of white paper when illuminated with light of a single colour (say, red, green or yellow) will no longer appear to be white (but rather red, green or yellow). The colours of objects thus are related to the light by which they are seen, because "natural bodies . . . are variously qualified to reflect one sort of light in greater plenty than another." On this research are founded the science of colour and the technique of spectrum analysis.

In one set of experiments Newton studied the phenomenon known now as chromatic aberration. Since the prism experiments had shown that each colour has its own index of refraction, Newton concluded that the image of a body illuminated by white light (as sunlight) will not be sharp, there being a different focus for each colour. Thus an ordinary biconvex lens forms an image with an edge coloured like a miniature rainbow. Newton concluded erroneously from experiments that no one could ever make a lens system free of these colour fringes—free of chromatic aberration. He claimed to have shown by experiment that there is such a relation between the bending of light and dispersion into colours that no system of lenses could ever give an image without these effects.

In this he was mistaken; prisms and lenses can be made of different kinds of glass in pairs so that there is no dispersion although there is a net deviation or bending of light rays from their original paths. (*See* TELESCOPE.)

In order to prevent chromatic aberration from spoiling the quality of the telescopic image, Newton devised a telescope in which the principle element was a concave or magnifying mirror. Yet, as Christiaan Huygens pointed out, the full potentialities of Newton's reflecting telescope could not be realized until there was a method of grinding parabolic mirrors. (The most powerful telescopes at Mount Wilson and Palomar observatories are reflecting telescopes.) The telescope Newton made for the Royal society, one of their most prized possessions, is nine inches long and has a two-inch mirror.

When Newton sent his paper on light and colours to the Royal society, a committee was appointed to study the question further. One committee member, Robert Hooke, the originator of a theory of light and colour of considerable merit, had written a book, the *Micrographia* (1665), dealing in part with the same type of phenomena Newton had studied. Hooke admitted the accuracy of Newton's experiments, but doubted Newton's conclusions. Huygens also held to his own theory of colour, and as E. N. da Costa Andrade has explained, "he failed to understand . . . that Newton was not arguing about the nature of colour, about matters of doctrine, but describing experiments to show how white light and coloured light behaved, to show what were the measurable properties." Other critics arose; some misunderstood the experiments, but for the most part they disagreed on Newton's theory. Three of Newton's comments explain his position clearly: ". . . the Theory, which I propounded, was evinced by me, not inferring 'tis thus because not otherwise, that is, not by deducing it only from a confutation of contrary suppositions, but by deriving it from Experiments concluding positively and directly." "For the best and safest method of philosophising seems to be, first to enquire diligently into the properties of things, and of establishing these properties by experiment, and then to proceed more slowly to hypotheses for the explanation of them." As to "certain properties of light, which, now discovered, I think easy to be proved, . . . which if I had not considered them as true, I would rather have them rejected as vain and empty speculation, than acknowledged even as an hypothesis."

Discussions about Newton's paper were still going on in 1675. In December of that year he wrote, "I was so persecuted with discussions arising out of my theory of light that I blamed my own imprudence for parting with so substantial a blessing as my quiet to run after a shadow."

One effect of the controversy was that Newton was led to investigate other effects of colour, to inquire how light was produced and to develop the emission or corpuscular theory of light, according to which light is the product of emission by a luminous body of a host of tiny particles traveling in empty space with a speed of about 186,000 mi. per second; the laws of reflection and refraction were developed on mechanical principles, aided only by a supplementary hypothesis as to how, when falling on a transparent surface, some of the particles are reflected—bent back into the medium from which they have come—and others are refracted, along a new path inclined to the old, into the medium toward which they are traveling. It is in verification of this theory that light travels more slowly in a dense medium such as glass than in air. The theory was also applied to explain the colours seen when light is reflected from a thin film, a soap film or the thin layer of air between a convex lens of large radius and a flat reflecting surface on which it rests; in this case, when viewed in reflected light of a definite colour a series of dark and light rings circling round a central black spot is seen. Newton determined the law connecting the radius of a bright ring and the colour of the light. Since the radius depends on the colour, the bright rings for the various colours, when white light is used, will be different and the observer will see a series of coloured rings surrounding the black central spot. This phenomenon is now known as Newton's rings. (*See* LIGHT: *The Age of Newton and Huygens.*)

Hooke was again a critic; in his *Micrographia* he had adopted a kind of wave theory of light, according to which light consists of a series of pulses transmitted through a medium pervading space, the universal ether, and had endeavoured to explain rectilinear propagation, reflection and refraction as well as dispersion and the colours of thin plates. Newton, in his explanation of optical phenomena indicated that corpuscles of light might be guided by waves in an ethereal medium; yet he thought little of Hooke's attempts at explanation. From the work of Thomas Young in 1804 and the brilliant work of the French genius Augustin Fresnel a few years later came description in terms of wave theory covering the phenomena of light as then observed. Young drew on Newton's concepts of waves as well as on the views of Christian Huygens.

Newton rejected a simple wave theory of light because it could not account for rectilinear propagation or for polarization. As Newton demonstrated, all wave phenomena—for instance, sound—carry the disturbance into the region of shadow, or around obstacles. It never occurred to him that the waves of light might be exceedingly small. Yet in studying the colours of thin plates, Newton provided much of the necessary information for the later wave theorists. Thomas Young showed that Newton's careful measurements led to an accurate determination of the wavelength of the several colours. In his early papers, and later on in his *Opticks* (first edition 1704) Newton advanced an explanation of optical phenomena that was neither a pure corpuscular theory nor a pure wave theory. According to Newton it seemed probable that light consists of a series of corpuscles emanating from luminous bodies. These corpuscles give rise to waves as they travel through the ether and many optical phenomena (such as the colours of thin plates) arise from the properties of both waves and corpuscles. This explanation fell from favour during the 19th century, when the wave theory of light was fashionably accepted. But since A. Einstein wrote of photons of 1905, many writers have called attention to a similarity between Newton's views and those of the 20th century, in which there is a fusion of elements of both wave and corpuscular theories of light.

Work on Gravitation and Astronomy.—Since the early years at Woolsthorpe, Newton had been considering the main problem of motion: what force is it that keeps the planets moving about the sun in the Copernican system? Newton proposed that one and the same force of universal gravitation causes the planets to revolve about the sun in elliptical paths according to Kepler's laws. Furthermore, this force, which loses effect with the square of the distance, keeps the moon in motion about the earth and causes objects to fall to earth.

Newton related that the occasion of this discovery was the fall of an apple. What did he mean? If the moon moves in an orbit around the earth, and does not fly off in a straight line along a tangent to the orbit, there must be a force directed to the earth, a centripetal force pulling the moon to the centre of the earth. The situation is similar to that of a ball whirling in a circle at the end of a string; if the string breaks, the centripetal force ceases to be exerted, and the ball flies off along a tangent. Expressed differently, the moon is continually drawn away from its rectilinear tangential path by a force; this force causes the moon to fall continually away from a straight line and to follow its observed orbit. Newton computed the distance the moon must fall in each second. If the force that makes the moon fall varies inversely as the square of the distance, then, since the moon is at a distance of 60 earth radii from the earth's centre, the earth's force on the moon is $\frac{1}{60\times 60}$, or $\frac{1}{3,600}$ of what it would be if the moon were at the earth's surface. Hence, assuming that the force of gravity keeps the moon in its orbit and that this force varies inversely as the distance, Newton could predict the rate of fall of an object to the earth. This proved to be approximately what is observed: as Newton expressed it, the observation agreed "pretty nearly" with the theory. He also was able to show that Kepler's laws implied a central force that varied inversely as the square of the distance. Conversely, by assuming a single force exerted between sun and planets proportional to the masses of the sun and the planet involved and inversely proportional to the

square of the distance between them, one could derive Kepler's laws and show that one and the same force acted between the planets and the sun, between any planet and its satellite, between the oceans and sun and moon (so as to produce the tides) and, in general, between any two bits of matter in the universe.

In London there were great debates about planetary motions and about the orbits that would result from specified types of forces. Discussions went on at the Royal society or in the houses of the members—Sir Christopher Wren, Hooke, Edmund Halley and others who were active in the society—until one Wednesday in Jan. 1684 Halley met Wren and Hooke and the latter declared "that he had demonstrated all the laws of the celestial motions." Halley confessed his ignorance and Sir Christopher "to encourage enquiry said he would give Hooke or me"—the quotation is from a letter of Halley to Newton—"two months to bring him a convincing demonstration." Sir Christopher offered to give "a book of 40 shillings" to the one who first found the solution. So it remained until August, when Halley visited Newton at Cambridge and questioned him concerning the trajectory of a body moving under the action of a central force which varied as the inverse square of the distance from the centre. Halley wrote that Newton knew the answer and "had brought this demonstration to perfection." Newton promised to look for the old proof but could not find it, "and not finding it did it again." Halley returned to Cambridge and persuaded Newton to put his work in form for the Royal society. On Dec. 10, 1684, Halley informed the society that he had lately seen Newton, who had showed him a curious treatise, *De Motu*, which, upon Halley's desire, was sent to the society to be entered on their register.

Newton then attacked and solved a major problem. Hitherto his calculations had proceeded on the assumption that the sun and the planets could each be treated as though they were points, with all their matter concentrated at their respective centres. But was this true or was it merely an approximation resulting from the fact that the planetary distances were so immense that even a great sphere like the sun could in comparison be treated as a point?

Newton proceeded to work this out, on the assumption that each particle of the sun attracted an external particle with a force proportional to the product of the masses of the two and inversely proportional to the square of the distance between them. Thus he showed that if the sun were of uniform density the resultant force on the external particle would be the same as that which would be exerted if the whole mass of the sun were concentrated at the centre (*see* MECHANICS).

Some scholars have held that it was the difficulty of solving this problem that had caused Newton in 1665 to lay aside his astronomical calculations. Others agree with H. Pemberton's remark that a crude value for the earth's radius was responsible for the delay. In any event, the calculations were resumed with a more precise knowledge of the moon's distance.

The writing of the *Principia* was begun in March 1686. Entitled *Philosophiae Naturalis Principia Mathematica*, or "Mathematical Principles of Natural Philosophy," the work was first published in the summer of 1687. At that time the Royal society was in difficulties as to funds and Halley took the whole cost on himself. Hooke, when the book was first presented, claimed that he had anticipated Newton in part of it, and in the correspondence that followed Halley did all he could to smooth over the difficulties and persuade Newton to continue his work.

The *Principia* set the seal to Newton's reputation. It explained for the first time the way in which a single mathematical law could account for phenomena of the heavens, the tides and the motion of objects on the earth. The whole development of modern science begins with this great book. For more than 200 years it reigned supreme; popular theories of cosmology were based on the principles laid down by Newton. His mechanics guided astronomers and men of science in their search for natural knowledge.

Religious Beliefs.—Newton was profoundly interested in religious matters. He studied carefully the writings of the Church Fathers, the early writers on Christianity, and sought evidence to bolster his own principles of faith, which were anti-Trinitarian. John Maynard Keynes, who studied Newton's writings on esoteric and theological matters, concluded that Newton was "a Judaic monotheist of the school of Maimonides." Very likely this was the reason that Newton refused Holy Orders and had to be given a special dispensation to hold his professorship. He kept his religious convictions, like his experiments on alchemy, secret. Ultimately, the amount of time and energy that he devoted to alchemy probably rivaled that given to physics or to mathematics. So well did Newton keep his secret that his activities in these two realms are not generally and fully known.

Middle and Later Life.—In 1687 James II tried to force the university to admit as a master of arts Father Alban Francis, a Benedictine monk, without taking the oaths of allegiance and supremacy. Newton was one of those who led the resistance to the royal action, and appeared before Lord Jeffreys to argue the case for Cambridge. In the end the deputies were reprimanded and John Peachell, the vice-chancellor, was deprived of his office. Newton's share in the affair led to his being elected member of parliament for the university in 1689, retaining the seat till the dissolution next year. He was elected again in 1701, but he never took any prominent part in politics.

Upon the dissolution of parliament in 1690 he returned to Cambridge and continued for a time his mathematical work; this was interrupted in 1692–94 by a serious illness. He was suffering from insomnia and nervous trouble. There was a report that he was going out of his mind. In June 1694 Huygens wrote to G. W. Leibniz, "I do not know if you are acquainted with the accident to the good Mr. Newton, namely, that he has had an attack of phrenitis which lasted eighteen months and of which they say his friends have cured him by means of remedies and keeping him shut up." For some time his friends had been anxious to obtain some recognition of his work; this came in 1695. Charles Montague, later earl of Halifax, a former fellow of Trinity who was chancellor of the exchequer, offered him the post of warden of the mint. This he accepted and four years later became master. In the same year he was elected one of the eight foreign associates of the French Academy of Science.

In 1696 John Bernoulli addressed a letter to the mathematicians of Europe, challenging them to solve two problems and giving six months for the solution. On Jan. 26, 1697, Newton received from France two copies of the printed paper containing the problems and the following day sent the solutions to the Royal society. They were transmitted anonymously to Bernoulli, who, as he said, recognized the lion by his talon, *"tanquam ex ungue leonem."*

As warden of the mint Newton had retained his Cambridge offices, but soon after his appointment as master he named a deputy, and in 1701 resigned his professorship and the fellowship at Trinity. He had moved to London, where he continued his duties as master with marked efficiency until his death in 1727. In 1703 Newton became president of the Royal society and was re-elected annually until his death. Queen Anne visited Cambridge in 1705 and on this occasion Newton was knighted. About the same time the controversy with Leibniz as to the invention of the differential calculus began. It is now generally recognized that Leibniz invented the calculus independently of Newton and that Newton's claim that Leibniz was a plagiarist had no foundation. Early in 1727 Newton was taken seriously ill; he died on March 20, 1727, and was buried in Westminster abbey on March 28.

Published Works.—Since the first issue of the *Principia* in 1687 (*see* above), there have been many editions. In 1709 Newton consented to have Roger Cotes, a fellow of Trinity, help him prepare a second edition, which was published in 1713; a third edition made with the aid of Henry Pemberton appeared in 1726. This third Latin edition was reprinted in Geneva in 1739–42 with an excellent commentary by two friars, Le Sueur and Jacquier; often reprinted, this is known incorrectly as the Jesuits' edition. An English translation first published by A. Motte as *Mathematical Principles of Natural Philosophy* (1729) was revised and republished (1803), revised again by Florian Cajori and reprinted together with Newton's *System of the World* (1934).

The *Opticks*, first published in 1704, went through three editions in Newton's lifetime; a modern edition appeared in 1952.

The scientific papers published by Newton in his lifetime are collected in *Isaac Newton's Papers and Letters on Natural Philosophy*, edited by I. Bernard Cohen (1958). The most recent edition of Newton's writings, edited by S. Horsley in five volumes under the title *Opera quae extant omnia* (1779–85), is not complete.

Correspondence of Scientific Men of the 17th Century, etc., From the Originals in the Collection of the Earl of Macclesfield, edited by S. P. Rigaud (1841), and *Correspondence of Sir Isaac Newton and Professor Cotes, Including Letters of Other Eminent Men* (1850), edited by J. Edleston, contain many of Newton's letters, and the latter volume contains a synopsis of his life. A selection of Newton's writings on religion is contained in H. McLachlan (ed.), *Theological Manuscripts* (1950); earlier published religious writings were *Chronology of Ancient Kingdoms Amended* (1728), and the *Apocalypse of St. John* (1733).

The Royal society has undertaken an edition of *The Correspondence of Isaac Newton*, of which the first three volumes (1959–61), were edited by H. W. Turnbull and J. F. Scott.

For information on the impact of Newton's work on scientific thought, *see* SCIENCE, HISTORY OF: *Determinism and Postdeterminism*. For further information on his major scientific contributions, *see* CALCULUS, DIFFERENTIAL AND INTEGRAL; CELESTIAL MECHANICS; GRAVITATION; MOTION, PRINCIPLES AND LAWS OF. *See* also references under "Newton, Sir Isaac" in the Index.

BIBLIOGRAPHY.—G. J. Gray, *Bibliography of the Works of Sir Isaac Newton*, 2nd ed. (1908); *A Descriptive Catalogue of the Grace K. Babson Collection of the Works of Sir Isaac Newton*, Babson Institute (1950), with *Supplement* (1955); A. R. Hall and M. B. Hall (eds.), *The Unpublished Scientific Papers of Sir Isaac Newton* (1962).

L. T. More, *Isaac Newton* (1934). The most readable account of Newton's life and achievement is E. N. da Costa Andrade, *Sir Isaac Newton* (1954); still useful for the amount of quoted material is *Memoirs of the Life, Writings, and Discoveries of Sir Isaac Newton*, by Sir David Brewster, 2 vol. (1855; reprinted 1860). Valuable critical commentaries are to be found in Augustus de Morgan, *Essays on the Life and Work of Newton*, edited with notes and appendices by P. E. Jourdain (1914). A brief account of Newton's life and works is given in S. Brodetsky, *Sir Isaac Newton* (1928). Of great value to students of Newton is the *Catalogue of the Portsmouth Collection of Books and Papers Written by or Belonging to Sir Isaac Newton* (1888), which describes the great mass of Newton's papers which came at his death into the hands of Conduitt. Among general commentaries may be mentioned: H. Pemberton, *A View of Sir Isaac Newton's Philosophy* (1728); Colin Maclaurin, *An Account of Sir Isaac Newton's Philosophical Discoveries* (1748); F. Rosenberger, *Isaac Newton and seine Physikalische Principien* (1895); Léon Bloch, *La Philosophie de Newton* (1908); I. Bernard Cohen, *Franklin and Newton* (1956).

Of great importance for the controversy with Leibniz is the report drawn up by order of the Royal Society, published under the title *Commercium Epistolicum* (1712), of which editions appeared in 1722 and 1725. *See* also S. P. Rigaud, *Historical Essay on the First Publication of Sir I. Newton's Principia* (1838); W. W. R. Ball, *Essay on Newton's Principia* (1893); J. W. L. Glaisher, *Bi-Centenary of Newton's Principia* (1888); *Isaac Newton, 1642–1727*, ed. by W. J. Greenstreet, a memorial volume (1927); History of Science Society, *Sir Isaac Newton, 1727–1927* (1928); W. Stukeley, *Memoirs of Sir Isaac Newton's Life, 1752* (1936); H. W. Turnbull, *Mathematical Discoveries of Newton* (1945); Royal Society of London, *Newton Tercentenary Celebrations, 15–19 July, 1946* (1947). (R. T. GL.; I. B. C.)

NEWTON, JOHN (1725–1807), one of the leaders of the Evangelical revival and friend of the poet William Cowper (*q.v.*), was born in London on July 24, 1725. He had little formal education and served from 1736 to 1742 on the ship in the Mediterranean trade of which his father was master. Early in 1744 he was impressed on board a man-of-war, the "Harwich," where he was made midshipman. For an attempt to escape while his ship lay off Plymouth he was publicly flogged and degraded. After this experience he joined another vessel bound for Africa, where he took service under a slave dealer. Then in 1747 he returned to the sea, and for a time became captain of a slave ship. Newton, known previously for his unbelief and blasphemy, underwent conversion during a storm at sea in 1748. He finally gave up seafaring in 1755 and was appointed tide surveyor at Liverpool where he came to know George Whitefield and John Wesley. He now began to study Greek and Hebrew and in 1758 applied to the archbishop of York for ordination. This was refused him, but having been offered the curacy of Olney, Buckinghamshire, in April 1764 he was ordained by the bishop of Lincoln. In Oct. 1767 William Cowper settled in the parish. The two men became close friends and they published together the *Olney Hymns* (1779). Newton's contribution included, among many other hymns, the well-known "How Sweet the Name of Jesus Sounds!" and "Glorious Things of Thee are Spoken." The most important of his works was *Cardiphonia, or the Utterance of the Heart* (1781), a series of devotional letters. It was through his letter writing that Newton made his greatest contribution to the Evangelical movement. In 1779 he left Olney to become rector of St. Mary Woolnoth, London. There he exercised an important ministry, influencing many, among them William Wilberforce, the future leader in the campaign for the abolition of slavery. Like Cowper, Newton held Calvinistic views, although his evangelical fervour allied him closely with the sentiments of Wesley and the Methodists. He died in London on Dec. 21, 1807.

Loane, *Oxford and the Evangelical Succession* (1950); J. H. Johansen, "The Olney Hymns," *Papers of the Hymn Society of America*, vol. xx (1956). (G. Hu.)

NEWTON, JOHN (1823–1895), U.S. army officer and engineer, was born in Norfolk, Va., on Aug. 24, 1823, and graduated from the U.S. Military academy at West Point, N.Y., in 1842. From 1842 to 1861 he was engaged in the construction of coast defense works and in improving waterways. He was assistant professor of engineering at the U.S. Military academy from 1843 to 1846, became a captain in 1856 and was chief engineer in the Utah expedition of 1857–58. He served in the Virginia campaign of 1861 at the start of the American Civil War. He distinguished himself in the Seven Days' battle and at Antietam and after the battle of Fredericksburg was made major general, U.S. volunteers. In the Chancellorsville campaign Newton took part in the storming of Marye's heights at Fredericksburg, on May 3, 1863, and at the battle of Gettysburg he was for a time in command of the I corps. Later he took part in the Atlanta campaign as a division commander in Gen. W. T. Sherman's army. For gallant conduct at Peachtree creek he was made brevet brigadier general, and at the close of the war was made brevet major general, U.S. army. In 1884 he became chief of engineers, and held this position until his retirement in 1886. One of his notable engineering achievements was the successful blasting of an obstruction in New York harbour in 1885 with 250,000 lb. of dynamite. In 1887–88 he was commissioner of public works in New York, and from 1888 until his death on May 1, 1895, was president of the Panama Railroad company.

NEWTON, a suburban, residential city of Middlesex county in eastern Massachusetts, U.S., is located on the south bank of the Charles river, immediately west of Boston (*q.v.*) and Brookline. Settled in 1639 as part of Cambridge, it was separated in 1688 and incorporated as New Towne, changing its name to Newton in 1691. During the 19th century farming was the principal occupation although the upper and lower falls areas of the Charles were busy industrial centres. Newton's growth as a residential suburb was given impetus by the opening of the Boston and Worcester railroad in 1834. Newton was incorporated as a city in 1873.

With a population (1960) of 92,384, Newton is part of the Boston standard metropolitan statistical area. Despite its size Newton has kept the flavour of a small suburban town, being divided into 14 individual villages, and containing a number of parks, playgrounds and other recreational facilities. Industries, limited by zoning laws, manufacture electronic tubes, electric signalling systems, textiles, rubber goods and plastics. Situated within the city are Newton Junior college (1946); Boston college (Roman Catholic, 1863); Newton College of the Sacred Heart (Roman Catholic, 1946); and the Andover-Newton Theological school formed by a merger of Andover Theological seminary (Congregational, 1808) and Newton Theological institute (Baptist, 1825). (M. R. F.-S.)

NEWTON ABBOT, a market town in the Totnes parliamentary division of Devon, Eng., 16 mi. S.S.W. of Exeter by road and near the head of the Teign estuary. Pop. (1961) 18,060.

has a Wednesday cattle and general market; it is also a shopping centre and railway junction with various light industries. The two parish churches, St. Mary's in Wolborough and All Saints' in Highweek, are Perpendicular in style. The Jacobean Forde house (1610) was visited by Charles I and William of Orange, who first read his declaration to the people of England at Newton Abbot market cross. The 15th-century Bradley manor belongs to the National trust. The portion of Newton Abbot in the parish of Highweek was formerly a separate town known as Newton Bushel. There is a racecourse on the opposite bank of the Teign. Newton Abbot rural district council (area 144.8 sq.mi.; pop. [1961] 25,963) embraces 22 parishes and extends from Dartmeet (central Dartmoor) on the west to Dawlish and Teignmouth urban districts on the east.

NEWTOWNABBEY, an urban district of County Antrim, N.Ire., lies on the shores of Belfast lough, adjoining the northern boundary of the city and county borough of Belfast. Pop. (1961) 37,440. The third largest town in Northern Ireland, it was constituted by private act of parliament in 1958, when seven former village communities were amalgamated to form the new urban district, which includes a civic centre and about 160 ac. of municipal playing fields and public parks. The basic textile industries have been supplemented by the establishment of two central government factory estates. (A. R. Ma.)

NEWTOWNARDS, a municipal borough of County Down, N.Ire., lies at the northern end of Strangford lough, 10 mi. E. of Belfast by road. Pop. (1961) 13,090. The town was founded by Sir Hugh Montgomery in 1608, at the site of a Dominican friary founded in 1244 by Walter de Burgh (ruins of which survive), and was incorporated in 1613. It is heavily industrialized, and as well as the spinning and weaving of linen its industries include the manufacture of hosiery, aircraft components, sheet-metal work and draftmen's instruments, fabric printing and rayon weaving.

Immediately to the northeast of the town is Movilla (Magh Bhile) with remains of a 6th-century abbey church attributed to St. Finian. (Hu. S.)

NEW TOWNS. In order to decentralize population and industry from London and other big towns in Great Britain, a New Towns act was passed in 1946. Following this, 12 New Towns were designated in England and Wales and 3 in Scotland, each with its own development corporation financed by the government. Relatively undeveloped sites were usually chosen and the New Towns were to be self-contained and locally governed. Each was to have an admixture of population so as to give it a balanced social life. Final population figures ranged from about 30,000 to 80,000 or more in England and Wales (70,000 in Scotland). The 12 New Towns designated in England and Wales were Aycliffe and Peterlee in County Durham, Bracknell in Berkshire, Corby in Northamptonshire, Crawley in Sussex, Cwmbran in Monmouthshire, Basildon and Harlow in Essex, and Hatfield, Hemel Hempstead, Stevenage and Welwyn Garden City in Hertfordshire. The three Scottish ones were Glenrothes in Fife, East Kilbride in Lanarkshire and Cumbernauld in Dunbartonshire.

By the early 1960s half a million people lived in the 15 New Towns but pressure on the big cities remained acute. Accordingly additional New Towns were designated at Skelmersdale in Lancashire, Livingston partly in West Lothian and partly in Midlothian, Dawley in Shropshire, Redditch in Worcestershire, Runcorn in Cheshire, Washington in Durham and Risley, near Manchester.

The New Towns act, 1959, provided for the establishment of a New Towns commission which was to take over the assets and properties of the New Towns as each was substantially completed. Early in 1962 Crawley and Hemel Hempstead were handed over to the commission.

See HOUSING: *Great Britain: Town Planning after World War II.*

See also F. J. Osborn and A. Whittick, *New Towns: the Answer to Megalopolis* (1963), which contains a full bibliography.

NEWTOWN ST. BOSWELLS, a village of Roxburghshire, Scot., lies 40 mi. S.E. of Edinburgh by road, on the main Edinburgh-Carlisle railway and main Edinburgh-Newcastle road. Pop. (1961) 1,050. Until 1929 the village was mainly populated by employees of the old North British Railway company, for it was an important railway junction; by the mid-1960s, however, all branch lines had been closed. The county buildings were erected there in 1929 and it is now an important administrative centre with the offices of the Edinburgh and East of Scotland College of Agriculture and a branch of the department of agriculture for Scotland. A livestock market holds weekly sales.

Dryburgh abbey (1¼ mi. E.), founded in 1150 for Premonstratensians by Hugh de Morville and financed by David I, is one of the prime attractions of the border country. Sir Walter Scott and Field Marshal Earl Haig of Bemersyde and members of their families are buried there.

St. Boswells, a residential village, lies 1 mi. E.S.E. of Newtown St. Boswells. (J. R. Fr.)

NEW WESTMINSTER, a city of British Columbia, Can., located on the estuary of the Fraser river, 15 mi. from its mouth, on the steep north bank at a bridging point of the Trans-Canada highway and the Canadian National and Great Northern railways. Pop. (1961) 33,654. The city is an integral part of metropolitan Vancouver. It is a freshwater port with berthing and cargo handling facilities for deep-sea ships which load timber, lead, zinc, fertilizer, apples and grain. Gov. James Douglas incorporated the city in 1860 and until 1866 it was the capital of the mainland colony of British Columbia. It is a trading and manufacturing centre with one of the largest concentrations of the forest products industry in the province. The processing of lumber, Fraser river salmon and fruit and vegetables from the adjacent farming district are among the principal manufacturing industries. (G. A. W.)

NEW WINDSOR, often called simply WINDSOR, a royal borough of Berkshire, Eng., stands on the south bank of the Thames opposite Eton, Buckinghamshire, 23 mi. W. of London by road. Pop. (1961) 27,126. Despite several references to it in Domesday Book, it is called New Windsor because further downstream lies Old Windsor, which was a royal manor in Saxon times.

The dominating feature of the town is Windsor castle, standing on a great outcrop of chalk. William the Conqueror built his fortress there but its only visible remains now are the mound where the Round tower stands. Great gray walls surround the castle, rising high above the Thames valley and also above Thames street which climbs steeply from Windsor bridge to High street, one of the highest parts of the town. On the way up, Curfew tower with its clock protrudes above the walls and dominates the approach. (*See* WINDSOR CASTLE.)

Farther along High street, passing Market Cross house, juts out the Guildhall, designed by Sir Thomas Fitz who superintended its erection from the laying of the foundation stone in 1687 till his death in 1689. Under the Guildhall, almost forming part of the street, is the old Corn market. The pillars—which only appear to support the Guildhall above, for they have never touched the beams—were erected by Sir Christopher Wren because, as tradition has it, members of the corporation feared the floor would collapse under their weight. It is said that Wren also supervised completion of the building. On its end walls statues of Queen Anne and her husband, Prince George of Denmark, face respectively toward the Thames and the Long walk. The Guildhall has a collection of paintings, including a portrait of Queen Elizabeth II, presented to the corporation by successive sovereigns; it also contains an exhibition of manuscripts, pictures, plans and objects showing the history of Windsor from early times to the present day. The council still meets in the Guildhall as do its committees, but the administrative offices of the corporation are now at Kipling Memorial building in Windsor.

The corporation is an ancient one which had its first known charter in 1277. Since then it has had other charters, the last one being dated 1685. Near the Guildhall is the parish church of St. John the Baptist where the corporation on civic occasions attends divine service. The church has, among other treasures, a painting of "The Last Supper," attributed to Franz Cleyn (d. 1658). Holy Trinity parish church has many regimental memo-

rials, for it is attended by the military units stationed at Windsor.

Primarily a residential town with many of its inhabitants working on the trading estate in nearby Slough or in London, New Windsor is served by both the western and southern regions of British railways.

The principal industries are light engineering, optical works, printing and the making of scientific instruments. The town is fortunate in being almost surrounded by Windsor Great park, a royal domain which contains the famous Long walk (of about 3 mi.) and stretches southward to Virginia water. Part of the Home park is also open to the public and there are playing fields and other open spaces. Windsor has a racecourse and an annual horse show. Pleasure boats ply up and down the river during the summer and great numbers of people visit the town.

Roman coins have been found at St. Leonard's hill, and Saxon remains at Old Windsor, the second largest town in Berkshire at the time of Domesday and excavated in the 1950s. For hundreds of years from Saxon times onward kings hunted in Windsor forest. On the Long walk Henry VIII listened to the sound of the gunfire announcing the execution of Anne Boleyn; Nell Gwyn lived there; George III raised Merino sheep in the park; and at Frogmore in the castle grounds Queen Victoria erected for the prince consort the mausoleum in which she also was later buried. (J. E. S.)

NEW YEAR'S DAY, the first day of the year. New Year's festivals, among the oldest and most universally observed, generally include rites and ceremonies expressive of mortification, purgation, invigoration and jubilation over life's renewal. The earliest-known record of a New Year's festival dates from about 2000 B.C. in Mesopotamia, where the year began with the new moon nearest the spring equinox (mid-March; Babylonia) or nearest the autumnal equinox (mid-September; Assyria). The year began for the Egyptians, Phoenicians and Persians with the autumnal equinox (Sept. 21) and for the Greeks, until the 5th century B.C., with the winter solstice (Dec. 21). By the Roman republican calendar the year began on March 1; after 153 B.C. the official date was Jan. 1, and this was confirmed by the Julian calendar (46 B.C.).

For the Jewish religious calendar the year begins with the first day of the month of Tishri (Sept. 6–Oct. 5; *see* JEWISH HOLIDAYS: *Rosh Hashana*). In early medieval times most of Christian Europe regarded March 25 as the beginning of the year, though for Anglo-Saxon England New Year's day was Dec. 25. William the Conqueror decreed that the year start on Jan. 1, but later England began its year with the rest of Christendom on March 25. Jan. 1 was restored as New Year's day by the Gregorian calendar (1582), immediately adopted by Roman Catholic countries. Other European countries followed suit: Scotland, 1660; Germany and Denmark, about 1700; Russia, 1706; England, 1752; and Sweden, 1753.

NEW YORK, one of the original 13 states of the United States, ranks 30th in area among the states, but first in population, trade and manufacturing. Its land area is 47,939 sq.mi. and the area of inland waters is 1,637 sq.mi. The state has a triangular outline, with a breadth from east to west of 322 mi. and from north to south, on the line of the Hudson river, of 312 mi. In addition, Long Island thrusts about 118 mi. eastward from New York bay.

New York is bounded on the north by Lake Ontario, the St. Lawrence river and Canada; on the east by Vermont, Massachusetts and Connecticut; on the south by the Atlantic ocean, New Jersey and Pennsylvania; and on the west by Pennsylvania, Lake Erie and the Niagara river.

Because of its great wealth and the concentration of business and industry, New York has come to be known as the "Empire state." The state capital is Albany and the state ratified the federal constitution on July 26, 1788, the 11th of the colonies to do so. The sugar maple has been adopted as the state's official tree and the rose as the official flower. The state flag has a blue field upon which is imprinted the state coat of arms with the motto "Excelsior" inscribed on a white ribbon beneath it.

PHYSICAL GEOGRAPHY

Physical Features.—The most notable topographical feature of the state is the circular Adirondack mountain area in the northeast. This ancient mountain mass of Pre-Cambrian rocks resembles more the Laurentian mountains of Canada than the Appalachians. The highest peak is Mt. Marcy (5,344 ft.). Other peaks range from about 2,000 ft. to about 5,000 ft. Even the highest summits are worn and rounded and are largely forest covered. The Adirondack area proper, and much of the surrounding ring of younger sedimentary rocks is too rugged and the soil is too thin for agriculture. Because of the beautiful scenery, this is a favourite recreational centre. In summer, visitors hunt, fish, swim and climb; in winter, they skate and ski. Small factories have developed, partly to utilize the products of forest, mine and farm and partly to use the extensive water power.

South of the Mohawk river and west of the Hudson river rises a high level plateau which extends westward to the Pennsylvania border. There the sedimentary strata are essentially horizontal and of the Paleozoic age, mainly Devonian. This plateau area, which comprises more than half of the state, has much variety. The elevation decreases toward the north by means of a series of "steps," the lowest elevation being on the Ontario plain which skirts the southern shore of Lake Ontario for a width of about 35 mi. The fertile and level lands along the shores of Lake Ontario and Lake Erie have attracted many farmers especially fruit growers. The large lakes have a moderating effect on the climate and lengthen the growing season. The plateau surface becomes more rugged toward the south and the east. Elevations of about 1,500 and 2,000 ft. are common from Chautauqua lake to the Catskill mountains. The plateau is cut by many streams which have created deep valleys. The valley walls rise to undulating and often fairly level uplands which provide excellent pasturage for dairy cows. In southeastern New York, near the Appalachians the plateau becomes much higher, reaching its culmination in the Catskills. Summit elevations of from approximately 3,000 to 4,000 ft. are common, the highest point being Slide mountain (4,185 ft.). Like the Adirondacks, this region is largely forest covered and is famous as a site of summer and winter sports. The Helderberg mountains are really an escarpment facing the lower Mohawk and the Hudson rivers south of Albany, where there is a downward step in the plateau. The steeply rising face of the plateau is the result of the resistance of a durable layer of limestone, known as the Helderberg limestone. The most notable escarpment in western New York is the Niagara which extends eastward from Canada, forming the Niagara falls, and creating a sharp drop at Lockport.

South of the Catskills there are a number of different topographical features which are caused by the belts of differing rock structure that cross the state from southwest to northeast. The most pronounced of these upfolded strata form the low Shawangunk mountains, which descend to a lowland region of folded strata of limestone, slate and other rocks in Orange and Dutchess counties. This lowland area is a continuation of the great valley of the Appalachians and extends northeast into Vermont and southwest across New Jersey, Pennsylvania, Maryland and Virginia. It is bounded on its southeast side by the highlands, a belt of crystalline rocks which merge into the Taconic range, or Berkshires. The Hudson river has cut a deep gorge through the highlands. South of the highlands is a belt of Triassic sandstone which, because of its peculiar columnar jointing, has developed the famous Palisades of the lower Hudson. Long Island, a northeast extension of the coastal plain, has few heights of more than 200 ft. High hill, the highest point, is only 410 ft. above sea level.

The continental glacier covered the entire surface of New York with the exception of a very small area in the extreme western part. It broadened and deepened many of the valleys, rounded the hills, turned aside many streams, causing changes in drainage giving rise to innumerable waterfalls and rapids, and formed the

Bottom left: A dairy farm near Syracuse. Milk and dairy products provide more than half of the total annual farm income of New York state

Bottom right: Tanker passing through the Erie canal at Waterford, near the junction of the Champlain and Erie divisions of the New York State Barge canal system which is about 525 mi. long

thousands of lakes which dot the state. As the ice receded, it halted at various points where it formed moraines and other glacial deposits.

Drainage.—New York is drained by streams running in various directions. The St. Lawrence river system receives most of the runoff, mainly from short streams from the plateau and from the Adirondacks. A small part of the state, in the west, is drained toward the Ohio river. A much larger area drains into the Susquehanna river and into Chesapeake bay. A part of the Catskills, and the region farther south, drains into Delaware bay through the Delaware river. The Hudson is by far the most important river within the state, being navigable for 151 mi. from the sea. It is noted for its remarkable scenery, especially where it crosses the highlands.

There are about 8,000 small, glacial lakes and ponds in the state. The largest lake apart from Lakes Erie and Ontario is Lake Champlain into which Lake George drains. The largest lake entirely within the state is Oneida lake. In the central part of the state is a series of elongated lakes called the Finger Lakes; the six largest are Cayuga, Seneca, Keuka, Canandaigua, Owasco and Skaneateles. In the extreme western part of the state is Chautauqua lake. New York has many falls and rapids, the largest of which is the cataract of Niagara which is about 1 mi. wide and 167 ft. high. The U.S. fall is entirely within New York, but the Canadian boundary line passes down the centre of the Horseshoe or Canadian fall.

Climate.—New York has a wide variety of climate because of its topography and location between the Atlantic ocean and the Great Lakes. The average mean annual temperature in the state is about 45° F. (about 7° C.), though it varies from 52.3° F. in New York city to less than 40° F. in the Adirondacks. The mountain and plateau regions have heavy snowfalls and extreme changes in temperature. Daytime temperature is often high, but the nights are decidedly cool because of the rapid loss of heat. In contrast, Long Island has light snowfall and fairly constant temperature because of the moderating effect of the ocean. Similarly, the area adjoining the Great Lakes, and to a lesser extent the Finger Lakes, has long, mild autumns and winters much less severe than the uplands a few miles away.

There is a wide variation in the annual precipitation, though the greatest amount falls during the growing season. The average annual precipitation in New York city is 42.11 in.; in Syracuse 35.31 in.; in Binghamton 34.41 in. The average annual snowfall ranges from 31.3 in. in New York city to 87.0 in. in Oswego and 126.6 in. at Lake Placid. New York lies within the northeastern cloud belt and therefore receives less sunshine than the central or western states.

Soil.—The soil is mostly glacial drift, with the depth and composition often varying greatly even within small areas. The most widely distributed soil, especially in the eastern half of the state is clay formed by the glacial pulverizing of limestone and shale. The most fertile soil is found along the shores of the lakes and in the river valleys where alluvium has accumulated.

Plants and Animals.—A dense forest covered the state during the colonial period except for a few natural clearings in the Genesee valley but only in the recesses of the Adirondacks are there tracts of the original forest. There are 149 kinds of trees, of which 116 are native. Spruce, pine and hemlock are the commonest trees in the Adirondack and Catskill mountains. The evergreens provide a rich background for the maples, birches and beeches. Oak, short-leaf pine, maple, hickory and gum trees are the principal ones on Long Island. Oak, hickory, chestnut and elm are the most predominant trees in the Hudson–Mohawk valley, the Lake Ontario plain and the deeper valleys of the plateau.

New York also has thousands of varieties of plants and ferns. In the forests there are wild sarsaparilla, Solomon's-seal, trillium and many other kinds of wild flowers. Buttercups, clover, violets, wild roses and rushes are common throughout the state.

Both northern and southern animal types are found in New York. The wild turkey, panther, elk, moose, wolverine and timber wolf have been killed off but protective measures have saved the beaver, otter, mink and black bear from extinction. Deer, foxes, muskrats, raccoons, rabbits and squirrels are common in most parts of the state.

About 265 kinds of birds inhabit the state during some portion of the year. In the summer there are the robin, wood thrush, catbird, bluebird, wren, barn swallow, meadow lark, red-headed woodpecker and oriole among others. Year-round types include the English sparrow, crow and various kinds of woodpecker and hawk. The state protects game birds such as partridge, pheasant, ruffed grouse, varieties of wild duck, snipe and woodcock. There are a great many types of fish in New York's waters despite pollution and disturbance of the balance of nature through the stocking of streams. The kinds common in most watersheds are darters, yellow perch, suckers, bullheads, sunfish, small-mouthed bass, rock bass, shiners, dace, brook trout and blunt-nosed minnows. Long Island is noted for its shellfish: lobsters, oysters, clams and scallops. Its fishermen seek out the pollack, flounder, mackerel, bluefish, striped and sea bass in the ocean waters.

Parks and Reservations.—The state conservation department supervises 98 parks which vary in size from 6 ac. (Sackets Harbor) to 59,600 ac. (Allegany state park). The state council of parks which is composed of the chairmen of the various regional park commissions acts as a central advisory agency. The nine park commissions are Niagara frontier, which preserves the beauties of Niagara falls and gorge; Palisades interstate; Genesee, which oversees Letchworth park; Finger Lakes, which includes Watkins glen and Taughannock falls; Thousand Islands; Taconic state, which supervises 9 park areas on the east bank of the Hudson; Central New York; Long Island, which supervises 17 parks including Jones beach; and Allegany state. In addition, the state owns the Adirondack forest preserve, a virgin wilderness embracing 2,252,970 ac. In 1964 the Fire Island National Seashore, comprising 25 mi. of beach, was established.

Following the colonial practice, New York in 1784 made a treaty with Chief Joseph Brant and the six nations of the Iroquois, and assumed responsibility for the Indians residing within its borders. In 1960 about 7,000 Indians lived on seven reservations. They are the Allegany, Cattaraugus, Tonawanda and Tuscarora in the western part of the state; the St. Regis, the most populous, near Massena; the Shinnecock, on Long Island; and the Onondaga, south of Syracuse. Indian agents are appointed by the state board of social welfare and are directed to provide care and relief for needy Indians.

Historic Sites and Museums.—New York has many museums, notable buildings and historic sites. The New York State Historical association operates two museums at Cooperstown: Fenimore house, its headquarters, with historical and art collections and the Farmers' museum with its 19th-century village. Nearby is the National Baseball Hall of Fame and Museum. The Adirondack museum at Blue Mountain lake has exhibits of logging equipment, boats and early resorts. Other important historical museums are the Albany Institute of History and Art, the Buffalo Historical museum, Oneida Historical society in Utica, the Rochester Historical Society museum and the Suffolk County Historical Society museum at Riverhead. New York city has several important museums. Perhaps the most interesting historically are the Museum of the City of New York and that of the New York Historical society. Local societies throughout the state have collected Indian relics, newspapers, diaries, tools, firearms, china and furniture.

The state has acquired more than 20 historic houses and sites. Three Revolutionary War battlefields—Oriskany, Saratoga, Bennington (Walloomsac)—are marked by monuments and parks. In Kingston stands the senate house where the first state senate met on Sept. 10, 1777. Three historic places in the Newburgh area are associated with the last two years of the American Revolution. They are Washington's headquarters, Knox's headquarters and Temple hill where General Washington appealed to his rebellious officers to remain patient and loyal. Across the Hudson river are the Clinton house at Poughkeepsie, Philipse manor at Yonkers and the John Jay homestead at Bedford. The national government administers a library at Hyde Park, the home

and graves of Franklin D. Roosevelt and his wife, as a national historic site. The Albany area has three state-administered houses or museums: the Schuyler mansion, Ft. Crailo in Rensselaer and the state museum attached to the state library in Albany. The state museum specializes in Indian material and collections of the animals, flowers and minerals of the state. Johnson hall in Johnstown, Guy Park in Amsterdam and Ft. Johnson in Fort Johnson were built by Sir William Johnson, an early Indian trader and builder. The Schoharie County Historical society has its museum in the Old Stone fort in Schoharie. Near Little Falls stands the Herkimer home where the hero of the battle of Oriskany, Nicholas Herkimer, died in 1777. Three colonial forts have been reconstructed. They are Ft. Ontario at Oswego, Ft. Niagara at Lewiston and Ft. Ticonderoga. Three memorials commemorate the campaign by Generals John Sullivan and James Clinton against the Iroquois in 1779. They are the Sullivan monument near the south end of Conesus lake, the Boyd-Parker monument near Geneseo, and the Newton battlefield near Elmira. Theodore Roosevelt's home, Sagamore Hill, at Oyster Bay, L.I., and his birthplace in New York city became national historic sites in 1963. Two outstanding industrial museums are the George Eastman House of Photography in Rochester and the Corning Glass museum in Corning.

HISTORY

The Indians.—The Iroquois Indians had an important influence in New York not only on provincial development, but also on the imperial struggles between the Dutch, British and French. The five tribes (Mohawk, Oneida, Onondaga, Cayuga and Seneca) of central and western New York formed the confederacy of the Five Nations about 1570. This confederacy or league, which admitted the Tuscarora in 1722, reached the height of its influence about 1700 when it held the balance of power between England and France. The league's power rested on its commanding position on the strategic waterways, its control of the fur trade between the seacoast traders and the tribes of the interior, its unity and its skill in warfare. The various Algonkian tribes in the lower Hudson valley and Long Island were much less important.

Discovery and Exploration.—New York bay and the Hudson river were discovered by Giovanni da Verrazano in 1524. For many years after that, French vessels occasionally ascended the Hudson to trade with the Indians. Henry Hudson and Samuel de Champlain penetrated deep into the heart of New York in 1609. The Dutch East India company employed Hudson, an Englishman, to find a new water route to the far east. After a vain effort to sail around northern Europe, Hudson turned westward and finally entered New York harbour. Hudson sailed up the "river of the mountains" to a point near the site of Albany. His reports on the fertile land, furs and friendly Indians aroused much interest among Dutch merchants. The East India company sent out more sea captains to explore and trade. Adriaen Block in 1613–14 explored the shores of Long Island sound from Manhattan Island to the present state of Rhode Island. Late in 1614 or early in 1615 a stockaded trading post called Fort Nassau was erected on Castle Island within the present limits of Albany.

Settlement.—In 1621 the states-general, the ruling council of the Dutch republic, granted a charter to the Dutch West India company which gave it a monopoly of trade for 24 years along the shores of the Americas and in the Atlantic below the Tropic of Cancer. The company's directors drew up in 1624 a provisional order for administering a colony to be established in the recently designated (1623) province of New Netherland. It provided for company control of trade and for a director general. The same year it sent out about 30 families, mostly Walloons, and 18 of these families founded the first permanent settlement at Fort Orange (Albany). Three more vessels arrived in 1625 and Willem Verhulst replaced Cornelis Jacobsen May as director or governor. In 1626 the company appointed as governor Peter Minuit who purchased Manhattan Island from Indian chiefs for 60 guilders (about $24) in trinkets and built a fort at the lower end of the island. This settlement, known as New Amsterdam, became the seat of government and trade. The village grew slowly having only about 1,000 inhabitants by 1650 and about 1,500 in 1664.

In 1629 the company adopted the charter of freedoms and exemptions in order to spur colonization and agriculture. With company permission individuals could take possession of as much land as they could cultivate. Thus began the system of individual development and private ownership of land. Members of the company who peopled their tracts with 50 adult settlers in four years could acquire huge estates along navigable rivers. Only one of these patroonships proved successful, however, that of Kiliaen Van Rensselaer, a diamond merchant of Amsterdam, who developed his estate, which covered most of modern Albany and Rensselaer counties, by sending out colonists, craftsmen and supplies. His practice of leasing his land encouraged the system of farm tenancy which the English landlords later expanded.

The Dutch Period.—Governor Minuit was recalled in 1631 for granting privileges to the patroons at the expense of the company. His successor, the corrupt Wouter van Twiller (1633–38) constructed forts on the Connecticut and Delaware rivers in order to protect the fur traders. Willem (William) Kieft began his nine-year rule in 1638 when the company gave up its monopoly of trade. Two years later it permitted those who transported five settlers to the colony to receive 200 ac. and it also began to allow manufacturing. These inducements encouraged immigration from the homeland and from New England and Virginia. The activities of irresponsible traders and the mismanagement of Indian affairs by Governor Kieft, however, provoked the Algonkians to attack the Dutch settlements (1641–45). Out of this warfare arose an organized movement for a government in which the colonists would have a voice, but in 1642 Kieft refused to accept reforms which were recommended by an unofficial board of 12 leading colonists. The next year he clashed with another board of eight men over the issue of taxes and this board's request to the states-general for the recall of Kieft was granted.

Peter Stuyvesant (*q.v.*), his successor, arrived in May 1647. He agreed to the establishment of a board of nine men, the first permanent board of officials in the colony, but he rejected the board's recommendations. The grant of municipal rights to New Amsterdam in 1653 encouraged the towns on Long Island to demand more self-government. The leading men from the province met in a diet and demanded a share in the enactment of the laws and in the election of officials. Stuyvesant dismissed the meeting but the Long Island towns kept up their demands until in 1663 they secured the right to elect their own magistrates at town meetings. They also won a memorable victory for religious liberty. Stuyvesant, a zealous Calvinist, was especially angry at the rebellious town of Flushing which permitted Quaker meetings. His order forbidding Flushing to harbour Quakers led 26 freeholders to sign a remonstrance in 1657 calling for liberty of conscience. The imprisonment of one of the leaders did not stop the Quaker activities in Flushing and in 1662 Stuyvesant arrested John Bowne for allowing meetings in his house. Bowne was jailed and deported but the directors of the company urged Stuyvesant to end his persecution and eventually Bowne returned to New Netherland a free man.

Stuyvesant had more success in conducting foreign affairs. In 1655 a fleet of seven ships and 650 men which he had dispatched captured the Swedish settlements on the Delaware river founded by the New Sweden company in 1637. The English threat was potentially more dangerous. The English government claimed the whole region held by the Dutch, citing the discoveries of John Cabot (1498), the patent of the London and Plymouth companies (1606) and the patent to the council of New England (1620). Most threatening of all was the invasion of the Connecticut valley, the land along the sound and Long Island by English settlers. Realizing the weakness of New Netherland, Stuyvesant was forced in 1650 to sign the humiliating treaty of Hartford with the New England confederacy by which Long Island was divided. The English obtained the part east of a line drawn south from Oyster bay and also secured the rest

west of the Connecticut river although they agreed not to settle within 10 mi. of the Hudson river.

Trade regulation, however, led to the final conflict between England and Holland. The Dutch traders constantly interfered with the enforcement of the acts of trade and navigation. Then, on March 22, 1664, Charles II of England granted to his brother James, duke of York and Albany, all of the land from the west side of the Connecticut river to the east side of Delaware bay, including Maine, Long Island, Martha's Vineyard and other islands. Col. Richard Nicolls was appointed commander of a fleet to capture New Netherland. Stuyvesant surrendered in September without fighting and Nicolls replaced him as governor.

English Rule.—The transition from Dutch to English rule and institutions was accomplished smoothly. The duke of York assumed sole power to make laws, regulate trade, grant land and fix taxes. Completely autocratic rule, however, was limited by several factors such as the great distance from England, demands by inhabitants for home rule, the willingness of governors to make concessions in order to secure co-operation and the requirement in the duke's charter of 1664 that all laws must harmonize with those of the homeland. Governor Nicolls began in 1665 by creating an English county named Yorkshire out of Long Island, Staten Island and Westchester and promulgating a code of laws known as the "duke's laws." This code gave the freeholders of each town a voice in town government through the election of a board of eight overseers and a constable. It also guaranteed religious freedom and jury trial. The code soon was extended to the rest of the province. The duke of York had reduced his holdings in 1664 by granting New Jersey to Lord John Berkeley and Sir George Carteret and Governor Nicolls recognized Connecticut's claims to its present borders. Nicolls was succeeded in 1668 by Col. Francis Lovelace who, as governor, continued the policy of conciliation.

In Aug. 1673, Holland and England being at war, a Dutch fleet surprised and captured New York and restored Dutch authority and names. The treaty of Westminster in Feb. 1674 reaffirmed the treaty of Breda (1667), and in November the English again took possession in the person of Gov. Edmund Andros. The merchants strenuously resisted Andros' efforts to levy import duties and while he was in England to answer unfounded charges of dishonesty the citizens renewed their demands for a representative assembly. The unrest led the duke in 1683 to send a new governor, Thomas Dongan, with orders to call the desired assembly. It met in New York city and passed 15 acts, the most important of which was a charter of liberties and privileges that provided for an assembly elected by the freeholders and freemen. This assembly had the power to approve or reject all taxes. When the duke became king of England as James II in 1685, he withdrew his approval of the charter and instructed Dongan to resume full legislative powers. In 1688 he consolidated New York, New Jersey and the New England colonies into the Dominion of New England under the viceregal authority of Andros as governor general.

The news that the British parliament had dethroned James and that Boston's citizens had jailed Governor Andros led to a popular uprising in New York under the leadership of Jacob Leisler (*q.v.*). Leisler called an assembly which proclaimed James' successors, William and Mary, as monarchs and formed a committee of public safety to rule. Leisler surrendered the colony on March 29, 1691, to Henry Sloughter, the new governor. The landlord-merchant aristocracy hated Leisler for his democratic tendencies and they persuaded Sloughter and his council to bring charges of treason against Leisler who was tried, convicted and hanged. The Leisler rebellion, besides sharpening class cleavages, helped preserve New York's separate existence. It also resulted in a permanent bicameral legislature since Leisler's assembly was made a permanent elected unit and the old council became the upper house.

The rise of the assembly and of provincial home rule were the most striking developments in the political history of New York in the 18th century. The extravagances of Gov. Edward Cornbury (1702–08) caused the assembly in 1706 to demand and win the right to appoint its own treasurer when it needed to raise "extraordinary supplies" beyond the normal budget. In 1715 Gov. Robert Hunter (1710–20) agreed unofficially to spend the budget according to a system specified by the colony's leaders. Gov. George Clinton (1743–53) clashed repeatedly with the assembly, which tried to strip him of his powers even over military affairs. Finally a compromise was arranged whereby Clinton could initiate money bills but had to accept a one-year appropriation bill which named officials and fixed salaries. The great landlords of the upper Hudson, led by the Livingston family, organized a new faction in the 1750s to challenge Lieut. Gov. James De Lancey, who had agreed to a tax on land in order to raise revenue for the French and Indian War (1754–63). During the next 20 years the Livingston group in alliance with the Presbyterians, lawyers and artisans tended to challenge the royal prerogative and eventually became the patriots of the American Revolution whereas the De Lancey group, supported by the Anglican Church and the most important merchants of the city, tended to oppose radical measures and they became the Tories (Loyalists) in 1775.

The famous libel suit against John Peter Zenger (*q.v.*), who had established the *New York Weekly Journal* in 1733, advanced the freedom of the press and to some extent the independence of the judiciary. Gov. William Cosby arrested Zenger in Nov. 1734 for printing criticisms of his administration. At his trial, the jury released Zenger because it held his statements were true and therefore not libelous. In 1805 New York, after the urging by Alexander Hamilton, enlarged the freedom of the press by admitting truth as a defense in libel cases.

The northern frontier of New York was a crucial area in the long conflict between England and France for the domination of North America—thus the colony was often a battleground in the four Anglo-French wars between 1689 and 1763. Between 1713 and 1740 relative calm was maintained on the New York frontier. The French, however, built Ft. Niagara (1726) and Crown Point (1731) on Lake Champlain and Gov. William Burnet countered by building Ft. Oswego in 1727. Gov. George Clinton favoured vigorous action against the French but the assembly would vote him no money. He made William Johnson, a famous Indian trader, the Indian agent for New York but Johnson was able to win support only from the Mohawk tribe. The Iroquois complained that the land speculators stole their lands and that the government did not protect them from French attacks. To meet this dissatisfaction the colony's board of trade directed Governor De Lancey to call a colonial congress at Albany in 1754, at which Benjamin Franklin advanced his plan for colonial union. The congress adopted the plan with modifications, but the plan was ultimately disapproved by all of the colonies. The congress was partly successful, however, in placating the Iroquois.

The British plans for 1755 called for attacks on Ft. Niagara and Crown Point. Neither campaign succeeded although at the battle of Lake George the British defeated the French forces of Baron Ludwig Dieskau. In 1756 the French general Montcalm took Oswego and the following year Ft. William Henry on Lake George. Ticonderoga, Crown Point and Niagara were eventually taken from the French and Montreal fell in 1760. The final British victory in 1763 meant the end of the French threat but it also marked the decline of Iroquois power. Furthermore, it set in motion the forces which led the colonists to seek home rule and finally independence.

The Revolutionary Period.—Victory brought perplexing problems to Great Britain. Among them were a large debt, heavy taxes, the administration of new territories and the necessity of reorganizing the imperial trade. In wrestling with these problems cabinet ministers advanced solutions which encroached upon the home rule of the colonists. The Sugar act of 1764 with its provision for vigorous enforcement provoked the merchants who were suffering from the postwar depression and a currency shortage. Irritation became anger when parliament in 1765 passed the Stamp act, which imposed a tax on legal documents, licences, commercial instruments, newspapers, pamphlets, etc. The New York assembly authorized a committee to correspond with committees in other colonies and to attend a Stamp Act congress which met in

New York city in 1765. The Sons of Liberty, a radical group of artisans led by lawyers and merchants, rioted, boycotted British imports and threatened stamp officials. The good feeling caused by the repeal of the Stamp act in 1766 turned to dismay when Gov. Henry Moore prorogued the assembly in late 1766 until it should provide for quarters and supplies for British soldiers. The Townshend acts of 1767, designed to raise further revenue, stirred merchants to sign a nonimportation agreement. Finally, in 1770 parliament repealed the duties except the tax on tea.

Tension relaxed until 1773 when the Tea act was passed. This act annoyed most merchants because it gave the British East India company the right to sell tea through its own agents. Following the example of Boston, a band of men disguised as Indians were dispatched to dump tea into New York harbour. When parliament passed the "Intolerable acts" in retaliation, the New York assembly appointed a committee which approved the calling of a continental congress. The first continental congress in Oct. 1774 adopted the "association," an agreement not to import from or export to Britain until American rights were respected. A committee was to be set up in each town, city and county in each of the English colonies in North America to enforce the association by punishing violators. (*See* CONTINENTAL CONGRESS, THE.) This action disturbed the conservative majority in the assembly who refused to choose delegates to the second continental congress, but the radicals asked county committees to send representatives to a provincial convention which met on April 20, 1775, and appointed the delegates.

News of the battle of Lexington on April 19, 1775, led to the collapse of royal government in New York. The radicals formed a committee of 100 which in effect governed New York until the second provincial congress met on May 22.

There was never a majority of New Yorkers who favoured severing the imperial tie. Loyalist sentiment was perhaps stronger in New York than any other state. Traditional ties of family, church and trade were reinforced by the fear of radicals and the destruction of trade by the association. Real power, however, passed to the third provincial congress which met in May 1776 and called for a new government. This congress refused to permit the New York delegates to the second continental congress to sign the Declaration of Independence on July 4, but the fourth provincial congress, meeting at White Plains, approved the famous document July 9.

Nearly one-third of all the engagements of the Revolutionary War took place in New York. George Washington came to New York city on April 13, 1776, to prepare against an attack. Britain's Sir William Howe landed with 10,000 men on Staten Island on July 5. He ousted the Americans from Brooklyn and occupied New York city on Sept. 15. Gen. John Burgoyne with 7,700 British and German troops took Ft. Ticonderoga on July 6, 1777, but surrendered his forces at old Saratoga (Schuylerville). Meanwhile, the British colonel Barry St. Leger led an auxiliary force from Oswego against Ft. Stanwix (Rome). On Aug. 6 he fought one of the bloodiest battles of the war at Oriskany, where the American commander Nicholas Herkimer was mortally wounded. Deserted by his Indian allies, St. Leger retreated to Oswego. Sir Henry Clinton, who had been left in charge by Howe, led a small expedition up the Hudson, broke through the highland barrier and burned Kingston. When he learned of Burgoyne's imminent defeat, Clinton decided to withdraw to New York city. The failure of the British campaign not only saved upstate New York and New England, but it persuaded France to enter the war as an American ally. Frontier attacks by Tories and Indians caused much damage in the Mohawk and Schoharie valleys. As a result in 1779, the American generals John Sullivan and James Clinton advanced through the Finger Lakes region to the Genesee valley where they burned about 40 Iroquois villages. The closing episode of the war as far as New York was concerned was the discovery of Benedict Arnold's attempt in 1780 to betray West Point and other posts on the Hudson to the British. Washington established his headquarters at Newburgh after the British surrender at Yorktown in 1781. The British left New York city on Nov. 25, 1783, but did not give up their posts on Lake Ontario until 1795 after the signing of the Jay treaty in 1794. (For further details, see AMERICAN REVOLUTION.)

Early Years of Statehood.—John Jay was the principal author of New York's first constitution. The structure of government was quite similar to that of colonial New York although the power of the governor was curtailed. Both Jay's appointive and veto power had to be shared with councils which included senators. These councils worked badly and the constitutional convention of 1821 abolished them. In 1777 George Clinton became the state's first governor and held the office for the next 18 years. He was a champion of the patriots against the Tories, of states' rights against central government and of small farmers against the landed aristocrats. The conservatives wanted a strong government and their leader, Alexander Hamilton, helped call the Constitutional convention in 1787 and he alone of the New York delegation signed the federal constitution which the convention adopted. Nevertheless, his opponents composed about two-thirds of the delegates to the state convention called to ratify the federal constitution in 1788. A bare majority for ratification was obtained as the result of Hamilton's arguments, the ratification by New Hampshire and Virginia, a promise of a bill of rights and the threat of secession by New York city. All New Yorkers supported Washington for president and were pleased by the choice of New York city as the temporary national capital.

The friends and foes of the federal constitution continued their rivalry under the designations of Federalists and Antifederalists (Clintonian Republicans). Most of the aristocracy, except for the Livingston family, backed Hamilton whereas a majority of the farmers supported Clinton. Aaron Burr transformed Tammany hall from a fraternal association into an arm of the Republican (future Democratic) party. The Federalists easily elected Jay as governor in 1795. Jay reformed the criminal code and pushed through a law in 1799 providing for gradual emancipation of slaves. The Federalists, however, lost popular support because of their attempts to prosecute Jedediah Peck and other critics of Pres. John Adams under the federal Sedition act.

The return of Clinton as governor in 1801 inaugurated a period of factional strife among his Republican followers. His nephew De Witt Clinton, challenged Aaron Burr's political control of New York city and became mayor in 1803. Burr in 1804 ran for governor as an independent with Federalist backing. Hamilton's advice to his friends not to vote for Burr added to Burr's hatred of Hamilton and this enmity led to a duel between the two men in which Hamilton was killed. Thereafter, the Federalists declined although the party experienced a temporary revival when the Embargo act and the War of 1812 injured trade and shipping.

Gov. Daniel D. Tompkins (1807–17) proved an exceptional war leader during the War of 1812. Tompkins surmounted such difficulties as the poorly trained militia, obstructive tactics by the Federalist majority in the assembly and incursions by the British. Many of the war's battles were fought along the state's borders. The American plan for an attack on Niagara and Montreal ended ingloriously largely because the state's militia refused to advance beyond the state's borders. British raids on Plattsburgh and Buffalo and the American burning of York (Toronto) occurred in 1813. The next year Capt. Thomas Macdonough defeated a larger British fleet on Lake Champlain and prevented an invasion.

De Witt Clinton's speech in 1815 demanding canals between the Hudson river and Lakes Erie and Champlain met such an enthusiastic response the legislature was forced to make Clinton the head of a canal commission.

Power Politics.—In 1817 Clinton became governor by an almost unanimous vote and, largely through his efforts, the Erie canal was built. About this time, Martin Van Buren and other Republicans such as William L. Marcy and Silas Wright organized a powerful political machine known as the Albany Regency. This group favoured low taxes, fiscal economy and no government interference with business. At the constitutional convention of 1821 Van Buren reflected the democratic spirit of the day by extending the vote to all white males over 21, but his group refused to give Negroes the vote unless they could meet high property qualifications. The Regency elected Joseph C. Yates in 1822 and ousted

Clinton from the canal commission in 1824. This blunder enraged public opinion and Clinton was swept back into the governor's office in 1825 just in time to open the Erie canal that year.

New York politics was especially complicated in the period from 1825 to 1865. The two-party system tended to break down because of the almost continuous splits within the major parties and the emergence of several new parties. The principal issues were the role of government toward canals and railroads, the extension of slavery to the territories, prohibition of liquor, immigrants and the chartering of banks. Thurlow Weed and William Seward used the Antimasonic party (*q.v.*) to attack the Albany Regency, which had granted many bank charters to its friends. Weed finally cemented an alliance between the Antimasons and most of the followers of De Witt Clinton. This alliance became known as the Whig party and was the main opposition to the Democratic party between 1834 and 1855.

Seward became the first Whig governor in 1838. The Whig program called for the enlargement of the Erie canal and more aid for education. A piece of significant legislation was the Free Banking act of 1838, under which individuals or associations could engage in banking without any special charter provided they had a paid-up capital of $100,000. The Democratic party was split between the "Hunkers" or conservatives and the "Barnburners" or radicals. The conservatives urged the use of canal revenues to complete the canals while the radicals wanted to pay off the state debt. The Barnburners opposed the extension of slavery into the territories, but the Hunkers co-operated with the southern Democrats who often controlled the presidency and the national congress. In 1848 the Barnburners created the Free-Soil party and chose Martin Van Buren to run for president. The Democratic split guaranteed a Whig victory for Hamilton Fish as governor and Zachary Taylor as president. But the slavery issue also split the Whigs and the factional fight within the party led to its collapse by 1855. The mortal blow came with the Kansas-Nebraska act of 1854, which led to the formation of the Republican party. Weed, William Seward and Horace Greeley were three of the prominent Whigs who joined the Republicans along with several Barnburners and Free-Soilers. The Republican party attracted upstate farmers and small businessmen and in 1856 elected John King as governor.

The national crisis of 1860–61 bewildered New Yorkers, but under the able direction of Republican Gov. Edwin Morgan the state provided supplies, money and almost 500,000 soldiers for the ensuing Civil War. The unfair provisions of the draft act and its clumsy administration were the causes of the draft riots of July 1863 in New York city.

New York citizens took the leadership in the humanitarian movement that characterized the period between 1830 and 1860. The state supplied several leading reformers—Thomas Eddy, Gerrit Smith, Susan B. Anthony, Theodore Weld—in such fields as penology, mental care, temperance, women's rights and antislavery agitation. Washington Irving and James Fenimore Cooper established the state's literary reputation before 1825, after which New England authors marched to the fore. Walt Whitman and Herman Melville after 1850 re-established the leadership of New York in literary affairs. In music, art and the theatre, New York city became pacesetter for the nation.

New York became the "Empire state" by 1830 when it was first in population, agriculture, foreign trade, manufacturing and transportation facilities. The influx of hundreds of thousands of Yankees meant the rapid clearing of forests, stimulation of trade and the growth of factories. The most significant developments in the land history of the state were: the treaty of Hartford of 1786 by which Massachusetts gave up its claims to western New York in return for the land west of Seneca lake plus ten townships near Binghamton; the purchase of land titles from the Indians by Massachusetts and New York agents; the sale of huge tracts to such speculators as Robert Morris, the Holland Land company and the London associates; the rapid distribution of land into the hands of small farmers; the collapse of the old leasehold system; and the rise of speculation in urban real estate from New York city to Buffalo.

"Boss" Rule and Corruption.—During the decade following the Civil War, "boss" rule and corruption characterized government operations on the state, county and city levels. Postwar demoralization, the antiquated government structure, the pressure of business interests for franchises and contracts, the strengthening of political machines such as that of Boss William Tweed were the major causes of corruption. The Democratic party generally controlled the governorship between 1875 and 1895 under such important leaders as Samuel Tilden (1875–76), who broke up the "canal ring" (*see* TILDEN, SAMUEL JONES), Grover Cleveland (1883–84) and David B. Hill (1885–91). During these years the Republican party was divided by factional strife with the leader Roscoe Conkling quarreling with Republican presidents Rutherford Hayes, James Garfield and Chester Arthur, for control of patronage especially in the New York custom house. The governorship passed to Republicans between 1895 and 1910 because the public charged the Democrats with corruption and responsibility for the depression of 1893 and because the Republicans were ably led by Theodore Roosevelt and Gov. Charles Evans Hughes. Hughes (1907–10) brought about the regulation of insurance and utility companies, introduced many labour reforms, including the first workmen's compensation law, and took steps to conserve forest and water resources. The split between the progressive followers of Theodore Roosevelt and the conservative Republicans gave the state to the Democrats in 1910 and 1912. An intraparty fight between Democratic Gov. William Sulzer and Boss Charles Murphy of Tammany hall led to the impeachment of Sulzer in 1913. He was found technically guilty of perjury, misrepresentation of campaign expenditures and concealment of evidence. More important than these quarrels were the labour laws passed after the diastrous Triangle shirtwaist factory fire in New York city in 1911. Robert Wagner, with the aid of Alfred E. Smith, made a thorough examination of labour conditions and their recommendations were enacted into legislation. Among the laws passed was the Widowed Mothers Pension act.

Modern Times.—The Democratic party usually controlled the governor's office from 1918 to 1942 because of the ability of its able leaders such as Smith, Wagner, Franklin D. Roosevelt and Herbert H. Lehman to attract the votes of the foreign-born and their children in the cities. Most immigrants preferred the Democratic party because of its traditional hospitality to immigrants as opposed to the nativistic tendencies of the Federalist-Whig-Republican group; its opposition to prohibition; its sympathy toward labour; and its willingness to use government agencies to combat the depression of 1930.

The structure and scope of New York's government has been transformed, especially since 1922. Governor Smith (1919–20; 1923–28) left an impressive record despite the obstructive tactics of the Republican-controlled legislature. Smith aroused public opinion to force through his program including the consolidation of 187 bureaus into 18 departments; the executive budget; "home rule" for cities; more state aid to localities for roads, health and education; the expansion of the park system; the eight-hour day; the retention of public power sites; and the expansion of the mental hygiene program. Gov. Franklin D. Roosevelt (1929–33) continued Smith's policies despite the onset of the economic depression in 1930. He arranged for work relief for the unemployed and started a system of old-age pensions. In 1932 Roosevelt succeeded in removing James Walker, colourful mayor of New York city, whose administration was tainted with corruption. The Smith-Roosevelt experiments in social legislation anticipated much of the federal New Deal legislation of the 1930s.

Among the policies of Governor Lehman (1933–42) were more stringent regulation of public utilities, low-cost housing projects, minimum wages for women, close regulation of the dairy industry, the extension of the merit system to practically all government departments, a liberal welfare program and a balanced budget. In 1942 Thomas E. Dewey, a Republican lawyer who had made a reputation prosecuting rackets in New York city, became governor, a position which he held until Jan. 1, 1955. Dewey continued Lehman's efforts to expand agricultural and industrial production for defense during World War II. The state division of commerce sought and secured many government contracts for

New York firms. More than 1,000,000 workers were trained and the state and federal labour boards were successful in settling almost all labour disputes. A special war council co-ordinated efforts to solve such problems as the shortage of farm labour, feed and gasoline, civilian defense, vocational training and food conservation. The Ives-Quinn act of 1945, the first state law of its kind, forbade discrimination in employment. Its chief purpose was to educate employers to hire the best qualified candidates. The five-man commission established by the act was given authority, however, to issue cease and desist orders against violators of its orders. Another achievement was the creation of the state university in 1948, which consolidated the existing state institutions of higher learning and also encouraged the establishment of new two-year community colleges. Under Dewey the health services were greatly expanded and in 1948 the thruway was begun. His administrations won for Dewey national attention, but he failed in his two campaigns for the presidency.

W. Averell Harriman, a Democrat, barely defeated Republican senator Irving Ives in 1954. Harriman's administration continued the policies begun by Smith, Roosevelt and Lehman and continued by Dewey. Harriman lost his bid for re-election in 1958 to Nelson Rockefeller, who won office by more than 500,000 votes and was re-elected in 1962 and again in 1966. His program continued the enlargement of social services and tax reforms.

GOVERNMENT

New York has been governed under five constitutions which were adopted in 1777, 1821, 1846, 1894 and 1938 respectively. The constitution of 1938 has 20 articles, including a bill of rights. It grants the vote to all citizens of 21 years or over who have resided within the state for 1 year, in the county for 4 months and in the election district for 30 days. Voters must also be able to read and write English. The constitution provides for revision in two ways. Every 20 years the voters are given the opportunity to approve or reject the convening of a constitutional convention. Any changes by a convention must receive the approval of the voters in the next election. The more frequently used method of revision, however, is passage of legislation by two consecutive sessions of the legislature after which the proposed changes are submitted to popular referendum.

The governor of New York is a strong executive whose prominent position often makes him a presidential possibility. He is elected for a four-year term along with a lieutenant governor, comptroller and attorney general. Among the duties and powers of the governor are the construction of the budget, the appointment and removal of many officials, law enforcement, the approval or veto of legislation and the command of the state militia and police. In the event of the death, impeachment, resignation or absence of the governor, the lieutenant governor becomes the chief executive.

A constitutional amendment of 1944 added a department of commerce to the state's organization; an amendment in 1959 added the department of motor vehicles. The other state departments are those of audit and control, taxation and finance, law, state, public works, conservation, agriculture and markets, labour, education, health, mental hygiene, social welfare, correction, public service, banking, insurance and civil service. In addition there is an executive department directly under the control of the governor.

The legislative power is vested in a senate of 58 members and an assembly of 150 members, each chamber elected biennially. Both senators and assemblymen are elected from single districts. Republican control of the legislature and the constitutional conventions of 1894 and 1938 has led to the apportionment of seats in such a way as to favour upstate and rural counties over New York city. The legislature meets each year. Most of the work is done by committees whose chairmen have great power in determining what bills will receive approval. Bills approved by both houses are sent to the governor for his signature or veto. The governor has 30 days to study any bills sent within the last ten days of a session, but a bill must have his signature to become law.

The court structure defied systematic reorganization from 1846 until 1962 when, under a constitutional amendment adopted in 1961, centralized administration by a five-man board of the state highest judges was established, a family court was created and courts in New York city, reorganized in 1959, were consolidated. Most judges are elected, usually for a 14-year term. The court of appeals, the state's highest court, consists of a chief justice and six associate justices elected from the state at large. This court reviews only questions of law except in cases in which the death penalty is involved.

The state is divided into eleven judicial districts each of which has several supreme court justices. The supreme court has general jurisdiction in law and equity, including both civil and criminal actions. There are four judicial departments in which appellate divisions of the supreme court are established. These courts review cases from the supreme and inferior courts. The governor selects the justices who sit on the appellate division. The court of claims consists of six judges appointed by the governor and approved by the senate for nine-year terms. It hears and determines private claims against the state.

Each of the 62 counties (unless wholly included in a city) has its own officials. The voters elect the more important officials such as the county judge, surrogate, sheriff, district attorney, clerk, treasurer and coroner. A board of supervisors which has one supervisor from each town and city ward has executive, legislative and financial powers. The five counties within New York city (*q.v.*) operate under a different pattern and a few counties such as Nassau and Westchester have created the elective position of county executive. Towns provide government for those citizens living outside the borders of cities. Within the towns are villages whose government is organized according to which one of the four classes they belong. Second class towns (generally those under 10,000 population), the most numerous, are governed by a board consisting of the supervisor, two councilmen and two justices of the peace. Cities range in size from Sherrill with about 2,000 people to New York city. Most cities are administered by a mayor and a city council or board of aldermen.

Finance and Taxation.—The state is financed through the general fund which is divided into two subsidiary funds; the local assistance fund from which appropriations are made in support of units of local government and the state purposes fund from which appropriations are made for the operation of state departments and for debt service. The state's capital construction is provided for through the capital construction fund.

The constitution requires that on or before Feb. 1 of each year the governor shall submit a budget to the legislature. The budget contains a complete plan of expenditures for the next fiscal year and also the year's estimated revenues. State expenditures and revenues rose sharply after World War II. The budget for the fiscal year beginning April 1, 1946, called for the expenditure of about $600,000,000; 15 years later the figure was about $2,000,000,000 of which local governments received over $1,000,000,000. State aid for local education increased from about 24% of the total budget to about 33% for the same period. New York spent more money per pupil than any other state. At the same time the state government spent almost 35% of the total budget for its own departments. The largest expenditure was for mental hygiene followed by public works and correction. In addition, about $300,000,000 annually was appropriated from the separate capital construction fund, most of which was assigned to highways, parkways and grade crossings.

In 1959 the legislature raised taxes on gasoline and on cigarettes and the income tax was placed on a withholding basis and the maximum rate raised to 10% on taxable income over $15,000. The chief kinds of taxes in New York are individual income taxes, corporation net income taxes, motor fuels taxes, motor vehicle and operators licences, tobacco products taxes, alcoholic beverage taxes and property taxes. New York ranked after Connecticut and Delaware in size of per capita income. In the 1960s it was about $3,000.

The state banking department was created in 1851. It is required to examine every bank, trust company and other financial institution within the state but not the national banks. In the second half of the 20th century there were about 500 banks

the state with total assets of more than $75,000,000,000. At the same time the assessed value of property subject to state and local government tax was more than $35,000,000,000.

POPULATION

The population of New York remained scanty and scattered throughout the colonial period. In 1664 there were fewer than 10,000 inhabitants of whom about two-thirds were Dutch; the others were divided between Swedes, French, Germans, Negroes and English. It is estimated that the population was about 19,000 in 1700 and about 75,000, 50 years later. The figure was about 170,000 at the time of the American Revolution and included approximately 20,000 Negroes. Practically all of these persons lived within a few miles of the Hudson river or the Atlantic ocean. The emigration of more than 25,000 Loyalists (Tories) during and after the Revolution was more than offset by the great influx of New Englanders after 1783. The first federal census of 1790 revealed New York had 340,120 inhabitants. This made it fifth among the 18 states and territories that then composed the union. Approximately one-half of the white population in 1790 was of English descent with the large families of Connecticut as important a source of English blood as the United Kingdom itself. Long Island east of Brooklyn was a Yankee stronghold; the Dutch element, less than one-fifth of the total, was strong in Albany and in Ulster county. Germans from the Palatinate district along the Rhine were scattered through the Schoharie valley, the upper reaches of the Mohawk river and the Hudson valley. The small French contingent settled in New York city, New Rochelle and New Paltz. Scots from northern Ireland and Scotland were numerous in Orange and Ulster counties and in the Cherry Valley region. The Negro minority, the largest among the northern colonies, became relatively less important after the American Revolution, when immigration from New England and Europe increased.

More than half of the 1,372,812 inhabitants of New York in 1820 were of New England descent. At that time, fewer than 15% of the people lived in urban centres of more than 3,000 persons. New York became the nation's most populous state in 1820 and has remained so ever since. Another wave of immigration flooded New York between 1840 and 1860 when great numbers of Irish and Germans poured into the state. In 1855 persons born in Europe constituted more than one-fourth of the people of the state and nearly one-half of the population of New York city. In 1860, just before the Civil War, the population was 3,880,735, nearly two-fifths of which was centred in urban places.

The Irish and Germans provided the largest number of immigrants until about 1890 at which time the influx of Italians, Russians, Poles and Greeks increased rapidly until World War I. The restrictions placed on immigration by congress during the 1920s checked the number of immigrants and the economic depression of the 1930s brought immigration to a virtual standstill.

In 1960 New York had a population of 16,782,304, an increase of 1,952,112 or 13.2% over 1950. The population per square mile in 1960 was 338.5, as compared with 49.6 for the U.S. as a whole. The percentage of persons 65 years old or over was increasing, being 10.1% in 1960. The percentage of the population 14 years old and over that was in the labour force (56.5% in 1960) was steadily increasing, the result of prolonged schooling for that age group. Foreign-born whites numbered 2,181,868 in 1960 with the Italians (430,843) and English (406,128) in the lead. In 1960 New York city with about half of the state's population had more than 67.1% of the foreign-born white residents in the state. About 48.6% of the city's residents were foreign born or of foreign or mixed parentage. Comparable figures for other centres were 48.1% for Yonkers; 37.8% for Rochester; 35.4% for Buffalo.

In 1960 seven standard metropolitan statistical areas—Albany-Schenectady-Troy (Albany, Rensselaer, Saratoga, Schenectady counties), Binghamton (Broome county), Buffalo (Erie, Niagara counties), New York (*see* NEW YORK [CITY]), Rochester (Monroe county), Syracuse (Madison, Onondaga, Oswego counties) and Utica-Rome (Herkimer, Oneida counties)—had a combined population of 14,352,693. In 1963 Tioga county (pop. [1960] 37,802), N.Y., and Susquehanna county, Pa. (33,137) were added to the Binghamton SMSA and Livingston (44,053), Orleans (34,159) and Wayne (67,989) counties were added to the Rochester SMSA.

EDUCATION

Historical and Administrative.—A majority of the children in colonial New York never saw the inside of a schoolroom. In New Amsterdam schools were established under church auspices and with government support beginning in 1638. Under the British the Society for the Propagation of the Gospel in Foreign Parts set up a few schools for the children of the Indians and the poor. Middle-class families often employed tutors or sent their children to private schools. The few youths preparing for the ministry or the law attended college usually at Yale or Princeton (then the College of New Jersey). The Anglicans founded King's college (later Columbia university) in 1754. During the Revolutionary War most of the schools were closed.

In 1784 the legislature established a system of education which was supervised by a board of regents and was authorized to establish secondary schools and colleges. Later the board's functions were extended to include the jurisdiction of the professional, scientific and technical schools, the administration of laws relating to the admission to the professions, the charge of the state library at Albany, the supervision of local libraries and the custody of the state museum. Although the regents proposed a public-school system in 1787, little was done until 1795 when the legislature granted money for five years to elementary schools under county sponsorship. In 1812 the legislature provided for a permanent system of public schools with school districts in each township. By 1828 schools had been established in more than 8,000 districts. These schools received funds from the state, the locality and the parents of the children attending them. As many parents could not or would not pay the fees there was a movement for free public schools. The legislature in 1851 granted $800,000 for schools but it was not until 1867 that all the elementary schools became free.

Secondary schools called academies were founded by private groups with some financial assistance from the regents. Such schools charged tuition and prepared students for college. During the 1850s a few cities began to set up free public high schools. After the Civil War the movement swept across the state and most academies were taken over by the public high schools. The larger church groups founded colleges principally as a place where they could train young men for the clergy.

The legislature in 1904 reorganized the educational system. While the regents kept authority over colleges and universities, a commissioner of education was made responsible for elementary and secondary education. The commissioner became the chief officer of the whole educational system.

Among the major educational trends in the 20th century have been expanding enrollments; broader curriculums; consolidation of district schools into centralized schools; increase in state aid to localities; and expansion of publicly supported colleges and universities. The consolidation or centralization of school districts has proceeded rapidly until fewer than 10% of the original districts remained in the second half of the 20th century. This trend was encouraged by a law of 1925 which granted additional state aid

districts setting up centralized schools.

The State University of New York, established by the legislature in 1948, comprises the university centres, two medical centres, the Graduate School of Public Affairs, two-year and four-year state colleges and locally sponsored two-year community colleges. The university offers programs in liberal arts and science engineering, home economics, industrial and labour relations, veterinary medicine, ceramics, agriculture, forestry, maritime service, teacher education, law, pharmacy, medicine, dentistry, social work and business administration. Two-year programs are offered in a variety of fields, liberal arts and technical courses in agricultural, industrial, health and service areas. Several of its colleges offer graduate programs. The university is governed by a board of trustees appointed by the governor. Each college is locally administered. Units of the university include State university at Albany, State university at Buffalo, State university at Stony Brook and State university at Binghamton; Downstate Medical centre at Brooklyn and Upstate Medical centre at Syracuse; Graduate School of Public Affairs at Albany; colleges at Brockport, Buffalo, Cortland, Fredonia, Geneseo, New Paltz, Oneonta, Oswego, Plattsburgh and Potsdam; College of Forestry at Syracuse university; Maritime college at Fort Schuyler (New York city); College of Ceramics at Alfred university; and four colleges at Cornell university (agriculture, home economics, veterinary medicine and industrial and labour relations). Two-year agricultural and technical institutes are at Alfred, Canton, Cobleskill, Delhi, Farmingdale and Morrisville. Two-year community colleges under the university are located throughout the state.

The City University of New York (formerly College of the City of New York) comprises the municipal four-year colleges administered by the board of higher education of the city of New York. The colleges are City college (1847), Brooklyn college (1930), Hunter college (1870) and Queens college (1937). Under federal control are the United States Military academy at West Point, founded in 1802 and the United States Merchant Marine academy at Kings Point, founded in 1938. Columbia university (*q.v.*) in New York city, one of the nation's most famous schools, was founded in 1754 as King's college. Its activities suspended during the Revolutionary War, it was reopened in 1784 as Columbia college under a charter granted by the state of New York. By an act of the state legislature the name of the institution was changed in 1912 to Columbia University of the City of New York. Barnard college (1889) in New York city is the undergraduate college for women of Columbia university.

Among the other notable privately controlled colleges and universities in New York are Colgate university (Hamilton, 1819); Cooper Union (1859), founded by Peter Cooper; Cornell university (Ithaca, branches at New York city, Geneva and Buffalo, 1865), especially noted for its agricultural and medical schools; Fordham university (New York city, Roman Catholic, 1841); Hamilton college (Clinton, 1793); New York university (New York city, 1831); Sarah Lawrence college (Bronxville, 1926), for women; and Vassar college (Poughkeepsie, 1861), for women. Other privately controlled colleges and universities in the state include, in New York city: College of Mount St. Vincent (Roman Catholic, 1910), Finch college (1900), Jewish Theological Seminary of America (1887), Juilliard School of Music (1905), Manhattan college (Roman Catholic, 1853), Manhattan School of Music (1917), Mills College of Education (1909), New School for Social Research (1919), Pace college (1906), Yeshiva university (Jewish Orthodox, 1886); in Brooklyn: Long Island university and C. W. Post college (Brooklyn and Greenvale, 1926), Polytechnic Institute of Brooklyn (1854), Pratt institute (1887), St. Francis college (Roman Catholic, 1884), St. John's university (Roman Catholic, 1870), St. Joseph's College for Women (Roman Catholic, 1916); in Buffalo: Canisius college (Roman Catholic, 1870), D'Youville college (Roman Catholic, 1908), Mount St. Joseph Teachers college (Roman Catholic, 1937), Rosary Hill college (Roman Catholic, 1947); in Rochester: Nazareth college (Roman Catholic, 1924), Rochester Institute of Technology (1829), St. John Fisher college (Roman Catholic, 1948), University of Rochester (1850). Among other New York schools are Adelphi university (Garden City, 1896); Alfred university (1857); Bard college (Annandale-on-Hudson, 1860); Clarkson College of Technology (Potsdam, 1895); College of New Rochelle (Roman Catholic, 1904); College of St. Rose (Albany, Roman Catholic, 1920); Elmira college (1855); Good Counsel college (White Plains, Roman Catholic, 1923); Hartwick college (Oneonta, related to United Lutheran Church, 1928); Hobart and William Smith colleges (Geneva, Hobart, an affiliate of Episcopal Church, 1822); Hofstra university (Hempstead, 1935); Houghton college (Wesleyan Methodist, 1883); Iona college (New Rochelle, Roman Catholic, 1940); Ithaca college (1892); Keuka college (Keuka Park, affiliate of American Baptist Church, 1892); Le Moyne college (Syracuse, Roman Catholic, 1946); Manhattanville College of the Sacred Heart (Purchase, Roman Catholic, 1841); Maryknoll Teachers college (Roman Catholic, 1931); Niagara university (Roman Catholic, 1856); Notre Dame College of Staten Island (Roman Catholic, 1931); Rensselaer Polytechnic institute (Troy, 1824); Russell Sage college (Troy, 1916); St. Bernardine of Siena college (Loudonville, Roman Catholic, 1937); St. Bonaventure university (St. Bonaventure, Roman Catholic, 1859); St. Lawrence university (Canton, 1856); Skidmore college (Saratoga Springs, 1911); Syracuse university (founded by Methodist Church, 1870); Union college and university (Schenectady and Albany, 1795); Utica college (1946); Wagner college (Staten Island, related to the United Lutheran Church of America, 1883); Webb Institute of Naval Architecture (Glen Cove, 1889); and Wells college (Aurora, 1868).

HEALTH, WELFARE AND CORRECTIONS

Until the latter part of the 19th century private charity or the almshouse were the chief means of caring for the unfortunate but gradually public agencies expanded their scope of activities to include suitable care to dependent children, the mentally ill, the aged and infirm and the destitute. Local, state and federal governments participate and co-operate in the administration and financing of welfare services.

Public health services in New York are handled largely through the department of health and the department of mental hygiene. The latter has the largest staff and budget of all of the state's departments and cares for more than 100,000 mental patients in 18 hospitals. It also administers six state schools for mental defectives, one colony for epileptics, one psychiatric institute for research in New York city and one psychiatric hospital for observation in Syracuse. The department of health is responsible for the administration and enforcement of the public health laws and state sanitary code. It supervises all the local health agencies except those of New York city. Despite spectacular progress in diminishing the death rate from tuberculosis, the department, in the second half of the 20th century, still operated sanitoriums at Oneonta, Ray Brook and Mt. Morris. The department also sponsors research in the treatment and care of cancer at the Roswell Park Memorial institute in Buffalo and the Rehabilitation hospital at West Haverstraw. The five regional health offices of the state, located at Albany, Buffalo, Syracuse, Rochester and White Plains carry out programs in their regions and aid local agencies.

The welfare services offered by New York are administered by many departments. For convenience, however, public welfare functions are understood to mean the services controlled by the department of social welfare established in 1867 although under a different name. This department in 1873 received authority to visit and inspect all charitable and correctional institutions whether supported by state, local government or private funds. In the second half of the 20th century it supervised nearly 2,500 agencies including about 600 hospitals and dispensaries, more than 400 homes and orphanages and more than 100 child-placing organizations. At the same time, it supervised more than 60 local public welfare districts, granting them financial aid for such programs as old-age assistance, aid to the disabled, assistance to the blind, home relief, veteran aid, foster care of children and other programs.

The change in title from prison department to department of correction in 1925 indicated a significant change in attitude toward

offenders. The main concern was no longer to punish but to restore prisoners to a useful position in society. New York has pioneered in penology as is shown in the development of the Auburn system (*see* PRISON: *Silent System*) and the establishment of the first state reformatory. Six prisons are of the maximum security type: they are Attica, Auburn, Green Haven, Clinton prison at Dannemora, Great Meadow at Comstock and Sing Sing at Ossining. Wallkill prison and Westfield state farm at Bedford Hills are medium security prisons. Reformatories for boys and young men are those at Elmira and the vocational institute at West Coxsackie. Other special institutions are located at Albion, Woodbourne and Napanoch. The state hospitals for the criminal insane are Matteawan at Beacon and Dannemora.

New York has had a department of labour since 1901. It enforces laws designed to protect the health and safety of employees; to improve working conditions; to establish minimum wages; to provide benefits to workers eligible for unemployment insurance, workmen's compensation and disability benefits; and to promote peaceful labour relations.

THE ECONOMY

Living Conditions.—New York state residents have one of the highest standards of living in the world. In the second half of the 20th century wages and salaries accounted for 68% of all income flowing to New Yorkers, a substantial increase over the 56% for 1929. Property income in the same period fell, however, from 30% to 15%. Proprietors' income was 9%, a figure lower than the national average because of the lesser role played by agriculture in the economy of the state. Other income, including transfer payments and fringe benefits, have tripled since 1929 and accounted for 5.7% of the total.

Income and living conditions improved substantially after World War II. Median income per family reached $5,500 ten years after the war. New York differed from the rest of the U.S. in that there was a much higher percentage of residents engaged in clerical and sales work and a much lower percentage engaged in farming. Nearly 10% of the employed persons in the U.S. lived in New York.

Housing standards in New York are markedly higher than the national average. By the second half of the 20th century more than 83% of the dwelling units had private baths, toilets and hot water; about 90% had mechanical refrigeration and about 82% had central heating. Approximately 11.1% of the houses dated from 1940 or later; almost 53% were built before 1919. Since 1950 a large number of one-family units have been built in the suburban areas.

Agriculture.—Good soil, excellent transportation facilities and nearby markets have kept New York an important agricultural state. The value of farm products totaled more than $800,000,000 in the second half of the 20th century.

The economy of colonial New York was based on agriculture, which supported more than 80% of the people. The colonial aristocracy acquired an unusually large share of the land because of close relations with the governors. Most of the landlords rented their lands for perpetuity or for the lives of the two or three persons named in the lease. Westchester county had six manors which covered more than half its total acreage. Scarsdale, Cortlandt Manor and Philipse Manor included about 400 sq.mi. Livingston Manor, the seat of one of the most distinguished families in New York history, included 160,000 ac. while Van Rensselaer Manor covered about 750,000 ac. surrounding Albany. Tenants owed the Van Rensselaer family 10 to 14 bu. of wheat for each 100 ac., four fat hens and one day's service with a team. When the tenant sold his farm he had to pay an alienation fee of from one-tenth to one-third of the sale price.

This land system retarded the development of upstate New York since few immigrants wished to become tenants when freehold farms were obtainable in Pennsylvania, New Jersey and New England. The tenants, resentful of their economic and political inferiority, rose up in revolt on several occasions. In the 1760s antirent agitation swept through the leasehold areas on the east bank of the Hudson but the governor sent troops to put down the rebellion. The tenants, however, won some victories. The confiscation of loyalist (Tory) estates during the Revolution broke up the manors and estates along the lower Hudson, but the farmers in Albany, Rensselaer, Columbia, Schoharie and Delaware counties had to wait until the 1840s for an end to the leasehold system.

The rise of commercial farming came hard on the heels of the conquest of upstate by pioneer farmers. At first, wheat was the main cash crop, but by 1850 dairying had advanced to first place. The amount of land cultivated reached its peak in 1880 after which much marginal land was allowed to revert to brush, forest or pasture.

The number of farms fell from about 160,000 in 1930 to 80,000 in a generation (35 yrs.); these farms comprised about 14,000,000 ac. During the same period the average size of farms rose from 112 ac. to about 150 ac. and the value per farm from $6,180 to more than $20,000.

Dairying is by far the most important source of farm income, providing about one-half of the total. Other important sources of farm income are poultry and eggs, livestock products, fruit, vegetables and field crops. The state raises a variety of horticultural specialties including nursery products, crops grown under glass, flower bulbs and seed and competes with Vermont in the production of maple sugar. The fruit and vegetable farms supply the large food-processing industry with such products as apples, cherries, peaches, currants, berries, tomatoes, peas, beans, sweet corn and cabbage.

Manufacturing.—In New York manufacturing developed slowly as artisans in small shops took care of most local needs. Workingmen, in colonial days, belonged to one of four groups: free labour, apprentices, indentured servants and slaves. Bound labour gradually declined since it was less efficient than free labour.

By 1840 New York city won top rank among the cities of the nation in manufacturing. A chain of commercial and manufacturing centres grew up along the Erie canal and New York Central railway. The Industrial Revolution progressed fairly slowly, however, and as late as 1850 most goods were made by hand in the home or in the shops of craftsmen. The textile industry had started during the War of 1812 when British imports were unobtainable. Small textile factories grew up along the streams of Oneida, Columbia and Dutchess counties. The clothing manufacturers employed the largest number of workers by 1860, with New York city and Rochester as the main centres of the industry. The processing of foodstuffs—brewing, milling, meatpacking—gradually moved from small local establishments that used water power to larger concerns in the cities where coal was the source of power.

New York has ranked first among the states in the value of its manufactures since 1830. The exceptional transportation facilities, the commercial supremacy of New York city, the location of the state near the great trade routes, the influx of millions of immigrants both skilled and unskilled, the ample financial resources and the availability of power were the major factors stimulating the industrial development of the Empire state.

New York's pattern of manufacturing activity has been distinctive in several respects. For decades the nondurable goods industries employed more than 60% of all the state's manufacturing workers, a percentage considerably higher than that for the nation. Since World War II, however, the durable goods industries have grown rapidly offsetting the drop in employment in textiles, clothing and other nondurable goods. Similarly, an unusually large percentage of employed workers were engaged in the service trades. The apparel trades accounted for 21% of all manufacturing employees compared with only 6% for the rest of the United States. The ten leading industries in 1860 were flour, men's clothing, sugar refining, leather, liquors, lumber, printing, boots and shoes, machinery and oil; in 1960 they were apparel, printing and publishing, food, machinery, electrical machinery, chemicals, transportation equipment, instruments, fabricated metal products and primary metals. In 1860 most of the industry was engaged in the processing of the products of farm or forest

but by mid-20th century heavy goods such as machinery, metals and transportation equipment were very important to the economy of New York.

In the second half of the 20th century, New York state led all of the others in the number of persons employed in the apparel, printing and publishing, paper and paper products, instruments and furniture industry groups. The state produced approximately 50% of the country's total output of women's dresses, coats and blouses, 90% of the women's furs and 35% of men's and boys' tailored clothes. It produced about 70% of the value of photo equipment manufactured in the nation. The total value added to manufactures, rising steadily each year, exceeded $19,000,000,000 in the 1960s.

In upstate New York there are six metropolitan areas that are leading industrial centres. They are Buffalo, Rochester, Albany-Troy-Schenectady, Syracuse, Utica-Rome and Binghamton. The Buffalo area has the largest steel-producing plants in the state and great aircraft and chemicals plants. Rochester is famous for its manufacture of cameras and scientific instruments. The state's electrical machinery industry is centred in the Schenectady, Utica and Syracuse areas. Syracuse also is famous for china, chemicals and machinery. The Binghamton region specializes in the manufacture of business machines, photographic supplies and shoes. Also, tremendous industrial expansion has taken place on Long Island since 1945, especially in the making of aircraft and instruments. The construction of the St. Lawrence power project has led to the construction of many new factories particularly aluminum plants.

Minerals.—New York produces more than 30 mineral substances. Among them are cement, iron ore, stone, sand and gravel, coke, clays, gypsum and zinc. Deposits of petroleum and natural gas are found in the southwestern part of the state. New York is a leading producer of salt (about 20% of U.S. total) for domestic, industrial and chemical uses. Minor minerals such as talc, emery, garnet and titanium are mined in the Adirondack region. The state ranks about 18th among the states in the value of its mineral output—more than $200,000,000.

Iron and lead have been mined in New York since colonial days. Troy became a steel-processing centre and steel processed there was used in the construction of the "Monitor" in 1862. Until about 1880 the state remained an important centre of iron mining, but thereafter the industry declined steadily in importance until World War II. Following the war, however, there was an increase in the mining of lead, zinc and titanium. For many years, New York was the only producer among the states of emery and it has been a leader in the production of talc, soapstone and pyrophyllite.

Commerce and Finance.—New York is by far the leading state of the union in wholesale and retail trade and employs over one-fifth of the total persons employed in these occupations. Commerce has been significant to the economy of New York from its earliest history. The export of breadstuffs increased so rapidly that the flour barrel was placed on the official seal of New York city in 1682. Most trade, at that time, consisted of the exchange of foodstuffs and furs for manufactures from England and for sugar and molasses from the West Indies. Shipowners often ignored the navigation acts by trading with the planters in the French and Spanish West Indies. The port of New York became the leader in foreign trade between 1810 and 1820, and by 1840 had achieved unquestioned supremacy. During the next century it controlled roughly one-half of the nation's foreign commerce, measured in terms of value. It ordinarily handled more than half of the nation's imports and over a third of its exports. The rapid expansion of population and industry in the Gulf states and on the Pacific coast since 1920 has gradually reduced New York's relative share of the nation's commerce, but in the second half of the 20th century it still handled 35% of imports and 27% of exports (by value). The three northern customs districts (Buffalo, Rochester and St. Lawrence) handle almost 30% of all United States trade with Canada, the nation's largest customer. One-half of all passengers to and from foreign countries overseas pass through the port of New York.

New York city is the world's financial centre because of its stock exchanges, banks and other financial institutions. Upstate cities also have important financial resources. It has been estimated that about 20% of the total liquid savings in the United States, including time deposits, life insurance equities, savings bonds, saving and loan shares and postal savings are held by residents of New York. New York city banks in the 1960s granted nearly 30% of all commercial and business loans in the United States and handled about three-fourths of the financing of the nation's foreign trade. At the same time, investors transacted on the New York stock exchange and the American stock exchange 93% (based on value) of all security transactions reported on all exchanges. More than 20 life insurance companies, including three of the first four in assets, have their headquarters in New York city. The city also dominates the marine-insurance field.

Transportation.—New York has one of the finest harbours on the North Atlantic coast, the best route through the Appalachian barrier and an excellent system of waterways, both natural and man-made. The success of the Erie canal, opened in 1825, led to the construction of several lateral canals and the enlargement of the Erie between 1836 and 1862. The steam railways, however, began to challenge the canal especially after 1850. The first railroads began operations about 1831. During the 1850s the eight short lines across the state began to take freight away from the canal. The establishment of the New York Central railroad in 1853 dramatized the fact that the railroads had become large corporations. In 1851 New York city was linked with Greenbush across the Hudson from Albany by the Hudson River railroad and the Harlem railroad, and it was indirectly connected with Lake Erie by the Erie railroad (now the Erie-Lackawanna railroad) which had a line from Piermont on the Hudson to Dunkirk on the lake. Cornelius Vanderbilt got control of the Hudson River railroad and in 1869 took over the New York Central. This system subsequently acquired connections with Chicago, Montreal and Boston, leased the West Shore railroad in 1886 and purchased several feeder lines. Other important railroads in New York were the Lehigh Valley; the Pennsylvania in the central and western part of the state; the Delaware and Hudson; the Boston and Maine in the east; and the Long Island Rail Road. Railroad mileage in 1960 was about 7,000.

Transportation by water, highway and air challenged the supremacy of the railroads in the 20th century. In 1903 the voters approved the construction of a new Barge canal partly because they wanted to punish the railroads for granting lower through rates from Chicago to Philadelphia and Baltimore than from Chicago to New York city. The New York State Barge Canal system, which was not completed until 1918, included 522 mi. of canal with branches to Oswego, Lake Champlain, Seneca lake and Cayuga lake. The Barge canal normally carries about 4,000,000 tons of goods a year, more than half of which are petroleum products. (*See* also ERIE CANAL.) The taxpayers subsidize the canal system since the shippers do not pay tolls.

In the second half of the 20th century New York had about 100,000 mi. of roads which ranged from dirt roads to multilane parkways. In 1948 the state Thruway authority began the construction of a 550-mi. superhighway connecting New York city with Buffalo and the Pennsylvania line. The last link of the thruway from Albany eastward to Massachusetts was opened in 1958. Airlines connect the various cities and the state as a whole with the rest of the country and the world. In the 1960s New York had more than 250 airports, including the huge John F. Kennedy International airport (formerly the New York International airport) at Idlewild on Long Island. *See* also references under "New York" in the Index.

(D. M. El.)

NEW YORK (CITY), the largest city in the U.S., is situated at the mouth of the Hudson river, there sometimes called the North river. The five boroughs comprising the city are: the Bronx (Bronx county), 54.4 sq.mi., on the southernmost part of the mainland adjacent to and below Westchester county and separated from the borough of Manhattan by the Harlem river (a canalized waterway connecting the Hudson and East rivers); Manhattan (New York county), 31.2 sq.mi., on Manhattan Island between the Hudson and East rivers; Queens (Queens county), 126.6 sq.mi., on Long Island adjoining and to the west of Nassau county and separated from the Bronx and Manhattan by the East river; Brooklyn (Kings county), 88.8 sq.mi., adjoining and to the south of Queens at the western end of Long Island; and Richmond (Richmond county), 64.4 sq.mi., on Staten Island in New York bay, southwest of Brooklyn and separated from it by the Narrows (a strait connecting Upper and Lower New York bays) and from the mainland of the state of New Jersey by tidal estuaries known as Kill van Kull and Arthur Kill. The total area of the city is 365.4 sq.mi. The greatest width of the city, from the eastern boundary line of Queens to the western border of Richmond, is 25 mi.; from the same point in Queens to the western end of 23rd street at the Hudson river in Manhattan, is 16.5 mi. The greatest over-all length, north to south, is 36 mi.

The city's more important small islands are: North and South Brother, Rikers, City, Hunter, Hart, Governors (occupied by a U.S. military reservation, Ft. Jay), Welfare (formerly Blackwell's), Ward's, Randall's (latter three occupied by state and city institutions) and numerous islands in Jamaica bay. Liberty Island (name changed from Bedloe's Island June 29, 1960; the site of F. Bartholdi's Statue of Liberty) and Ellis Island, where the federal government formerly maintained the best-known and most active immigration station, are in Upper New York bay, within the bounds of New Jersey.

The total water front within New York city is 578 mi., of which Manhattan has 43 mi.; Brooklyn, 201 mi.; the Bronx, 80 mi.; Queens, 197 mi.; and Richmond, 57 mi. The two flanking rivers, the Hudson and the East, are not true rivers. The former, up to Troy, is a tidal arm or narrow inlet of the sea; the latter, a 16-mi. tidal strait, connects New York bay with Long Island sound.

HISTORY

Discovery and Exploration.—New York bay and the Hudson river were apparently first discovered by Giovanni da Verrazzano, a Florentine navigator, on April 17, 1524. The first conclusive exploration of New York bay and the Hudson river, however, was made by Henry Hudson, an Englishman sailing for the Dutch East India company, in the "Half Moon" during Sept. and Oct. 1609. Unable to reach the orient around the north of Siberia by way of the ice-packed Arctic ocean, instead of returning to Holland Hudson sailed westward and ultimately into New York harbour. Beginning in 1610, Dutch captains such as Adriaen Block, Hendrick Christiaensen and Cornelis Jacobsen May voyaged to Manhattan. The fur trade was the primary attraction. Block explored New York harbour, Long Island sound, the Connecticut river as far as present-day Hartford and discovered Block Island in 1614. On March 27, 1614, the states-general of the Netherlands granted a general charter to 13 shipowners whose five vessels were trading in the New York area; they were required to make four voyages by Jan. 1, 1618; and were given a monopoly of trade in New Netherland. When their charter expired in 1618 the Dutch government declined to renew it. Instead, seeking a western counterpart for their Dutch East India company, the government chartered the Dutch West India company in 1621. This powerful trading corporation was granted a monopoly of trade throughout the western hemisphere.

Dutch Period.—In 1624, 30 Protestant Walloon families were sent by the company to augment the few trading post settlers already there. Only about eight men remained on Manhattan. The next year more colonists came, and when the first director, Cornelis May, was succeeded by director Willem Verhulst in 1625, the colony numbered almost 200 persons. The government of New Netherland province was vested in a director-general and council. These officers, though formally appointed by the company, were subject to the approval of the states-general. The first director-general, Peter Minuit, arrived with additional colonists in 1626, purchased Manhattan Island from the local Algonkian Indians with pieces of bright cloth, beads and other trinkets to the value of 60 guldens, or about $24, erected Ft. Amsterdam at the lower end of the island and changed the name of Manhattan to New Amsterdam and made it the seat of government. Recalled by the company in 1631, Minuit was replaced first by Bastiaen Jansen Krol and then by Wouter van Twiller in March 1633 who in turn remained until March 1638, when he was recalled because of his mismanagement. He was succeeded by Willem Kieft, an Amsterdam merchant, whose Indian policy proved disastrous to the colony. He levied a tax on the Algonkian tribes for the presumed purpose of protecting them from the neighbouring fierce Iroquois, but declined to assist them after the Iroquois attacked. The result was four years of intermittent but savage warfare between the Dutch and Algonkins. Kieft's one great virtue was his tolerance of freedom of worship.

Peter Stuyvesant (*q.v.*), last of the Dutch governors, was appointed in 1646 and administered the colony until the English conquest in 1664. He defied colonists and company alike. Grudgingly, under the company's specific orders, he was compelled to grant the first municipal charter to New Amsterdam on Feb.

1653, but kept the city under such close supervision the new municipal powers were virtually nullified. In view of Stuyvesant's shortcomings and the feeling that they were employees of an indifferent corporation rather than Dutch nationals, it was inevitable that the populace declined to obey the governor and resist the English ultimatum for the surrender of the province. Accordingly, Stuyvesant was compelled to capitulate on Sept. 8, 1664, to Col. Richard Nicolls without the firing of a shot. The English flag was raised over the fort, which was renamed Ft. James, after the new proprietor, James, duke of York, and New Amsterdam became New York.

English Rule.—The rights of the Dutch settlers were carefully maintained at first, and established institutions changed only gradually. The English reorganized the city government (1665) with a mayor, five aldermen and a sheriff to be appointed by the governor of the province for a term of one year, and also extended the city limits to include all of Manhattan Island. The third Anglo-Dutch War broke out in 1672, and on Aug. 8, 1673, New York was recaptured by the Dutch. Capt. Anthony Colve became the governor-general until the treaty of Westminster ended the war in 1674, and Colve turned the city over to Sir Edmund Andros, the new English governor, who restored the English form of city government.

The next century was a continuous struggle for control of the city government between the Tory-supported royal governors and the largely Whig populace. The first serious manifestation of American resistance came with the refusal of the merchants of New York and other parts of the province to pay certain duties exacted by the "duke's laws" which had been promulgated in 1665, and which were essentially a code of laws and a constitution for the newly created county of Yorkshire (Westchester, Long Island and Staten Island). (*See* also NEW YORK [state]: *History.*)

Gov. Thomas Dongan, one of the colony's ablest governors, arrived in 1683 with instructions to call a general provincial assembly for which the colonists had been petitioning. Accordingly, the first general assembly met on Oct. 17, 1683, in Ft. James, consisting of Dongan, 10 councilors and 17 representatives elected by the free citizenry. The new assembly on Dec. 8, 1683, divided the city into six wards, each to choose one alderman and one assistant alderman; these 12, together with the mayor and the recorder (a new judgeship of the mayor's court for trying criminal cases) were to comprise the new common council. All former rights and privileges were confirmed; the city was given eminent domain; it could sue and be sued; it could acquire and grant lands; and it could grant and regulate franchises and rights. Freemen could also elect constables and assessors. All these rights were now legally confirmed by Dongan's formal grant of a municipal charter, the first under English rule, on April 27, 1686. In addition, the charter provided for sources of income for the city and conveyed to it the proprietorship of the city hall, the market houses, bridges, wharves, docks, cemeteries, ferries, unoccupied lands and the waters within the city. The city seal presented to the corporation the same year is that which it now employs except that an eagle was substituted for the royal crown in 1784.

One of the most important occurrences in this period was Leisler's rebellion (1689–91), the local counterpart of the revolution in England which had dethroned James II. Jacob Leisler (*q.v.*), loyal to the new monarchs, William and Mary, seized the local government in their name, and was appointed by the local committee of safety as the equivalent of the first popular governor of New York province. In turn, he obtained the election of Peter de Lanoy as the first popular mayor of the city, a privilege that was to lapse until 1834. William's and Mary's new governor, Col. Henry Sloughter, persuaded by Leisler's foes that he was a traitor, had him and his son-in-law hanged in 1691, the only persons ever hanged in the province or state for treason. In 1695 parliament exonerated them and two years later restored the martyrs' property that had been forfeited by the provincial court.

Governor Sloughter appointed as mayor Abraham DePeyster, who was effective in conciliating the warring factions for the time and responsible for many public improvements. The old "rattle watch" or police of the city was reorganized by DePeyster in 1697 and placed again under civil control. DePeyster built new wharves, provided the first system of poor relief and instituted improvements in sanitation. The incompetence of governors Benjamin Fletcher, Lord Cornbury and Francis Lovelace increased resentment against English government; and appointed mayors, though in the main men of good standing and usually merchants, were so frequently changed that few made noticeable impressions upon municipal affairs. An exception was William Peartree (1703–07), who established the first free grammar school and a school for Negro slaves and also improved the jail and provided a debtors' prison in the city hall. Gov. Robert Hunter (1710–20) was one of the ablest administrators in America. In 1710 he endeavored to settle about 3,000 German Palatines in the Hudson valley to produce naval stores, but the attempt failed. Between April 7–21, 1712, an insurrection of Negroes took place but was promptly suppressed by Hunter. Nine white men were slain and many more wounded; in retaliation, 21 Negroes were convicted and executed, some most barbarously, and many others were imprisoned. Twenty-nine years later, on Feb. 28, 1741, the alleged Negro conspiracy to burn the city was uncovered, and between then and Oct. 22, 1742, 14 Negroes were burned at the stake and 18 were hanged; 71 were transported out of the colony, and 3 whites were also executed. In 1730 New York received the Montgomerie charter from Gov. John Montgomerie which increased the municipal power by enabling the mayor to appoint subordinate officers with the advice and consent of the common council, and permitted the mayor with a majority of the common council to enact or repeal any by-laws or ordinances they saw fit.

Of especial significance was the trial of John Peter Zenger in the New York city hall in Aug. 1735 on the charge of printing libelous statements in his *New York Weekly Journal* about Gov. William S. Cosby. Zenger was acquitted in what proved to be a tremendous victory for freedom of the press.

The Revolution.—By the middle of the 18th century New York city was regarded as the focal point of resistance to the royal authority. Causes of resentment against English rule were soon forthcoming. One was the impressment of New York sailors onto British men-of-war in the harbour of the city. The merchants of the city reacted vigorously in 1764 and 1765 in protest against the Sugar act of 1764. When New York learned of the passage of the Stamp act on April 11, 1765, the citizenry was stunned and indignant. The Stamp Act congress was convened in the city hall from Oct. 7–25, 1765, with 27 delegates from nine colonies. A Declaration of Rights and Grievances, and additional protests, were dispatched to the British government. The Sons of Liberty commenced perhaps the earliest committee of correspondence in New York city in 1765. While the congress was still in session, a British vessel arrived loaded with stamps, but in the face of popular passion the stamps were secretly landed at night and placed in Ft. George for safekeeping. On Nov. 1, 1765, the date of the act's inception, a crowd proceeded to the fort and to Bowling Green, where Lieut. Gov. Cadwallader Colden was hanged in effigy. Mayor John Cruger, Jr., finally induced Colden to turn the stamps over to the city corporation, but the Sons of Liberty and the merchants were firm in their resistance to the enforcement of the Stamp act and it was finally repealed on March 18, 1766.

Rioting between the Sons of Liberty and the British soldiery became an almost daily occurrence. The first serious bloodshed occurred on Aug. 11, 1766, when the Sons of Liberty were erecting a liberty pole; the soldiers charged the citizens with drawn bayonets, wounding several, including their leader Isaac Sears. On Jan. 2, 1769, Gov. Henry Moore dissolved the assembly for failing to co-operate with the provisions of the Quartering act. In Jan. 1770 another liberty pole was cut down by soldiers resulting in the "battle of Golden hill" (John and William streets) on Jan. 19, about six weeks before the Boston Massacre. Several patriots and soldiers were badly wounded, none fatally, but "much blood was spilt." Frays continued in the days following, and finally Mayor Whitehead Hicks issued a proclamation forbidding soldiers to leave their barracks unless accompanied by a noncommissioned officer. Rumours in early 1774 that tea ships were on their way to New York to carry out Lord North's program of taxa-

tion by means of the Tea act of 1773 kept public indignation at high pitch. The "London" arrived in April 1774 and a party of Sons of Liberty boarded it and dumped 18 cases of tea into the harbour. The closure of the port of Boston in punishment for the Boston Tea Party was the signal for the calling of a meeting at Fraunces' tavern and the election of a committee of 51, which issued the call for the first intercolonial congress. The committee of 51 was dissolved with the election of a new committee of observation of 60 to enforce in New York the Nonimportation act of the first Continental Congress.

When the news of Lexington and Concord reached New York on April 23, 1775, a crowd took possession of city hall and seized the munitions stored there; two British ships in the harbour were seized and their cargoes unloaded. The committee of 60 called for the election of a new committee of 100 to arrange for the calling of a war congress of deputies from all New York counties. This provincial congress met in New York and declared its obedience to the Continental Congress. On April 4, 1776, New York was placed under military rule by Gen. Israel Putnam and Washington later moved his headquarters there. On July 12, British Adm. Richard Howe appeared with his fleet in the harbour, but it was not until Aug. 22 that British troops were landed at Gravesend bay. On Aug. 27 the British took Brooklyn heights. Washington withdrew his troops from Long Island (*q.v.*) and reorganized in New York on Aug. 29. The British then landed at Kips bay on Sept. 15, threw the Americans back and next endeavoured to cut off the American army by throwing a line of troops across Manhattan at about present-day 34th street. The Americans slipped through to Harlem heights, where Washington again reorganized. On Sept. 16 the British attacked unsuccessfully at Harlem heights. On Sept. 21 a fire broke out near Whitehall slip and almost completely destroyed the lower part of the city. Trinity church was burned but St. Paul's and King's college were saved by a shifting of the wind. The following day Nathan Hale, a young spy for the American army who had been condemned by Gen. William Howe, was hanged at a spot near present-day 45th street and First avenue.

New York was held by the British troops for the remainder of the war. It was used largely as a prison camp, and as a gathering place for loyalists (Tories). Churches, warehouses, jails and stores were packed with men sick and well. On the site of the fire, a village of huts and tents had sprung up which was called "Canvas Town." A second disastrous fire on Aug. 3, 1778, destroyed another 60 houses and many stores. Robberies were a daily occurrence and citizens could expect no help from the British soldiers. In Wallabout bay, on the East river, an old hulk, the "Jersey," was used by the British as a prison ship and there more than 11,000 men died. The city was in desperate straits for want of supplies, and sickness ravaged the people. There was no government except military rule and the oppression of civilians by the soldiery was the cause of frequent riots. The revenues of the city were appropriated by the military for their private uses. After the surrender of Lord Cornwallis at Yorktown, Sir Guy Carleton succeeded the intolerant Sir Henry Clinton in May 1782 and immediately undertook the restoration of law and order. By the time of the British evacuation, Nov. 25, 1783, confidence in British government had partially returned.

Formative Years.—The parting of Washington from his troops came on Dec. 4, 1783, at Fraunces' tavern. After the departure of Washington on Jan. 21, 1784, the state legislature began its sessions in New York's city hall, and the city remained the state capital until 1797, when it was permanently removed to Albany. From 1785 to 1790 the federal congress also met in the city hall, and thus the city was for a time both the national and state capital. James Duane was appointed by Gov. George Clinton the first American mayor of New York on Feb. 5, 1784; on Feb. 22 the "Empress of China," sailing from New York, was the first American vessel to enter Asiatic waters; on March 15 the second bank in the U.S., the Bank of New York, was organized with Alexander Hamilton as one of its directors, and on May 15, by act of legislature, King's college became the state university and its name was changed to Columbia college. Several events foreshadowed the important shape of things to come in the city: in 1786 the city's population was 23,614; on June 15, 1787, the Mutual Assurance Co., the city's first fire insurance company, was organized; on Oct. 27, 1787, the first number of the *Federalist Papers* appeared, an effort sponsored by Hamilton and John Jay, both New Yorkers, and James Madison, to ensure the ratification of the constitution by the state; and in 1789 the Tammany society was founded.

On April 30, 1789, Washington was inaugurated president at Federal hall at the corner of Broad and Wall streets. The rise of commerce and wealth drew many people to New York and it began to take on the appearance of a metropolis. Washington made his last official visit to Federal hall on Aug. 12, 1790, and then went to the new capital, Philadelphia. New streets and public utilities were laid out. Bellevue hospital, originally established as the Alms house in 1736, was located on its present site in 1794 for the treatment of contagious diseases. Collect pond, later the site of the Tombs (city prison), was the scene of the first trials of John Fitch's steamboat in 1796. The New York Historical society was founded in 1804. With the help of De Witt Clinton, who served as mayor for ten years between 1803 and 1815, there was organized, in 1805, the Society for Establishing a Free School in the City of New York. Under Clinton, schools were built and Columbia college improved, philanthropic organizations increased in number and arts and letters were stimulated. In 1807 there were 19 newspapers, of which 8 were dailies. Although the Embargo act of 1807 struck New York trade a serious blow, it was not without benefit in stimulating domestic industries. The new city hall was completed in 1812, and there was at this time a considerable advance both in architecture and building construction. Many new buildings, including churches, were built, new streets were graded and swamps filled in along the water front. Collect pond was filled in and the hills and valleys of lower Manhattan were rapidly leveled for homes and other structures.

In the midst of this prosperity, war was declared against Great Britain on June 18, 1812. The commerce of the city suffered from blockade, and the city was put in a posture of strong defense, with additional forts built. On Feb. 11, 1815, the ship "Favorite" arrived in New York under a flag of truce with British and American messengers and the peace treaty of Ghent. Under Mayor Jacob Radcliff (1815–17), the common council appropriated $1,000 for free vaccination against smallpox, which periodically ravaged the city. Mayor Cadwallader D. Colden (1818–21) likewise advanced governmental and private services for public welfare. By 1820 the city's population had reached 123,700, for great numbers of immigrants from Europe were arriving. The problems of dealing with this influx of newcomers were taxing the city and its facilities to the limit. Yellow fever broke out in 1819, 1822 and 1823, and hundreds died daily; another epidemic occurred ten years later and smallpox and malaria also took their toll. Yet, the city continued to grow. The opening of the Erie canal on Nov. 4, 1825, ushered in an even more important phase of New York's commercial history.

By 1830 the population of Manhattan Island was 202,589; mass transportation became a problem only partly solved by the horse-drawn stages and the later horse cars. On Dec. 16, 1835, the "great fire" broke out and destroyed nearly 700 buildings in the heart of the city and virtually wiped out the last vestiges of the old Dutch city that had survived the fires of 1776 and 1778. Croton water was furnished the city on July 4, 1842. Blackwell's (now Welfare) Island, purchased in 1828 for $50,000, was made the site of the city's correctional institutions and hospitals. The *New York Sun* was begun in 1833 by Benjamin H. Day. The *Herald* of James Gordon Bennett appeared in 1835, the *Tribune* of Horace Greeley in 1841 and Henry J. Raymond's *Times* in 1851. On May 7, 1847, the state legislature authorized the city's board of education to charter a free academy, and the academy (later the College of the City of New York; now the City University of New York) was established at Lexington avenue and 23rd street in Jan. 1849. Beyond Union square, which was a residential centre, there was little but open fields at the middle of the 19th century. The World's fair at the Crystal palace on Murray hill was the outstanding event of 1853; in 1856 Central park was purchased. The panic and depression of 1857 paralyzed business

thousands were without employment, more than 900 merchants failed and riots and disturbances of all kinds ensued.

The Civil War Years.—That same year the state legislature actively stepped into the political picture in New York city. Mayor Fernando Wood (1855–58; 1860–62), in the manner of Aaron Burr, had converted Tammany Hall from a political organization into a personal political machine. To weaken his control, the Republicans at Albany reduced his second term from two years to one, and created a metropolitan police board to take over the control of the city's police from Wood's municipal police board. Wood resisted the enforcement of these and other acts and precipitated a riot. Just before the outbreak of the American Civil War, in his message of Jan. 6, 1861, to the common council, Mayor Wood, opposed to the war and a leader of the Copperheads (*q.v.*), favoured the establishment of New York city as a separate state. It was in New York that Abraham Lincoln strengthened his claim to the Republican nomination in 1860 by his Cooper Union speech on Feb. 27 of that year.

With the coming of the Civil War, the city, recovered from the financial panic of 1857, boomed by supplying military needs. It authorized a loan of $1,000,000 for the defense of the Union, and hundreds of thousands of dollars more were privately pledged. New York was again filled with soldiers. On April 19, 1861, its 7th regiment entrained for Washington, and a week later a mass meeting in Union square pledged loyalty to the Union cause. George Opdyke defeated Wood in the election for mayor. The city's war effort was marred by the draft riots of July 13–16, 1863, a protest against conscription and the $300 bounty system for obtaining substitutes. More than 1,000 persons were killed or wounded and property damage exceeded $1,000,000. Mayor Opdyke reported in 1863 that the people of New York had contributed up to that time $300,000,000 for war purposes and had furnished more than 80,000 men to the Union army.

The Brooklyn bridge was begun in 1870, and sanitary conditions, which in 1865 had been thoroughly studied by a citizens' committee and found to be deplorable, were on their way to betterment. The old volunteer fire department was replaced in 1865 by a Metropolitan Fire district that included both New York and Brooklyn, and which possessed a paid, uniformed and trained force. In May 1867 the first tenement house law was passed to regulate the growing number of tenements. The American Museum of Natural History was incorporated in 1869 and in that same year the Metropolitan Museum of Art and the future Hunter college were founded.

Boss Rule And Corruption.—At this time the urban political machine appeared, led by the "boss." The chief prototype of this leader was "Boss" William Marcy Tweed (*q.v.*), who by 1868, as master of Tammany Hall, had manipulated control of the city and county of New York, and enjoyed a virtual stranglehold upon the state as well. He had moved John T. Hoffman into the governorship and A. Oakey Hall into the mayoralty. Together with other officials, these constituted the "Tweed ring." The ring stole from between $75,000,000 to $200,000,000 during its time of power. Ultimately, the disclosures of this graft by the *New York Times* in 1871, the biting cartoons of Thomas Nast in *Harper's Weekly* and the unrelenting campaign of the reform-minded committee of 70 brought about the downfall of the Tweed ring and the imprisonment of some of its members, including Tweed who died in prison in 1878. The next Tammany chieftain was "Boss" John Kelly (1874–86), who fought against political reform.

In 1874 the corporate limits of the city were extended to include about 13,000 ac. across the Harlem river taken from Westchester county and formed into the lower Bronx; and on June 6, 1895, the state legislature further annexed about 20,000 ac. including several incorporated villages in Westchester, thereby rounding out the present boundaries of the Bronx. Following Kelly as leader of Tammany was Richard Croker (1886–1902). Reform movements and investigations complicated his regime and in 1894 William L. Strong became Republican mayor and headed a reform administration. Col. George Waring was made commissioner of street cleaning and inaugurated the modern system of street cleaning and refuse collection. Theodore Roosevelt made an enviable reputation as a member of the board of police commissioners. On Jan. 1, 1898, Greater New York city came into being by a charter passed by the state legislature and plebiscites by the communities absorbed. Kings, Richmond and parts of Queens counties were annexed to Manhattan and the Bronx. Croker had led Tammany to a Democratic victory in a bitter four-cornered mayoralty campaign in 1897 and thus the first mayor of the enlarged city was his candidate Robert A. Van Wyck. The Republican party has failed to win a single mayoralty campaign in the greater city's history. Tammany's defeats have been by fusion movements combining reform, anti-Tammany organizations and sometimes the Republicans. Thus, in 1901, Seth Low, fusion candidate, defeated Tammany's Edward M. Shepard because of investigations disclosing Tammany graft and complicity in police corruption. In 1903, Low, however, was defeated by George B. McClellan, Jr., Tammany's candidate.

Tammany and Reform Movements.—Tammany was in power for approximately 18 out of the next 30 years, and between 1902 and 1924 was led by "Boss" Charles Francis Murphy, whose skill permitted him to survive many defeats that would have deposed a lesser leader. He persisted despite a falling out with Mayor McClellan during the latter's second administration (1905–09); he was repudiated by Mayor William J. Gaynor (1910–13); and he was badly shaken by the victory of perhaps the most able of the city's mayors, John Purroy Mitchel (1914–17).

In McClellan's second term Mitchel had been appointed special investigator after a citizens' civic group published a report on irregularities in the administration of the offices of borough President John F. Ahearn of Manhattan and borough President Lewis F. Haffen of the Bronx. Mitchel secured sufficient evidence of these irregularities to warrant Gov. Charles Evans Hughes's removal of both Ahearn and Haffen. In 1912 District Attorney Charles S. Whitman's exposure of police corruption under Mayor Gaynor helped to make Whitman governor in 1915; Gaynor, wounded in an attempt upon his life, died Sept. 10, 1913. The police scandals during Gaynor's administration, although not of his making, swung popular sympathy against Tammany, and Mitchel, candidate for mayor on a fusion ticket, was elected in 1913. In Sept. 1914 a special aldermanic committee of investigation undertook a complete survey of police administration and methods. The facts finally disclosed furnished clear evidence of police incompetency and corruption. Mayor Mitchel's administration was regarded as exceptionally efficient because of the administrative reforms which he instituted.

In the election of 1917 Mitchel was defeated by an overwhelming vote in a four-candidate race, mainly by the combined forces of Murphy, William Randolph Hearst and "Boss" John H. McCooey of Brooklyn. The victor was John F. Hylan, who held office for two terms (1918–25). Hylan was refused party support for a third term. The Tammany leaders selected James J. Walker in 1925. Walker defeated the Republican candidate, Frank D. Waterman. The great issues of the Hylan administration—rapid transit and subway fares—continued paramount under Walker. In 1932 Walker was summoned before Gov. Franklin D. Roosevelt to answer charges of graft brought by Samuel Seabury, counsel for the Hofstadter legislative committee, and, failing to halt proceedings for his removal, resigned Sept. 1, 1932. After an interim under president of the board of aldermen Joseph V. McKee (Sept. 1–Dec. 31, 1932), surrogate John P. O'Brien succeeded in a special election to fill Walker's unexpired term throughout the year 1933.

The combination of the Seabury disclosures of widespread Tammany graft and corruption throughout the city government and the serious financial difficulties of the municipality put Fiorello H. LaGuardia into city hall as the fusion victor in the election of 1933. He won re-elections in 1937 and 1941. The LaGuardia administration was noted for the unification of the transportation system under municipal operation; the completion of the Triborough bridge and the Lincoln and Queens Midtown tunnels; the development of the Delaware water supply system; and the World's fair of 1939 and 1940. The wave of civic regeneration begun by the Seabury investigations was carried on by District Attorney

THE SOUTH, THE HUDSON RIVER ON THE WEST, CENTRAL PARK ON THE NORTH AND THE EAST RIVER

Thomas E. Dewey and his staff, and by John H. Amen, with a series of political and gangster prosecutions and convictions.

LaGuardia did not run for re-election in 1945, and William O'Dwyer, a Democrat, was elected mayor. The notable achievements of his administration included an extensive building program, with emphasis on schools, hospitals, traffic speedways and public housing. The mayor also instituted a far-reaching program of administrative reform, creating the division of analysis in the bureau of the budget; corresponding methods analysis units in 24 of the major city departments; and the mayor's committee on management survey.

Among the major political issues of the period were the abolition by popular referendum in 1947 of proportional representation as a means of electing the 25 city councilmen and the consequent reduction of the opposition and reform element of the council to a minority of one. Other notable political decisions involved the adoption of a ten-cent fare for the transit system (July 1948), the acceptance of collective bargaining with the subway unions, the refusal to deal with so-called Communist unions, the transfer of the city's airports to the Port of New York authority on a 50-year lease and the sharp increase in salary rates for the top elected officers.

O'Dwyer was re-elected in 1949, but resigned on Sept. 1, 1950, to accept the assignment of U.S. ambassador to Mexico. After his departure the reputation of his administration suffered with the conviction of James J. Moran, former first deputy fire commissioner, for income tax evasion, perjury, conspiracy and extortion. In Nov. 1950 Vincent R. Impellitteri, a Democrat running on the independent Experience party ticket, handed Tammany (now known officially as the New York County Democratic committee) a setback by his surprising defeat of its candidate, Ferdinand Pecora, in a special election to fill the vacancy resulting from O'Dwyer's resignation. Instead of building up the Experience party into an anti-Tammany organization the mayor tried to wrest control of the regular organization from its leader Carmine de Sapio, but without success.

Impellitteri did not run for re-election in 1953 and Robert F. Wagner, Jr., was nominated as the Democratic candidate. Wagner defeated both Rudolph Halley and Harold Riegelman in the election. Four years later, Wagner went on to defeat Robert K. Christenberry, the Republican candidate, and he was elected for a third term in 1961. Among Mayor Wagner's achievements were the completion of the removal of the elevated transit lines from Manhattan; the opening of the great exhibition hall, the Coliseum; the renovation of city hall; and the start of the great Lincoln Square cultural and art centre. A world's fair was opened in New York city in 1964.

POPULATION CHARACTERISTICS

New York had fewer than 200 inhabitants in 1625, and about 1,000 in 1656 and about 16,200 in 1755. Around 1783 New York began its rapid growth as the leading port of the nation. The first federal census in 1790 showed the city's population at 33,131; by 1796, the population nearly doubled over 1786; in 1850, it was 515,394; in 1870, the first post-Civil War census indicated a population of 942,292; and, in 1890, the figure had risen to 1,441,216. In 1898 the present five boroughs were united by the state to form the city of Greater New York and its total population in 1900 was 3,437,202. In 1950 the figure was 7,891,957. The 1960 population was 7,781,984 and divided as follows: Manhattan, 1,698,281; Bronx, 1,424,815; Brooklyn, 2,627,319; Queens, 1,809,578; and Richmond, 221,991. The New York standard metropolitan statistical area (New York city and Nassau, Rockland, Suffolk and Westchester counties) had a population of 10,694,633 in 1960.

Almost every national and racial group in the world is represented among the inhabitants of the city. The location of the United Nations in the city adds a diplomatic cosmopolitanism comparable to the ethnic diversity.

The Negro population in 1960 was 1,087,931, constituting the largest Negro community in the country, and representing a gain of 45.5% over the 1950 figure of 747,608. Negroes between World Wars I and II had increasingly made Manhattan's Harlem their centre, both residentially and culturally, bounded generally between 110th street on the south and 155th street on the north, Third avenue on the east and Amsterdam avenue on the west. The increase of their population and migration from the south after 1940, coupled with the sharp influx of Puerto Rican immigrants into the east Harlem and Bronx areas, led to the expansion of the original Harlem area and encouraged Negro movement into other neighbourhoods in other boroughs with formerly small Negro populations. Negro population by boroughs, as of 1960 was: Bronx, 163,896; Manhattan, 397,101; Brooklyn, 371,405; Queens, 145,855; and Richmond, 9,674.

Puerto Rican immigrants constitute the city's newest marginal economic and social group. The Chinese quarter is in the neighbourhood of Chatham square, on Mott, Pell and Doyers streets. The city of New York has the largest Jewish population of any city in the world.

The foreign-born population, as revealed by the 1960 census, was distributed by native language as follows:

Foreign-Born Population as of 1960 Census

Mother tongue of foreign-born population	Total	Bronx	Brooklyn	Manhattan	Queens	Richmond
English	237,918	53,541	60,344	68,102	51,299	4,632

Source. U S Department of Commerce, Bureau of the Census, 1960 Census of Population.

The population decline in Manhattan accentuates the continuing application of choice Manhattan real estate to skyscraper and other commercial, office and service usage and the fact that the island is increasingly becoming an area of extremes, of either very high-rental units or low-income and slum units. Manhattan is increasingly the borough of employment and livelihood for millions from the outside. Urban renewal has been unable to keep pace with slum blight.

The Bronx and Brooklyn do not reflect the extremes and pressures of Manhattan, but a slight exodus already was apparent in their demographic data, accelerated to some degree by the uncontainable population thrust of the Negro and Puerto Rican families. This is less true of Queens. That borough's continued progress makes it one of the fastest growing counties in the nation, because of realty development within an area greater by far than that of any of its sister boroughs, together with a growing native birth rate and in-migration by all strata of the economic spectrum. Staten Island, also growing slightly in numbers, has room to accommodate a great population increase.

The New York-Northeastern New Jersey standard consolidated area includes the New York, Jersey City, Newark and Paterson-Clifton-Passaic standard metropolitan statistical areas and the New Jersey counties of Middlesex and Somerset for a total of 17 counties in New York and eastern New Jersey. This area had a 1960 population of 14,759,429. In addition to New York city it includes such important centres of industry and population as Newark, Paterson, Elizabeth, Bayonne, Hoboken, Passaic, Union City, East Orange, Perth Amboy, Orange and New Brunswick in New Jersey; and Yonkers, Mount Vernon, New Rochelle and White Plains in New York. For comparative population figures for New York city *see* table in NEW YORK (state): *Population*.

GOVERNMENT AND SERVICES

Administrative Organization.—The city's basic form of government was inaugurated by the charter passed by the state legislature that created Greater New York on Jan. 1, 1898. It provided for a mayor elected at large, 5 borough presidents, a board of aldermen of 65 elected members with a president elected at large. A comptroller, elected at large, was head of the department of finance.

A new city charter providing generally for a strong mayor-council type of government was adopted by popular referendum on Nov. 3, 1936, and became effective on Jan. 1, 1938. It provided for a 25-member city council, elected by a system of proportional representation. This system of election was abolished by popular referendum in 1947 and, under a new law, councilmen were elected by simple majority vote with one from each of the state senatorial districts wholly within the city.

On Nov. 7, 1961, New York city voters overwhelmingly approved adoption of another new city charter, providing for the first major reorganization of the city government since 1936. The new charter, effective on Jan. 1, 1963, was designed to increase the executive power of the mayor; to invest the city council with sole legislative power, subject to the mayor's veto; to deprive the board of estimate of its legislating authority and confine it to passing, along with the council, on the mayor's expense and capital budgets and in approving or disapproving major mayoral changes in the budget during the fiscal year; to transfer from the comptroller to the mayor the power to make the final estimate of general fund revenues for budget-making purposes; to convert the expense budget from a line-item to a program budget; to transfer highway and sewer work from the control of borough presidents to city departments; and to eliminate local assessments for local improvements.

The city council was also made more representative by voter approval of a second question providing that in the election of 10 additional councilmen-at-large, each party or independent group may nominate only one candidate in each of the five boroughs and that voters may vote for only one of them, the two candidates receiving the highest votes to be declared the victors; thus, increased minority representation was guaranteed. The first such councilmen-at-large were elected in November 1963, 5 Democrats and 5 Republicans.

The city council may pass a law over the mayor's veto by a two-thirds vote within thirty days; it may reduce or increase the budget but the mayor has the power to veto any changes; and it may call for an investigation of the conduct and administration of any city department or agency or of any county within the city. Besides the 10 new borough-wide councilmen, the original 25 councilmen are divided as follows: 9 from Brooklyn, 6 from Manhattan, 5 from Queens, 4 from the Bronx and 1 from Richmond. All councilmen are elected for four-year terms.

The board of estimate may add to or subtract from the budget, subject also to the veto of the mayor. The board retains control over zoning, franchises, pier leases, and the leasing and assignment of property; continues as head of the New York city employees' retirement system; and makes recommendations to the mayor or the council on matters of city policy. No franchise granted by the board may be for more than 25 years, except a tunnel-railroad franchise, which may not exceed 50 years. The board is a nonelective body; its membership consists of the mayor, the comptroller and the president of the city council, who each may cast four votes; and the five borough presidents, who each may cast two votes.

With an even stronger mayor-council type of government, the mayor became the responsible directing head of the city. He is the chairman of the board of estimate, recommends legislation, and appoints and may dismiss the city administrator, the city construction co-ordinator, the corporation counsel, the commissioner of investigation and the director of the bureau of the budget. He can organize and reorganize the executive office of the mayor and the city departments. Thus, he appoints the commissioners or executive heads of the police, fire, health, hospitals, welfare, correction, sanitation, public works, markets and 18 other municipal departments, of 16 boards and commissions and of 3 agencies operating from his offices, as well as many lesser officials.

Civil service regulations apply to all officers and employees of the city except to those who are elected, to legislative officers and to staffs of those educational institutions which have special professional standards. In 1920 the city employees' retirement system was put into effect. All persons in city service became eligible for the benefits of this retirement system, except those entitled to share in the police pension fund, the fire department relief fund, the teachers' retirement system or the department of street cleaning relief and pension fund.

An amendment to the state constitution, approved by the voters in Dec. 1935, provided for a reform of the county government within the city of New York. There are five county governments within Greater New York, namely, New York, Bronx, Kings, Queens and Richmond. The officers of the five different counties function almost independently of the city officers. Under the amendment the city has the theoretical power through the enactment of local laws to abolish any county office within its limits except that of judge, county clerk or district attorney; or it may reassign the functions of county officers, with certain exceptions, to city or other county officials or to the courts. The county clerks are appointed and removable by the appellate division of the supreme court in the judicial department in which their respective counties are located.

Finance and Taxation.—The annual expense budget of New York city in the second half of the 20th century amounted to more than $2,000,000,000 or nearly double the amount ten years previously. Approximately 18% was allocated to education; 12% to welfare; 7% to police protection; 7% to hospitals; 4% to fire protection; 4% to sanitation; 17% to debt service; 9% to pensions; and 22% was allocated to all other purposes. To meet this expense budget, the city received revenues as follows: approximately 45% from real estate taxes; 34% from the general fund; and 21% from other funds. The general fund included sales taxes, general business and financial taxes, other special taxes, water charges and other charges, local assistance from the state and "carry-over" funds. Grouped under "other funds" were state aid, federal aid, sewer charges, parking meter revenue and all other sources. Since the nation's beginnings, New York city has contended that it has been required to supply more revenue for the state's needs proportionately than have other areas of the state, but that generally it has received less benefits, services or aid proportionately. Many of the generally Democratic-controlled city's financial difficulties have been blamed upon the discriminatory treatment by the generally Republican-controlled state legislature. It occasioned more than ordinary interest, therefore, when Republican governor Nelson A. Rockefeller and Democratic mayor Wagner on March 26, 1960, agreed upon a fiscal program whereby the city would gain substantial state aid.

Expenditures for capital improvements are considered separately. The so-called capital budget does not include capital expenditures to be paid for by special assessments. Expenditures for capital improvements are allocated among the board of education; the transit authority; public works; gas, electricity and water supply; docks and piers; health, hospitals and sanitation; the parks, libraries and museums; and other recipients.

The assessed valuation of all taxable real estate in the city in the second half of the 20th century aggregated more than $27,000,000,000. Three independent agencies enjoyed revenues of their own. They were the New York city transit authority, the New York city housing authority and the Triborough Bridge and Tunnel authority.

The comptroller is the chief financial officer of the city government. It is his business to advise the mayor, council, and board of estimate; to approve the disbursement of funds; to estimate annually general fund revenues; to audit the accounts of the city departments and agencies; to install a uniform accounting system for all city funds; and to manage the sale and retirement of the city's securities. Aside from the office of comptroller and the bureau of the budget there is a department of finance, headed by the treasurer (formerly the city chamberlain), appointed by the

mayor. This department includes the bureau of city collections and the bureau of receipts and disbursements. Four agencies handle the tax and licence work of the city: the tax department, the board of assessors, the board of revision of assessments and the department of licences. The financial organization of the city also includes a department of purchase which has sole authority for the purchase of supplies and equipment for all departments and agencies of the city government with the exception of the institutions and offices of the board of higher education and the department of education.

Courts.—The judicial system of the city is composed of the following courts: civil; criminal; a division of the state-wide family court; surrogates (estates of infants and deceased persons); and the small claims courts in each borough for cases involving claims of $100 or less. For changes in the court structure of the state *see* New York (state): *Government.*

Police.—The total police force of the city of New York, including patrolmen, detectives, the safety division, emergency, harbour and helicopter personnel, the youth division including the juvenile aid bureau, and plainclothesmen numbered more than 27,000 in the second half of the 20th century. In addition, there were about 1,200 part-time school crossing guards employed by the city. There were about 90 station houses, more than half of them in Manhattan and Brooklyn. A significant feature of the police department is its academy of training, through which all recruits must pass.

Fire.—A fire commissioner heads the fire department, which in the second half of the 20th century had more than 13,000 employees. Under an intensified campaign of specialized inspection and education two school inspections annually have been the rule since Jan. 1, 1959; there are factory-loft inspections; fire wardens receive fire-prevention instruction, as do building superintendents and school custodians; and a new centralized training school was established on Welfare Island.

Health.—Within the department of health is the board of health which consists of the commissioner and four other members, two of whom must be physicians. The department operates offices, health centres and health stations in each borough.

The board of health is responsible for matters of public health policy and for drafting the city's sanitary code. The department exercises sanitary supervision of food supplies and regulates sanitary conditions in establishments that manufacture, handle or store food or patent medicine products.

In the second half of the 20th century the department has been particularly active in the identification of virus diseases, the control of radiological hazards, case finding campaigns against tuberculosis and diabetes, immunization against poliomyelitis, research into the causes of coronary heart disease, a transport service for premature infants and the development of techniques for the early detection of cancer. The New York City Health Research council was created in 1958. That year marked the 50th anniversary of the founding of the maternal and child health services; in that half-century there was a reduction of 77% in the city's infant mortality rate. A considerable number of voluntary health agencies operate in the city and co-operate with the health department.

Hospitals.—The department of hospitals was established in 1930 by the consolidation of the general and special hospitals of the departments of health and welfare, and Bellevue and allied hospitals. Among the chief private general hospitals are Mount Sinai, St. Luke's, Presbyterian, New York, Roosevelt, Lenox Hill and Post Graduate, all in Manhattan. In the Bronx are the Montefiore and Misericordia hospitals. In Brooklyn are the Long Island college hospital, Jewish, Brooklyn and Methodist Episcopal hospitals. Of the private special hospitals for women and children, the Lying-in, Sloane Maternity and Woman's are the largest. Other special hospitals of note are the Joint Diseases, Special Surgery, New York Eye and Ear infirmary, Manhattan Eye, Ear and Throat hospital, Skin and Cancer clinic and Neurological institute. The larger municipal hospitals, each providing 1,000 beds or more, are Bellevue, Kings county, City, Metropolitan, Sea View and Triboro.

Among the events of interest in connection with the private hospital services of the city have been the establishment of the Columbia-Presbyterian Medical centre and the New York Hospital-Cornell Medical centre. In upper Manhattan are clustered the buildings of five separate units: the Presbyterian hospital (including the Presbyterian hospital, the Sloane hospital for women, the Vanderbilt clinic, the Squier urological clinic, the Stephen V. Harkness private patient pavilion and the Presbyterian hospital school of nursing); the Columbia university group (including the college of physicians and surgeons, the school of dental and oral surgery, the school of oral hygiene and the DeLamar Institute of Public Health); the Babies' Hospital of the City of New York; the Neurological Institute of New York; and the New York State Psychiatric institute and hospital. The New York Hospital-Cornell Medical centre includes the New York hospital, the Payne Whitney Psychiatric clinic, the New York Hospital-Westchester division for mental diseases at White Plains, N.Y., the Cornell University-New York hospital school of nursing and the Cornell university medical college.

Public Assistance.—The objectives of the department of welfare are to grant financial aid to those in need who are eligible to receive it, and also to return recipients and their families to self-support as soon as possible. The forms of public aid from city, state and federal funds administered by the department are: home relief; veteran assistance; old-age assistance; blind assistance; aid to dependent children; aid to the disabled; shelter care; child welfare; day care; custodial care; and hospitalization.

In 1941 the work of various independent city agencies were made a part of the larger central welfare agency. The private relief agencies of the city offer a great variety of services for family welfare and institutional care. The more important ones are affiliated with the Welfare council of New York city, which seeks to co-ordinate the efforts of the individual agencies and carries on special research and informational services in the interest of all agencies and the general public. Mention should be made also of the Jewish Board of Guardians, the many Catholic charities and the Community Service society of New York. The latter was formed by the merger in 1939 of the Association for Improving the Condition of the Poor (1848) and the Charity Organization society (1883).

Correction.—The department of correction has a threefold goal: to relieve acute overcrowding in all penal institutions as a result of the steady increase in the number of prisoners since World War II; to close obsolete prison buildings; and to separate inmates properly in order to promote rehabilitation and academic and vocational training. The department administers the city institutions for the care and custody of criminals and misdemeanants and for the detention of persons awaiting trial. In 19[illegible] the correction academy was established to provide essential training for the department's personnel. In 1958 an agreement was reached whereby self-committed narcotics addicts would no longer be dealt with as prisoners, but as patients to be cared for by the department of hospitals. Apart from the department of correction, the city magistrates' courts, the courts of domestic relations, the courts of special sessions and the county courts provide an extensive system of probational investigation and supervision. There is also a city parole commission whose jurisdiction extends to prisoners given indeterminate sentences by the city courts and the parole officer assigned to each offender retains supervision for three years. A large number of private agencies also deal with correctional problems.

Public Water Supply.—In the early years, the water supply of New York was derived from wells, streams and ponds. In 1[illegible] the Manhattan company was incorporated ostensibly to supply the city with water but, under a clause in its charter, devoted itself primarily to the banking business. In 1834 the legislature authorized the city to begin the necessary works to bring water from the Croton watershed more than 30 mi. N., and the first Croton water was delivered to the city in 1842 through the Croton aqueduct. In 1883 a new Croton aqueduct was authorized and thus additional water became available in 1890. In 1905 the board of water supply was created and work was begun on a new system to bring

water from the Catskill mountains, more than 100 mi. N. This commission developed an additional water supply from the Esopus and Schoharie watersheds with a total dependable yield of about 500,000,000 gal. daily flowing through the Catskill aqueduct which delivers its water just north of the city line into Hill View reservoir in Yonkers, having a storage capacity of 900,000,000 gal. A new construction program to draw water from the Delaware river, begun in 1936, was planned by the board in three stages. The first stage, comprising the Rondout and Neversink reservoirs and the Delaware aqueduct, began contributing to the city's water supply in 1944. The second stage began to contribute its water in 1955. The third stage of the Delaware system commonly is known as the Cannonsville project. The three stages together were planned to yield an additional 920,000,000 gal. daily. A drainage area of 1,700 sq.mi., greater than the entire land area of Rhode Island, is required for the city's water-supply system.

Sanitation.—A department of sanitation was created in 1929, consolidating five separate borough departments into one division of street cleaning. In 1933 the three-member sanitation commission was replaced by a single commissioner. In Oct. 1955 the city undertook its largest crusade against litter. In 1958 a related drive against "litterbugs" was begun which used both education of the public and a rigorous enforcement of the sanitary code. The department, aided by other departments and agencies, summoned violators.

Public Works.—The department of public works also is directed by a commissioner. The department has charge and control of planning, construction and repair work of all structures, buildings and other public works paid for wholly or in part by city funds and is charged with maintaining and operating them. It also has charge of sewers and sewage-disposal plants. Under its jurisdiction are public buildings of every description, including city hall, bridges, court buildings, hospitals, health centres, parking facilities and libraries. The city has been engaged in a vast sewage-disposal program to eliminate the pollution of its harbours for many years. An engineering bureau was established in 1930 to tackle this problem and in 1938, under the new charter, it came under the department of public works. The early bureau commenced work on the Ward's Island plant, and completed the Coney Island plant, giving the city its first modern sewage-disposal plant in 1935. Within five years three additional plants had been completed and put into operation: Ward's Island plant, Tallmans Island plant and a part of the Bowery bay plant. In 1948 this program was given additional impetus when the Interstate Sanitation commission stipulated that all sewage pollution of waters within its jurisdiction should end by Dec. 1959. The department has undertaken a refuse-disposal program in conjunction with the sanitation department which involves the construction of new incinerators, new marine transfer stations, marine unloading stations, the modernization of older incinerators and the improvement of transfer stations.

Postal Services.—The post office of New York city in 1827 was located in a small two-story frame building on Garden street (now Exchange place) and the entire force consisted of about eight clerks and six letter carriers. In 1869 the city hall post office at Park row and Broadway was the main post office. It was razed in 1939. In 1914 a new general post office building was opened on Eighth avenue from 31st to 33rd streets, containing 500,000 sq.ft. of floor space. The transportation of mails is expedited by means of an underground pneumatic-tube system consisting of 27 mi. of double-line eight-inch tubes with a carrying capacity of approximately 200,000 pieces of mail per hour.

City Planning and Zoning.—The Greater New York charter adopted in 1898 provided that the responsibility for laying out street systems should be primarily vested in the borough presidents, with specific approval resting on the board of estimate and apportionment and independent approval by the mayor for changes in plan. In 1903 the board of aldermen created an improvement commission; in 1913 a heights-of-buildings commission was created. The latter led to the building zone resolution of 1916 which regulated the height and bulk of buildings thereafter erected and the boundaries for trades and industries. The charter adopted in 1936 provided for a city planning commission. This body was charged with the preparation of a master plan for the future development of the city. It is responsible for completing and maintaining the city map; zoning changes; the preparation of a capital budget and a five-year capital improvement program; the approval of assessable improvements; and the selection and acquisition of land for streets and sites for large public improvements. In 1958 the commission initiated plans for urban renewal and in 1960 the stage was set for the final plan for the West Side Urban Renewal project.

Public Markets.—The department of markets supervises and controls public markets, pushcarts, indoor and outdoor street markets and terminal markets to assure adequate distribution of food, purity of content and protection from profiteering and fraud; it issues market and pushcart permits; it supervises the manufacture and sale of ice; it inspects weights, measures and scales; and it provides consumers with price information.

The city's chief wholesale markets are the Bronx terminal, the New York city live-poultry terminal in Queens, the Gansevoort market meat centre, the Peck Slip in Manhattan and the Brooklyn terminal markets. In addition, there are a few pushcart or street markets, a picturesque remainder and feature of the city's congested foreign districts.

COMMERCE AND INDUSTRY

Harbour.—During the second half of the 20th century the port of New York was the busiest in the U.S., averaging more than 25,000 ship arrivals and departures annually. New York's harbour is naturally divided into several parts. At the entrance from the Atlantic is the outer harbour (about 122 sq.mi.), known as Lower bay. Raritan bay lies adjacent to the Lower bay on the west and the Raritan river and the Kill van Kull flow into the west side of Raritan bay. The Ambrose channel is the chief of several channels crossing the broad bar at the entrance to the outer harbour. It leads northwestward and then northward into the inner harbour through the Narrows, a neck about 1 mi. wide between Long Island and Staten Island. The inner harbour consists of the Upper bay, 4 mi. long and 4 mi. wide, the lower Hudson river, the East river, Long Island sound and tributary waterways. Anchorage channel, an extension of Ambrose channel, extending through the Upper bay to the mouth of the Hudson river at the Battery, affords a depth of 40 ft. at mean low water for a width of 2,000 ft. Within the port are 42 channels, from 38 to 45 ft. deep.

The port of New York has a total length of developed frontage measured around piers and shore lines of about 755 mi., with about 460 mi. in New York and 295 mi. in New Jersey. The harbour has two northern entrances: the northeast entrance from Long Island sound by the East river, principally used by New England coasting vessels; and the North (lower Hudson) river, by which the inland water-borne traffic of the Hudson river and Erie canal is brought to the port of New York. There are nearly 400 vessel berths in the port. In the second half of the 20th century the ocean-borne foreign trade passing through the port, in terms of general cargo, was more than 13,000,000 long tons and in terms of bulk cargo, more than 27,000,000 long tons annually.

In 1921 the states of New Jersey and New York adopted the principles under which the Port of New York authority was established; its purpose was to co-ordinate the terminal, transport and other facilities of commerce in and about the port of New York. This agency and the department of marine and aviation operate most of New York city's port facilities. Most of the docks are controlled by the latter; most terminal, transport and other facilities are controlled by the former. The area of the port of New York district within the jurisdiction of the port authority is about 1,500 sq.mi., extending from below Sandy Hook on the south to Tarrytown on the north. The Holland vehicular tunnel, opened in 1927, was brought under the port authority's control in 1930. The Lincoln vehicular tunnel was opened in 1938. (*See* also PORT.)

Banking, Exchange and Insurance.—New York city, the headquarters of major enterprises and of professional, executive

and managerial personnel, is the nation's executive capital. At the same time, it is the financial capital of the world. From the beginning of the city's history, the financial district of New York has been at the end of Manhattan Island, below Fulton street. The largest banks and trust companies, the exchanges and many insurance headquarters are there as are the New York Stock and American Stock exchanges, the Coffee and Sugar exchange, the New York Cocoa exchange, the New York Cotton exchange, the Maritime exchange, the New York Produce exchange and the Commodity exchange. In 1784 Alexander Hamilton wrote the constitution for the Bank of New York, the first to be established in the city and in operation five years before the U.S. constitution was adopted. The first bank of the United States was established in 1791, and a branch known as the office of discount and deposit was opened in New York in the same year. The Bank of the Manhattan company, in which Aaron Burr was interested, was the third bank to be organized in the city and its charter is notable as being the first to enable a public utility company to engage in banking.

The subtreasury of the United States, formerly on Wall street, was abolished in 1914. On Feb. 21, 1940, it became a national monument—Federal Hall memorial. A part of the functions of the subtreasury is carried on by the U.S. assay office at 32 Wall street. The New York clearinghouse, located on Cedar street, was established in 1853. Bank clearings in the second half of the 20th century have been exceeding more than $600,000,000,000 annually. New York is the centre of federal reserve district no. 2. The New York Stock exchange has more than 1,300 members. The American Stock exchange was formerly an open-air market for unlisted securities. It is now housed in its own building at 78 Trinity place, completed in 1921. In Jan. 1953 the exchange took its present name and dropped its former title of New York Curb exchange.

Wholesale Trade.—New York city, the largest wholesale trade centre in the U.S., employs more than 300,000 persons in wholesale establishments. The total wholesale trade conducted amounted to more than $45,000,000,000 annually in the second half of the 20th century.

The clothing industry is chiefly centred in Manhattan, between Washington square and 42nd street, and in cross streets between Seventh avenue and Broadway. Silk establishments have two principal centres, one bounded roughly by 23rd and 34th streets and Third and Fifth avenues; the other, on or adjacent to Broadway between Canal and Eighth streets. Fur establishments are sharply localized between Broadway and Eighth avenue and 26th and 30th streets. The millinery business has moved to a centre between Broadway and Fifth avenue above 34th street. Boot and shoe establishments are almost exclusively in lower Manhattan between Broadway and West Broadway below Canal street. Jewelry, formerly concentrated in and about Maiden lane, later became distributed in smaller groups between Maiden lane and 50th street along Broadway and Fifth avenue, with large and growing centres at and about the intersection of Canal street and the Bowery and on 47th street between Fifth and Sixth avenues. Fruit and produce markets are centralized in Manhattan between Canal and Cortlandt streets and West Broadway and the North river. The fish, butter, egg and cheese markets are highly concentrated on the lower west side between Harrison and Greenwich streets and meat establishments centre at West 14th street and the North river. The coffee, tea and spice markets are mainly in a small area on the lower east side about Water and Front streets. Hardware houses are west of Broadway, between Houston and Fulton streets; paper and stationery are much more widely scattered than formerly, largely because of the uptown movement of printing and publishing establishments, one great centre being at or near Park row and the other in the neighbourhood of the main post office about 34th street. Drug establishments are chiefly in lower Manhattan, while leather dealers are just below Brooklyn bridge.

Retail Trade.—The retail trade has followed the northward movement of the population. In 1850 it was at Canal street and by 1880 at 14th street. By mid-20th century it was between 31st and 59th streets, and Third and Eighth avenues. Fifth avenue was formerly exclusively residential but later was given up to retail trade as far north as 60th street. Beyond that a zoning ordinance reserved Fifth avenue for residence. Some of the largest department stores are on 34th street and the greatest volume of trade is done there. But the northward trend of the residential section affected the character of the trade, and the more expensive shops, including some of the oldest retail firms, are farther up Fifth avenue. Madison avenue, because of its situation between Park and Fifth avenues, rapidly took on the aspect of the latter, and is lined with shops from 42nd street to 84th street. The art and antique dealers are on 57th and adjacent streets and also on Madison and Lexington avenues. There are a number of small antique shops on Eighth street. Automobile houses are near Columbus circle and up Broadway from 55th street for more than ten blocks. Brooklyn and the Bronx have important shopping and financial districts of their own. The growth and decentralization of population precipitated a trend among large department stores toward building branches of their stores in suburban areas of the city and in many cases in the neighbouring counties. In the second half of the 20th century retail trade establishments had an annual sales volume of more than $9,000,000,000.

Building Construction.—More than half of the city's homes and apartments were less than 50 years old and were built in three great waves of housing construction since 1921. Vast projects, such as Stuyvesant Town, Cooper Village, Parkchester, Fordham Hill and Fresh Meadows, have been constructed with funds supplied by large institutional investors. In addition, two large-scale urban renewal projects for the development of municipally sponsored modern industrial parks to aid industry have been undertaken on former slum sites. From 1958 there has been a marked increase in private-enterprise housing built with the aid of federal, state or city government.

Modern building construction in New York dates from the erection of the ten-story Tower building in 1889. The loftiest building in the world, the Empire State building on Fifth avenue at 34th street, rises to a height of 1,250 ft. from the street level and has 102 stories. Rockefeller Center, the largest privately owned business and amusement centre in the United States, begun in 1931 and completed in 1947 with the addition of a new building to the group completed before World War II, covers almost 13 ac. between Fifth and Sixth avenues from 48th to mid-51st streets. There are 15 separate buildings and the 5 edifices of the western section of the centre comprise Radio City. From the end of World War II, New York city has experienced a phenomenal building boom resulting in nearly 150 new office buildings. Manhattan's midtown area especially has been the centre of this commercial office and skyscraper building renascence, with the downtown area assuming the secondary role. Several commercial offices and skyscrapers built after World War II include: Chase Manhattan (60 stories), Union Carbide and Carbon (52), Time & Life (48), National City Bank (43), Socony Mobil (42), Equitable Life (42), International Telephone and Telegraph (33), Produce Exchange (33) and Pfizer (32).

Laws affecting building in the city date back to 1647 and they dealt primarily with fire prevention. In 1867 a law dealing with fire prevention and ventilation was passed; in 1879 this law was amended so that no new tenement could occupy more than 65% of the lot and there had to be at least 600 cu.ft. of air space per person per room; in 1899 a new building code was adopted; in 1901 a tenement house law was enacted. In 1916 the city's first zoning ordinance was adopted regulating use, height and percentage of lot; and in 1929 the Multiple Dwelling law was passed superseding the act of 1901.

Manufacturing.—New York city is the leading manufacturing city in the U.S., a position it has held since 1824. In the second half of the 20th century the metropolitan area accounted for more than a fourth of the industrial production of the country's dozen largest industrial areas. At that time there were more than 35,000 manufacturing establishments in the city which employed nearly 1,000,000 persons. The ten leading manufacturing industries in terms of the number of workers employed were appar-

and other finished products; printing, publishing and allied industries; food and kindred products; electrical machinery; chemicals and allied products; fabricated metal products; textile products; machinery, excluding electrical; leather and leather products; and paper and allied products. Nearly 80% of the total manufacturing employment was in these industries.

TRANSPORTATION AND COMMUNICATION

Rapid Transit.—The problem of transportation and communication in New York city is unique not only because of the extraordinary concentration of people in certain areas at a given moment but also because of the narrow and elongated shape of Manhattan, and of the rapid growth and shifting areas of population that must be served.

The vast 237 route-mile city-owned rapid-transit system had its beginnings with the primitive steam locomotives that pulled cars along the Ninth avenue elevated railway, which opened in 1871 and extended slightly more than 3 mi. from Battery place near the southerly end of Manhattan to 30th street. The next decade witnessed its growth to 32.5 route-miles of track, forming four separate transit lines extending north and south on Manhattan. These lines were entirely private enterprises operated under perpetual franchises granted by the state legislature. For the next 20 years there were no extensions to the rapid transit lines on Manhattan, but some progress was made in other boroughs—the Third avenue "L" in Manhattan was extended into the Bronx across the Harlem river as far as 169th street in 1888, to 177th street by 1891, to Fordham road by 1901 and to its terminus at Bronx park by 1902. In Brooklyn the first elevated, the Lexington avenue line, was opened in 1885. This line was extended and other lines built until by 1900 the Brooklyn system had a route length of 62 mi. In 1902 the motive power of these elevated lines was changed from steam to electricity. In 1900 the first subway was planned and finally extended from the Bronx through Manhattan and under the East river to Brooklyn. This rapid transit system was a municipal undertaking. Between 1908–10 two tubes under the Hudson river connecting Manhattan with Hoboken and Jersey City and a connecting tube which extends up Sixth avenue from Cortlandt street to 33rd street were completed. In 1913 a new Lexington avenue line and the extension of the west side subway down Seventh avenue to lower Manhattan and then under the East river to Brooklyn were begun. A four-track subway on Broadway and Seventh avenue, Manhattan, extending through tunnels to Brooklyn and Queens was authorized at about the same time. In 1925 the city began building an independent subway system, the main unit of which, the Eighth avenue line, commenced operation in 1932. During the La-Guardia administration, many more miles of track were opened on the Independent subway and the new Sixth avenue line was completed. The Sixth avenue "L" was razed and buses rapidly replaced surface cars. Unification of the transit system of the city was accomplished in June 1940; through condemnation proceedings the city acquired title to "L" lines in Brooklyn and Manhattan which, with the exception of a part of the Third avenue line in the Bronx, were abandoned.

The New York City Transit authority administers the largest municipally owned transit system in the U.S., comprising a total mileage of nearly 800 mi. The subway division is divided into three systems; the Interborough Rapid Transit, the Brooklyn-Manhattan Transit and the Independent system.

Railroads.—The New York Central and the New York, New Haven and Hartford railroads have a common terminal in Manhattan (Grand Central terminal), at 42nd street and Park avenue; and the Pennsylvania has its terminal at 32nd street and Seventh avenue, with tunnels to Long Island and New Jersey. The Pennsylvania terminal is used also by the Long Island railroad, which has its own terminal at Atlantic and Flatbush avenues in the borough of Brooklyn. The other railroad terminals are on the New Jersey bank of the Hudson and are reached either by tunnel, ferry or subway.

Streets.—The first comprehensive street plan was the Randel plan, drawn up by John Randel, Jr., in 1807. By 1811 the plan was in effect, and with a few changes, notably the laying out of Madison avenue, midway between Fourth and Fifth avenues, north of 23rd street, and Lexington avenue between Third and Fourth avenues, north from 21st street, this is now the street plan of Manhattan as far north as 155th street. The 120,000 population at that time was concentrated south of Houston street. The plan provided straight line "avenues," with a uniform width of 100 ft. extending longitudinally along the island and separating block lengths ranging from 610 to 920 ft. At right angles thereto, "streets," usually 60 ft. wide, were laid out separated by a block depth of 200 ft. The plan included the extension of Broadway, which has a general direction diagonally across Manhattan to 79th street, whence it parallels the other avenues. The rapid growth of the city and the ever-increasing use of motor vehicles produced serious traffic congestion in many sections of the city and this necessitated extensive street widening and the development of new thoroughfares.

The Port authority operates the bus terminal, plus two motor truck terminals, one in New York and the other in Newark, and the Union Inland terminal in Manhattan.

Notable accomplishments in the city's highway system have been the West Side highway, a 13-mi. nonstop drive from one end of Manhattan to the other that connects directly onto the Henry Hudson parkway in the Bronx and finally with the Westchester county parkway system in Yonkers; the Franklin D. Roosevelt (East river) drive, a nonstop drive from the Battery to 125th street and then into the Harlem river drive; and the Major Deegan expressway that runs the length of the Bronx and connects the Triborough bridge with the New York State thruway. Other improvements have been the 3-mi. viaduct on the Jersey side of the river, leading from the Holland tunnel to the main highway to Trenton; the extension of the Hutchinson river parkway, the Henry Hudson parkway and the Bronx river parkway, extending for 15 mi. through Westchester county; the bridges and highways in the Triborough bridge project, opened in 1936; and the Belt parkway, primarily a three-lane superhighway, which from the Brooklyn-Manhattan tunnel rims the boroughs of Brooklyn and Queens for a distance of more than 40 mi.

The more notable streets include Wall street, on lower Manhattan, the centre of the financial district; Fifth avenue, with its fine shops, clubs, library and museum; Riverside drive, overlooking the Hudson; Park avenue, which continues as Fourth avenue above 32nd street to the Grand Central terminal and then from 45th street to the Harlem river, and is lined with fine apartment houses and office buildings in the middle section up to 96th street; the Bowery, which runs diagonally through the east side of lower Manhattan from the Brooklyn bridge to meet Fourth avenue at Eighth street; and Broadway, which extends more than 18 mi. from the southern tip of Manhattan to the northern limits of the city. In its middle part, from 10th to 79th streets, Broadway cuts through the heart of the business and amusement district. From 34th street to Columbus circle at 59th street it forms the centre of the automobile, theatre, moving picture, restaurant and nightlife sector.

Bridges and Tunnels.—There are eight bridges spanning the East river. One, completed in 1951, links the east Harlem area with a large playground and park on Ward's Island. The Brooklyn, Manhattan and Williamsburg bridges are suspension bridges and connect Manhattan with Brooklyn. The Brooklyn bridge, the first to span the East river, was opened in 1883. The Williamsburg bridge was opened in 1903, the Queensboro bridge in 1909 and the Manhattan bridge the same year. The Hell Gate bridge over the East river is exclusively for railroad traffic. The Triborough bridge over the East river, opened in 1936, actually consists of three bridges connected by several long viaducts over land, its arms extending into Manhattan, the Bronx and Queens. The vertical lift bridge between Randall's Island and Manhattan is one of the largest of that type in the country. The Bronx-Whitestone bridge, opened in 1939, connects the Bronx with Queens, as does the Throgs Neck bridge, opened in 1961.

The George Washington bridge, crossing the Hudson river, extending from a point near 178th street, Manhattan, to Fort Lee,

N.J., was opened in 1931 and is one of the longest suspension bridges in the world. A second deck below the original deck was opened to traffic in 1962.

The two-deck Verrazano-Narrows bridge between Brooklyn and Staten Island was opened in 1964.

The Harlem river is traversed by 13 bridges of various types and designs. The most notable is the famous High bridge (1848), which carries an aqueduct of the city's Croton water supply, and which was rebuilt in 1928 to remove impediments to navigation.

Transportation of passengers by rail between the boroughs of Manhattan, Brooklyn, the Bronx and Queens and New Jersey is provided by means of tunnels constructed below the beds of the East, Hudson and Harlem rivers. Vehicular transportation between Manhattan and Jersey City was made possible by the opening of the Holland vehicular tunnel in Nov. 1927. In Dec. 1937 the Lincoln tunnel, connecting 39th street in Manhattan with Weehawken in New Jersey, was opened. A third tube was added to this tunnel in 1957 making it the only triple underwater tunnel in the world. The Queens Midtown tunnel, finished in 1940, connects Manhattan on the east side at 36th and 37th streets with Long Island city. The Brooklyn-Battery tunnel was opened in 1950. This twin-tube 11,000-ft. structure was the longest underriver ventilated vehicular tunnel in the country at the time of its completion. It connects the southern tip of Manhattan with Gowanus parkway, which branches into the Belt system or into downtown Brooklyn. The Pennsylvania railroad has four tubes across the East river and two across the Hudson, and the Hudson and Manhattan railroad has two systems, each comprising two single-track tubes from Jersey City. The Brooklyn-Manhattan Transit system has six rapid-transit tubes under the East river, laid in pairs, and the Interborough Rapid Transit system also has three pairs of transit tubes leaving Manhattan.

Practically all of the railroad and rapid-transit tunnels were completed between 1900 and 1920. In connection with the Independent subway system, the board of transportation designed five new tunnels, four of which were opened for service in 1933 and one in 1936.

Ferries.—There were 11 ferries operating from New York city in the early 1960s. Four operated from City Island, the Bronx, to Hart Island; from the Battery, Manhattan, to St. George, Staten Island; from East 134th street, the Bronx, to North Brothers and Rikers islands; from 69th street, Brooklyn, to St. George. Others were operated by railroads, private companies and the federal government. The Staten Island ferry ride is one of the city's recreational features, offering a ten-mile, one-hour round trip through the New York harbour, and affording a view of the city's sky line, the Statue of Liberty and Governors Island.

Airports.—In 1947 four major airports in the metropolitan area were combined into a single integrated air-terminal system under the control of the Port of New York authority. These were the LaGuardia airport in Queens; the New York International airport at Idlewild in Queens, renamed the John F. Kennedy International airport in 1963; Newark airport in Newark, N.J.; and Teterboro airport in Teterboro, N.J. In addition, the authority operates the West 30th street heliport which was opened in 1956.

Telephone and Telegraph.—Between 1950 and 1960, the number of telephones in the city increased by more than 1,000,000 to make a total of more than 4,000,000. The volume of telegraph traffic is so great that the company operating the system designated the New York city area as a separate division. There are approximately 115 mi. of cable under the streets of Manhattan, used to speed distribution of local telegraph traffic. These cables are all concentrated in a relatively small area of 3 sq.mi. and there are entrances to approximately 1,000 buildings in the financial and midtown area.

International communications services are provided by coaxial and conventional underwater cables and landlines, radiotelegraph circuits, radiotelephone circuits and ship-to-shore radiotelegraph.

EDUCATION AND CULTURAL ACTIVITIES

Public-School System.—The public-school system is administered by a department of education of nine persons appointed by the mayor. The chief executive officer is the superintendent of schools, who is elected by the board for a term of six years.

The board of education has created the "600" schools for maladjusted students and those presenting disciplinary problems and has pioneered in the education of the gifted. Serious problems include the absorption of the numerous Puerto Rican children into the schools and the integration of Negro pupils into predominantly white schools.

Higher Educational Facilities.—The city provides higher educational facilities through the City University of New York (formerly College of the City of New York), which comprises City college, Hunter college, Brooklyn college and Queens college. City college was established as the Free academy in 1847. A modern structure in lower Manhattan houses its business school. Hunter college was founded in 1870 as the "normal and high school." In addition, New York is the seat of Columbia university (*q.v.*) and New York university, which was founded in 1831. In 1835 it moved to Washington square and in 1891 added a site of about 48 ac. on University heights in the Bronx. Fordham university was founded in 1841 as St. John's college. In 1846 it was turned over to the Jesuits and incorporated. The name was changed to Fordham in 1907. It is situated in the Bronx. Long Island university is in Brooklyn. In 1928 Yeshiva university (Jewish) was opened and it occupies buildings of ancient Semitic architecture in upper Manhattan. Among the professional schools are: the General Theological seminary (Protestant Episcopal); Union Theological seminary (Presbyterian); Jewish Theological Seminary of America; Cornell university medical college; Brooklyn law school; the Institute of Public Administration; the New School for Social Research; and the professional schools of the various universities. The chief technical institutions are the Mechanics institute, founded in 1820; Cooper Union (*q.v.*); and Pratt and Polytechnic institutes, both in Brooklyn. The State University of New York Maritime college is at Fort Schuyler in the Bronx.

In 1956 New York city and New York state combined to establish the Staten Island Community college offering either a two-year course in the liberal arts or a two-year program in varied categories of technical training. The Bronx Community college was founded in 1957 and the Queensborough Community college opened its doors in 1960. These three colleges are sponsored by the New York city board of higher education under the program of the State University of New York. Under the related city-state community college plan are two two-year colleges, the Fashion Institute of Technology and the New York City Community College of Applied Arts and Sciences.

Libraries.—The first public library in New York was the New York Society library, founded in 1754 in the city hall. It remained at the city hall until 1795 and was the library of congress when New York was the nation's capital. Other libraries are the Columbia university library (1754), that of the New York Historical society (1804) and the Mercantile library, founded in 1820 by merchants' clerks. The municipal library system consists of the New York Public library, serving Manhattan, the Bronx and Richmond; the Brooklyn Public library and the Queens Public library. There are also numerous college, university and important special libraries in the city.

Art and Architecture.—Augustus Saint-Gaudens is represented by his "Peter Cooper," the equestrian statue of Sherman, the Admiral Farragut statue, the bronze relief of the Rev. Henry W. Bellows and other works; John Quincy Adams Ward, by the "Pilgrim," "Shakespeare," "Indian Hunter" and a monumental bronze "Washington"; Frederick W. MacMonnies, by his "Nathan Hale," "Civic Virtue," "Horse Trainers and a Quadriga"; Daniel Chester French, by the "Alma Mater"; George Grey Barnard, by a fountain at Columbia; Karl Bitter, by "Abundance" and an equestrian statue of Franz Sigel; Anne Hyatt, by "Jeanne D'Arc"; Bartholdi, Kirke Brown, by an equestrian Washington; F. Auguste Bartholdi, the French artist, by "Lafayette"; H. P. Proctor, by a bronze group of panthers; and Edward Kemeys, by "Still Hunt." On the front of the Public library is a statue by Paul Bartlett. A group by Albert Weinter depicting the purchase of Manhattan Island is in the city hall of records. On Liberty Island the Statue of Liberty

by Bartholdi, a gift of France on the 100th anniversary of American independence, rises 305 ft. above the harbour. (*See* LIBERTY, STATUE OF.) Modern U.S. sculpture is well represented by the works of such men as William Zorach, Jo Davidson and Isamu Noguchi.

The largest collection of art objects in America is in the Metropolitan Museum of Art. Other museums of importance are the Whitney Museum of American Art, which exhibits works of U.S. artists, the Museum of Modern Art, and the Solomon R. Guggenheim museum, housed in a building designed by Frank Lloyd Wright.

Aside from the public museums, among the important art galleries is that of the Associated American Artists. The Cloisters in Fort Tryon park, a branch of the Metropolitan Museum of Art, was a gift of John D. Rockefeller, Jr. It contains an outstanding set of Gothic tapestries, "The Hunt of the Unicorn."

A few striking examples of 18th and early 19th-century architecture remained in the 1960s, notably St. Paul's chapel, designed by MacBean and built in 1764; the old church of St. Mark's-in-The-Bouwerie, completed in 1799; and city hall, the work of Joseph F. Mangin and John McComb, Jr., completed in 1812. James Renwick designed the Gothic Grace church, completed in 1845, and St. Patrick's cathedral, which was built between 1858 and 1879. After the Civil War Richard M. Hunt, a graduate and teacher in the Paris School of Fine Arts, began his American career. Among his first works were the Astor and Gerry houses and the old *Tribune* building. Charles F. McKim, William R. Mead and Stanford White were designers of the old Madison Square Garden, the Washington arch and the Metropolitan club. R. H. Robertson is known for his work on the American Tract Society and United Charities buildings. John Carrère and Thomas Hastings planned the National Academy of Design and the New York Public library; H. I. Hardenburg, the Waldorf, Savoy and Manhattan hotels and the American Fine Arts building; and Ernest Flagg, the Singer building, St. Luke's hospital and the Scribner building.

Since 1945 there has been an office building boom. Several of these structures and skyscrapers have been innovational from an architectural point of view. Conspicuous among these have been the United Nations group, the Seagram, 260 Madison Avenue and Manufacturers Trust Company (with its unbroken glass façade) buildings, Lever and Canada houses and the New York coliseum.

Music.—In the first quarter of the 19th century, the Park theatre became a famous stage for dramatic and musical art. In the 1840s and 1850s the musical centre was Tripler hall on lower Broadway, which became Metropolitan hall in 1854 and then, following its destruction by fire shortly afterward, was rebuilt and rechristened the New York theatre and Metropolitan Opera house. Later its name was changed to the Winter Garden. The present Metropolitan Opera house was built in 1883. In the latter half of the 19th century several other large halls for musical recitals were opened, notably, Steinway, Chickering, Hardman and Carnegie halls.

In the 20th century there has been a growth of interest in all forms of musical activity. Typical of this were the Lewisohn Stadium concerts, performed by the New York Philharmonic-Symphony orchestra and distinguished soloists before large audiences in the City college stadium. Besides the Metropolitan Opera company, opera was represented in New York city by the New York City Opera company at the City centre. Ground was broken in 1959 for the Lincoln Centre for the Performing Arts, part of the Lincoln Square development, and its Philharmonic hall was dedicated in 1962.

Literature.—Cadwallader Colden, author of the *History of the Five Nations* (1730), was perhaps the first New York author of general reputation. The first authors' club, the Ancient Club of New York, was founded in the latter part of the 18th century and later included among its members Washington Irving, Fitz-Greene Halleck, James Kirke Paulding and Joseph Rodman Drake. A little later John James Audubon, Richard Henry Dana, James Fenimore Cooper, Edgar Allan Poe, William Cullen Bryant, Herman Melville, John Bigelow, Julia Ward Howe and Robert Bonner were members of New York's literary life. In the 19th century the Bread and Cheese club brought together a most creditable group of writers. In the early 1920s Greenwich Village (*see* below) became the centre of American letters. During this period Edna St. Vincent Millay, Eugene O'Neill and Theodore Dreiser, among many, made this part of New York their headquarters.

The chief society of authors having headquarters in New York is the American Academy of Arts and Letters. Other notable literary organizations are the Authors' guild, Grolier club and Century association.

Theatres.—The first dramatic performances in New York were probably those given in a building on Pearl street by a company of actors from London in 1732. Another company from London came to New York in 1749. The real beginning of the permanent theatre in New York was, however, in 1750, when a company under the management of Thomas Kean and Walter Murray came from Philadelphia and established themselves in a house on Kip street (now Nassau), between John street and Maiden lane. Lewis Hallam arrived in 1753 from Virginia and erected a theatre in Nassau street, the first building constructed for theatre purposes, and opened it in 1753 with *The Conscious Lovers* and *Damon and Phelleda*. The first performance of *Romeo and Juliet* in New York was given at this theatre in 1754 with Mrs. Hallam as Juliet. This theatre was abandoned the same year and was converted into a church by a society of Calvinists. The next theatre was at Crugers wharf on the East river and was opened by David Douglass in 1758 with *Jane Shore*. Douglass also opened another theatre at the corner of Nassau and what is now Beekman street in 1761 with *The Fair Penitent* and later gave the first performance of *Hamlet* in New York; he also established the John Street theatre in 1767. In 1789, the first professional play by an American playwright, *The Contrast*, by Royall Tyler, was produced there.

In 1798 a three-story stone theatre, the Park, was built between Ann and Beekman streets on Park row, for Hallam and John Hodgkinson. This building was magnificent for its time, costing about $180,000. In 1837 New York had five theatres: the Park, Bowery, Olympic, Chatham and Richmond Hill. Palmer's Opera house was built in the 1840s as was the Astor Place Opera house, where the Astor Place riot occurred as the result of a dispute between friends of the U.S. actor Edwin Forrest and his English rival William Macready. Twenty-two persons were killed and 36 were wounded by the militia called to quell the disturbance. In 1850, P. T. Barnum brought Jenny Lind to the U.S. for a series of concerts which began at Castle Garden at the Battery. Similar "pleasure gardens" as Niblo's, the New York, Cold Springs, East River, Vauxhall and Ranleagh were utilized for concerts and other performances for which the capacity of theatres was inadequate. The Crystal palace at Sixth avenue and 42nd street was also a great amusement centre in the early 1850s.

By the middle of the 19th century the theatrical district was well established in the neighbourhood of Union square. The Academy of Music, the Union Square, Irving Place and Wallack's were the chief theatres in this area. By 1870, 23rd street had become the upper limit of the theatrical centre, with the Fifth Avenue theatre and Booth's. Ten years later the theatres had invaded the lower 30s with Daly's, the Standard, Wallack's and the Casino. In 1883 the erection of the Metropolitan Opera house at 39th street started an invasion of the 40s and by the end of the century, 42nd street had become the real centre of the theatrical district.

The modern theatre district comprises roughly a strip of Manhattan extending from 41st to 53rd streets, and from Fifth to Eighth avenues.

Scientific Collections and Learned Societies.—Chief of the scientific collections is that of the American Museum of Natural History. The Hayden planetarium is a part of this museum. The zoological park in Bronx park is under the control of the New York Zoological society. The botanical garden in Bronx park occupies about 400 ac. The museum contains a library, collections with about 1,800,000 specimens and research laboratories. The Brooklyn Institute of Arts and Science maintains another large botanical garden.

The Hispanic Society of America, founded by Archer M. Hunt-

ington, maintains an excellent museum of Spanish and Portuguese paintings, manuscripts, maps, coins and antiquities. Other interesting collections are in the museum of the American Numismatic society and the American Museum of Safety (industrial safety appliances).

The New York Historical society, the Long Island Historical Society of Brooklyn, the New York Genealogical and Biographical association, the Museum of the City of New York, the New York Academy of Medicine and the Academy of Political Science also deserve mention.

(For New York city press data *see* NEWSPAPER. For foundations *see* FOUNDATIONS, PHILANTHROPIC, etc. For museums *see* MUSEUMS AND GALLERIES.)

Clubs.—Club life in New York is less significant in the second half of the 20th century than in the earlier part of the century. The first social organizations of importance were the authors' Bread and Cheese club (1824) and the artists' Sketch club (1829). It was not until 1836, however, that club life in New York really began with the founding of the aristocratic Union and Hone clubs. The Knickerbocker (1871) was popular among the descendants of original New York settlers. The St. Nicholas was formed a little later for those whose ancestors were early residents of the colonies.

The Metropolitan (1891), with its costly house, was in fact a protest against the exclusiveness of many of the older clubs. The Union League (1863) was established for the purpose of aiding the Union, and its first work was the organization of regiments of Negro troops. To offset this Republican influence, the Manhattan was organized in 1864 to advance Democratic ideals.

The chief sport and athletic clubs are the New York Yacht (1844), the New York Athletic (1868) and the Racquet and Tennis. Other important clubs with more or less specialized interests are the Camera, Century, City, Colony, Engineers, Explorers, Harvard, Lambs, Yale, Lawyers, Lotos, Players and Salmagundi clubs.

Churches.—The Dutch Reformed church (1628), the first church in the city, is known as the Collegiate Church of New York city. The Presbyterians organized there as early as 1638 and were tolerated by the Reformed Church, but it was not until the English occupancy that they made their influence felt. In 1719 the first Presbyterian church was built in Wall street. It was not until 1847 that a Congregational church attained prominence in New York, when the Plymouth church of Brooklyn was founded with Henry Ward Beecher as pastor. In 1664 the Lutherans obtained permission from the English governor Richard Nicolls to establish a church. The first Lutheran church, at Broadway and Rector street, was destroyed in the fire of 1776. The Protestant Episcopal Trinity church was built in 1697 at Broadway and Wall street where Trinity church (1846) now stands. St. Paul's chapel (1766) at Broadway and Vesey street is the oldest church edifice in the city; Grace, St. Thomas', the Church of the Transfiguration, familiarly known as "The Little Church Around the Corner," and the Cathedral of St. John the Divine, at 110th street and Morningside avenue, are other notable Episcopal churches. The first Methodist church (1768) was erected in John street. The Baptists had built their first church on "Golden Hill," on John street between William and Nassau streets by 1728. St. Peter's (1785) was the first Roman Catholic church and in 1808 New York was made the seat of an Episcopal see. In 1858 the present St. Patrick's cathedral at Fifth avenue and 51st street was begun, and in 1879 it was dedicated.

PARKS AND RECREATION

The department of parks has two long-range objectives: the construction and rehabilitation of recreation plants and facilities, and the expansion of park acreage through reclamation. A consolidated department was established in 1934 and is directed by a commissioner appointed by the mayor. In all, in the second half of the 20th century, the park system consisted of more than 34,000 ac. Also under the jurisdiction of the department are public beaches, swimming pools and other recreational facilities ranging from archery to football fields and yacht basins.

Central park extends from 59th to 110th streets, between Fifth and Eighth (Central Park West) avenues. It was purchased in 1856 for about $5,500,000, and laid out and developed by architects Frederick Law Olmsted and Calvert Vaux. Van Cortlandt, Pelham bay and Forest parks are the largest generally devoted to outdoor sports and recreation. In Van Cortlandt park is the Van Cortlandt mansion, built in 1748 and now maintained as a museum. The Bronx park is noted for its zoological and botanical exhibits, the African veldt, opened in 1941, being one of its major attractions. Riverside park, in Manhattan, extends along the east bank of the Hudson river from 72nd to 129th streets, a distance of about three miles. City Hall park constitutes a part of what was called the "fields," or "commons," in the middle of the 17th century. Roger Morris park is the site of the Jumel mansion, the home of Mme Jumel, wife of Aaron Burr, and there Gen. George Washington made his headquarters during the battle of Harlem heights. In Audubon park was the home of the naturalist John James Audubon. Poe park, in the Bronx, is the site of the Edgar Allan Poe cottage, moved from its nearby original location.

Indoor recreation centres have been constructed with indoor pools; "golden age" centres are especially designed for older people; and a dance and concert schedule in the city's parks has been instituted; the Shakespeare workshop functions in Central park and the Wollman memorial alternates between square dancing and ice skating.

GREENWICH VILLAGE

Bounded on the north by 14th street, on the south by Spring street, running west from Broadway, Greenwich Village is a roughly triangularly shaped segment of New York city perhaps most commonly thought of as a home of American arts and letters. It is often associated with Bohemianism, radicalism, struggling artists and exotic night clubs and restaurants maintained chiefly for visitors. This atmosphere was a carry-over from the period before and after World War I, when the "Village" was locally considered the centre of the American literary and artistic renaissance. The Village has never relinquished its important role in the development of the experimental theatre and the off-Broadway theatre. The sidewalk art shows still persisted into the second half of the 20th century, and many artists still lived and worked in the Village, but the area was losing its uniqueness and early character before the impact of modern urban transformation. Some parts, however, still retained their former quaintness and charm. Southwest of Sheridan square and in the area west of the Avenue of the Americas was a maze of winding streets where could be found the age-worn dwellings erected by the burghers in the late 18th and early 19th centuries.

Elsewhere in the Village, other buildings were giving way to huge modern apartments and developments typical of a hundred other neighbourhoods. Houses and mews—converted stables with their interior gardens—that gave the Village its old-world look were rapidly being torn down. Washington square, at the foot of Fifth avenue, dominated by Washington arch, erected in 1892, was the last vestige of the dignity and taste of the early wealthy settlers who built there when Washington square was the centre of high society. Even the square, however, was gradually succumbing to the advances of the skyscraper apartments and New York university. In 1950 and 1951 the Rhinelander mansion and other fine old buildings along the northern border of the park were torn down. On the southern side of the park, "genius row," including the homes of some of the country's best-known artists and writers, had also disappeared.

NEW YORK, STATE UNIVERSITY OF, was established in 1948 to provide an adequate program of higher education for qualified youth of the state. It comprises about 50 separate, locally administered colleges throughout the state, almost half of them locally sponsored community colleges. *See* New York: *Education.*

NEW YORK FERN (*Dryopteris noveboracensis*), a beautiful North American fern of the shield-fern group, useful in the shady wild garden. While named after New York, it is native to a much greater region, occurring in moist woods from Newfoundland to Minnesota and southward to Georgia and Arkansas. The delicate pale green fronds, one to two feet high, rise on slender stalks (stipes) from widely creeping rootstocks. For general features of these and other ferns, *see* Fern.

NEW ZEALAND, an independent monarchical state and a constituent member of the Commonwealth of Nations, consisting of a series of islands in the southwest Pacific. New Zealand proper consists of the North Island (44,281 sq.mi.), the South Island (58,093 sq.mi.), Stewart Island (670 sq.mi.) and the Chatham Islands (*q.v.*; 372 sq.mi.). Within the political boundaries designated in 1842 and reaffirmed in 1863—from 33° S. to 53° S. and from 162° E. to 173° W.—are also: Campbell Island (44 sq.mi.); the islets of Snares, Solander and Bounty; Antipodes Island (24 sq.mi.) and Auckland Islands (*q.v.*; 234 sq.mi.); sometimes referred to as the minor islands or Subantarctic Islands. Off the North cape of the North Island are the Three Kings (3 sq.mi.). The Kermadec Islands (*q.v.*), annexed in 1887, lie 600 mi. N.E. of New Zealand.

The island territories administered by New Zealand comprise: (1) the Cook Islands (*q.v.*), which lie 2,100–2,800 mi. N.E. of New Zealand and include Niue, which is separately administered; these came under New Zealand control in 1901; (2) the Tokelaus (4 sq.mi.), which lie about 300 mi. N. of Western Samoa and in 1948 were declared to form part of New Zealand; they had a population in 1964 of 1,835. In addition, the Ross dependency (160,000 sq.mi.), that segment of Antarctica south of latitude 60° S. and between 160° E. and 150° W. longitude, was in 1923 brought under New Zealand jurisdiction. Western Samoa (1,097 sq.mi.) was administered by New Zealand from 1914 until it became independent in 1962. Together with the United Kingdom and Australia, New Zealand shares the trusteeship of Nauru Island.

Excluding the island territories and the Ross dependency, New Zealand has an area of 103,736 sq.mi. Territorial and administrative responsibilities extend from the south pole almost to the equator. Penrhyn, the most distant atoll in the Cook Islands, lies almost half way from Wellington (the New Zealand capital) to the North American continent.

This article consists of the following sections and subsections:

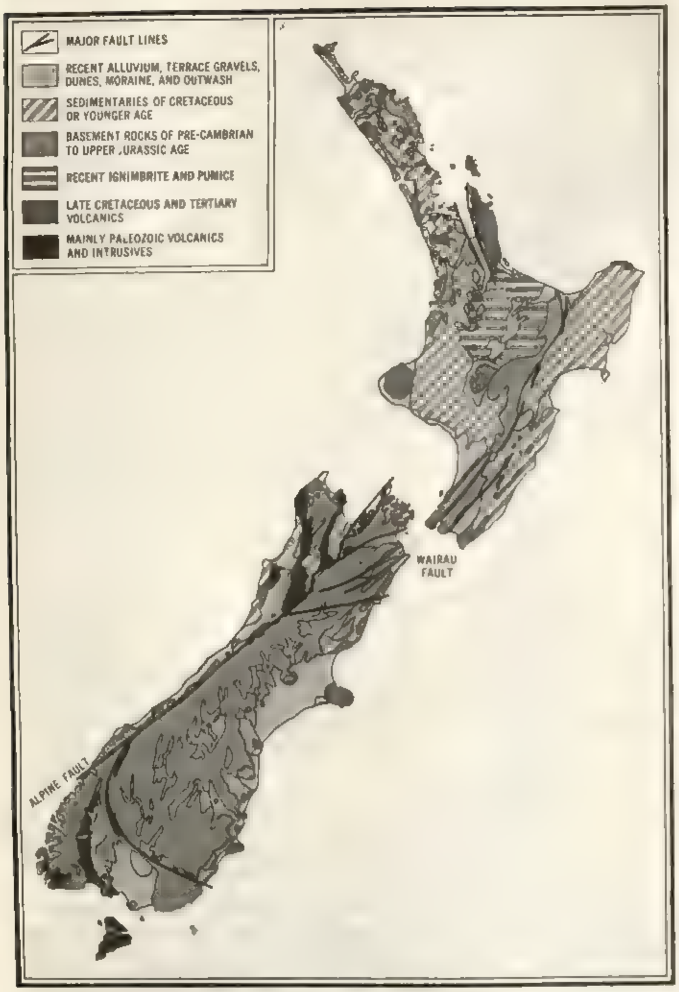
I. PHYSICAL GEOGRAPHY

1. Structure, Geology and Land Forms.—Structurally New Zealand is a section of the circum-Pacific mobile crustal belt, and forms the crest of a giant and unstable arcuate earth fold rising sharply from the ocean floor and paralleled closely eastward by a deep trough—the Hikurangi trench—which extends northeast into the Kermadec and Tongan deeps. The main islands are of youthful structure and recent origin. They assumed their present form and mountainous character as a result mainly of late Pliocene and Pleistocene diastrophism and mountain building. Contemporary earthquakes and active volcanism in New Zealand may represent the final stages in this relatively recent and catastrophic disruption of the Pacific's southwestern rim.

This period of mountain building followed prolonged, though interrupted, sedimentation dating from the late Cretaceous. The diastrophic disturbance began with gentle folding in the Oligocene, mounting gradually to a climax which, in some areas, was as early as the Miocene and elsewhere as late as mid-Pleistocene. The later phases of this "Kaikoura orogeny" were characterized by deformation and uplift through massive and widespread block faulting which, with the attendant volcanism, left a profound impression on the land forms and landscapes, creating what has been termed "a concourse of earth blocks." Active subsequent denudation has not destroyed, nor effectively masked, the structural and tectonic land forms created in a period of late Cretaceous, Tertiary and Quaternary diastrophism.

Rocks of varied age and composition occur in remarkable range and variety. But while the North Island lacks metamorphic and plutonic rocks and sedimentaries older than Permian, the South Island has a remarkable variety of metamorphic and intrusive rocks and a suite of sedimentaries ranging from possible Pre-Cambrian to Quaternary, though it lacks the North Island's spread and variety of younger volcanic rocks, ash and pumice.

The "undermass" consists of the stratified rocks of Jurassic or greater age, generally strongly folded and widely metamorphosed; the more altered rocks being unfossiliferous and their age uncertain. All were strongly folded between the Jurassic (a period of widespread deposition) and the upper Cretaceous, and were deeply eroded. The covering strata were deposited on the



K. B. CUMBERLAND

GENERALIZED GEOLOGY AND STRUCTURE OF NEW ZEALAND

eroded surface of the undermass and consist of weak sedimentaries of from upper Cretaceous to upper Tertiary and Quaternary age. Crustal deformation accompanied the deposition of the cover, intensifying until the Plio-Pleistocene peak of the Kaikoura orogeny. Both younger rocks and the undermass beneath them were first folded, later violently faulted and subsequently eroded. Much of the surface is now occupied by later accumulations—unconsolidated post-Tertiary gravels, sands and clays, volcanic ash and pumice sands. Taken as a whole, New Zealand derives its distinctive and varied scenery largely from the youthfulness of the structure, geology and land forms.

There are sharp contrasts between the two main islands. In the North Island, where hill country is much more characteristic than mountain landscapes, the surface most commonly consists of deep sandstones, siltstones and mudstones of late Cretaceous and Tertiary origin, much of it blanketed with late Quaternary volcanic debris. In the South Island, with its rugged and dominantly mountain terrain, the undermass is widely exposed.

The North Island.—Most of the North Island is hilly, its surface consisting of weak sedimentaries of the cover and later marine, alluvial and volcanic accumulations. Mountain landscapes and exposure of the island's old and hard skeleton are largely confined to the narrow, much fault-margined axial ranges extending northeastward from Cook strait in the Rimutaka, Tararua, Ruahine, Kaimanawa, Kaweka, Huiarau and Ikawhenua ranges toward the Bay of Plenty. Of Lower Mesozoic greywackes, these form a sharp divide between east and west. To the east, extending from Cape Palliser to East cape and including the structurally complex Raukumara peninsula, is the largest remaining accumulation of Upper Jurassic, Cretaceous, Tertiary and Quaternary sediments, consisting of greywackes, sandstones, siltstones, massive mudstones, bentonitic clays, thin limestones and conglomerates. In the late Tertiary the region was strongly folded on a northeast-southwest axis and the folds cut across by transcurrent (strike-slip, or lateral) faults still active; earthquakes there are as frequent as anywhere in New Zealand. Except for the gravel-floored Wairarapa lowland trough, the small alluvial Ruataniwha and Heretaunga plains (Hawke's Bay) and the Waipaoa flats in Poverty bay, the region is hill country, most of it steep and broken, much of it unstable and often affected disastrously by soil erosion and man-induced mass movement.

The other mountains in the North Island are the isolated Quaternary andesite cone of Mt. Egmont (8,260 ft. and active only 250 years ago) and the clustered active cones of Tongariro National park (Ruapehu 9,175 ft.; Ngauruhoe 7,515 ft.; and Tongariro 6,548 ft.). Between them, and extending from northern Taranaki to the western foot of the Tararua-Ruahine ranges, is steep and broken hill country deeply dissected by a close net of dendritic streams fed by heavy and regular rainstorms and cut into a great depth of near-horizontal blue-gray mudstones ("papa") and yellow-brown sandstones.

In the centre of the North Island is the volcanic plateau, or thermal belt, with the greatest expanse of Recent and Pleistocene volcanic materials in New Zealand and, between Tongariro National park and White Island, a concentration of contemporary volcanic activity. The underlying greywackes and the faulted structure of the undermass are hidden beneath great ignimbrite sheets of 2,000 cu.mi. estimated volume. The ignimbrite, or welded tuff, was probably formed by the consolidation and welding of hot rhyolitic fragments suspended in gas clouds from catastrophic Pleistocene eruptions in the Lake Taupo area. The faulted and dissected mesa-like surface of the ignimbrite is buried under layers of pumice which blanket and soften the surface over wide areas now widely planted with introduced forest trees.

From the rim of the volcanic plateau, the North Island projects northwestward in the North Auckland and Coromandel peninsulas. There the rocks and land forms are diverse and varied. Deformation is mainly the result of faulting and block tilting but several broad folds with north-south axes are discernible. The Hauraki gulf and Thames-Piako lowland are part of a fault-defined trough. The northern peninsulas have exposures of the greywacke basement and pocketed patches of Jurassic, Cretaceous and Tertiary sediments and Tertiary and Quaternary volcanics. The latter are often basaltic, as in the lower Waikato valley, on the Auckland isthmus and at Kerikeri. The volcanic rocks constituting the Coromandel peninsula and Great Barrier Island are largely andesites, dacites and rhyolitic lavas and tuffs of Miocene and Pliocene age. Both peninsulas have an irregular drowned coastline (with wide shallow embayments like the Manukau, Kaipara and Hokianga harbours) although in the north at Ninety Mile beach the sweeping west coast is smoothed and straightened by vast recent accumulations of sand.

The South Island.—Mountain terrains occupy almost three-quarters of the South Island. The Southern Alps, deeply fretted and glacially eroded, occupy the waist of the island and reach 12,349 ft. in the ice-capped peak of Mt. Cook. Farther north mountain terrains occupy almost the whole width of the island. There the Kaikoura and Seaward Kaikoura ranges parallel the main Spenser mountains and St. Arnaud range, separated by deep valleys cut along the tectonic lines of transcurrent faults. All these lofty folded and faulted mountain masses consist of undifferentiated (lower Mesozoic) greywacke—indurated sandstones and argillites. The belt of block-mountain horst and interspersed grabens across Otago from the outskirts of Dunedin to Mt. Aspiring (9,957 ft.) near the west coast is built of a great thickness of chlorite schists of doubtful late Paleozoic–early Mesozoic Age. The third mountain landscape, the ancient dioritic igneous block of Fiordland, consists of highly metamorphosed gneiss formed early from lower Paleozoic and possibly Pre-Cambrian sedimentaries. Fiordland is thus structurally and lithologically one of the oldest parts of New Zealand. It is essentially an ancient plateau mass with summits of 5,000–7,000 ft., into which Pleistocene glaciers have cut nearly vertically walled, thousand-foot-deep valleys, those

on the west having been since invaded by spectacular deep fiord incursions of the sea (Milford, George, Doubtful, Dusky and other sounds) and those on the east by moraine-dammed finger lakes and their tributary arms (Lakes Te Anau, Manapouri, Monowai, Hauroko and Poteriteri).

To the east the mountains descend to the sea along the coast of Marlborough, at Shag point (east Otago) and again in Southland west of Te Waewae bay. Elsewhere they give place to plains, low hills and downs. The largest lowlands are the Canterbury and Southland plains, the former extending more than 100 mi. from northeast to southwest (except where interrupted by the deeply eroded and sea-invaded twin late-Tertiary basalt domes of Banks peninsula) and as much as 40 mi. inland. The Canterbury plain, the largest land form of sedimentary origin in New Zealand, is an enormous and deep lens of gravel and sand worn from the greywacke Alps and deposited by swollen rivers as a series of gently-inclined piedmont alluvial fans. Other smaller alluvial plains of recent deposition have been built by the Wairau and Awatere rivers in Marlborough, by the Waitaki, by the Clutha in Otago and by the Waiau in Southland. Elsewhere remnants of the covering strata intervene between the highland and the plains or between the mountains and the east coast. In Marlborough, north Canterbury and south Canterbury-east Otago these remnants are principally of upper and lower Tertiary sedimentaries, maturely eroded into undulating hills and smooth low downland, often plowable.

In Southland, the angle between the schist block mountains of Otago and the lake-defined eastern margin of the Fiordland gneiss plateau is occupied by a syncline. On its northern flank Carboniferous, Permian and undifferentiated Paleozoic rocks extend in parallel bands across the country. Triassic and Jurassic rocks also occur more extensively than elsewhere in New Zealand; in the Hokonui hills are 30,000 ft. of steeply dipping Triassic and Jurassic strata in 90 separate beds. Small patches of the cover remain and, although Cretaceous rocks are few and thin, they include the important coal measures at Kaitangata, Ohai and Nightcaps.

The diverse mountainlands are abruptly terminated westward by the Alpine fault, the most prominent structural feature in the South Island. It extends for 300 mi. straight and unbroken, along the western foot of the Southern Alps from the mouth of Milford sound to Lake Rotoroa in Nelson district, whence it continues northeastward for another 90 mi. in the Wairau fault to Cook strait near Blenheim. West of the fault lie the narrow Westland plain and the geologically complex and inaccessible mountain country of Nelson. The narrow coast strip of Westland, where the Fox and Franz Josef glaciers, though retreating, still extend in subtropical forest to within a few miles of the coast, is an irregular dump of glacial and alluvial materials, which almost hides the oldest rocks in New Zealand. These, unfossiliferous and possibly Pre-Cambrian greywackes and argillites, granitic batholiths and gneiss, occur as broken hill country in south Westland and as foothill spurs of the Alps. In north Westland, Cretaceous and Tertiary sediments, including Coal Measures, form part of the cover. There, too, is the distinctive red-coloured, uranium-bearing Hawk crag breccia. In Nelson, geologically the most interesting part of New Zealand, occurs a great syncline with rocks closely matching those of Southland. In the Marlborough sounds block west of the Wairau fault, a sequence of Paleozoic schists, Trias-Jura greywacke, Carboniferous and Permian sediments, deeply dissected, plunges northward into Cook strait to produce an intricate ria coastline.

2. Rivers, Lakes and Hydrology.—New Zealand is rainy and well-watered; it is also mountainous, hilly and corrugated. Half the surface has mountain land forms and another quarter consists of steep and broken hill country. Average elevation is high; slopes are generally steep and broken; thus runoff moves swiftly seaward. The country is effectively drained by numerous rivers and streams, but none is remarkable in length or volume and few are of value for navigation. All flow swiftly and many are obstructed by bars. The Waikato, draining much of the Tongariro National park area into Lake Taupo and much of the North Island to the Tasman sea, is the longest river (270 mi.). Other North Island rivers are the Wanganui (180 mi.), Rangitikei (130 mi.)

PHYSICAL FEATURES OF NEW ZEALAND

and Manawatu (120 mi.), all draining to Cook strait. In the South Island the longer rivers, reaching back to the alpine highland, are fed also by ice and snowmelt and have a more marked and regular seasonal regime. Such snowmelt rivers as the Waimakariri, Rakaia and Rangitata formed the piedmont plains of Canterbury. The Clutha (210 mi.), Taieri (175 mi.), Mataura (140 mi.), Waiau (Southland, 135 mi.), Waitaki (135 mi.), Clarence (130 mi.) and Buller (110 mi.) are the most important in the South Island.

Although of little value for transport, many New Zealand rivers are important sources of hydroelectric power, such as the Waikato, Rangitaiki and Mangahao in the North Island, and the Waitaki, Cobb, Clutha and Waipori in the South Island. The Rangitikei, Motu, Mohaka and Kaituna rivers in the North Island and the lake-fed rivers of Otago and Southland are all potential hydroelectric sources.

New Zealand's wealth and variety of lakes derive from the youth of the structure and land forms, from Pleistocene glaciation, from relatively recent tectonic disturbance and from denudational processes. Lake Taupo (238 sq.mi.) occupies a fault depression; Lake Waikaremoana (21 sq.mi. and 840 ft. deep) was created when a landslide blocked a deep V-shaped valley. The "cold lakes" of Otago and Southland occupy overdeepened glacial trenches, mostly with floors below sea level. Lake Wakatipu, 48 mi. long and averaging less than 2 mi. in width, has its surface at an altitude of 1,017 ft. but its depth reaches 1,239 ft. The largest South Island lakes are Te Anau (136 sq.mi.), Wakatipu (113 sq.mi.) and Manapouri (55 sq.mi.). All are in superb alpine settings.

Most lakes are valuable as regulators of stream and river flow and for their water storage capacity. This is important when they are drained by rivers used for hydroelectric power, as in the case of Lake Taupo feeding the Waikato river. Other lakes (Waikaremoana, Coleridge, Tekapo, Pukaki and Hawea) are tapped di-

rectly to drive turbines. A series of narrow finger lakes has been created by damming rivers, notably the Waikato, Waitaki and Clutha.

3. Climate.—New Zealand has a temperate, mild and equable climate, with abundant precipitation and (paradoxically) a large proportion of sunshine. New Zealand extends through 13° of latitude, but this contributes far less to the strong regional climatic contrasts than do the elevation and mountainous character of the two main islands. Although parts of the northern peninsula and the Auckland isthmus are almost free of frost, and frosts at sea level are commoner with increasing latitude, there are much sharper temperature contrasts between coastal areas and adjacent interior basins, ranges, valleys and plateaus, while extraordinary contrasts in volume, seasonality and character of precipitation occur to windward and seaward of mountain barriers. Thus interior and easterly situations in the South Island experience considerably higher midsummer daily maximum shade temperatures than Auckland or places north of it; and while Milford sound has an average annual precipitation of 253.3 in. on 193 raindays, Alexandra (about 80 mi. E.) has 13.2 in. on 100 raindays and Invercargill 42.8 in. on 199 raindays. Invercargill enjoys 1,670 hr. of bright sunshine annually; but Tauranga with 53 in. of rain enjoys nearly 700 hr. of sunshine more each year than Invercargill.

New Zealand's daily weather is produced by the regular migration eastward of anticyclonic systems with centres usually northward of the country, and of the active meridional frontal zones and enclosed depressions between the anticyclonic systems. Prevailing winds are westerly, with considerable daily variation in speed, direction of movement and origins of the air masses affecting the country. (K. B. C.)

4. Vegetation.—The most characteristic feature of New Zealand vegetation, but one it shares in some degree with other "oceanic" islands, is the very large proportion of endemic species (species peculiar to it). In this it affords a striking contrast to the flora of the "continental" British Isles, with almost no endemics, although the total of wild species is similar in both areas. Of the different kinds of flowering plants and ferns in New Zealand that appear to belong to the primitive vegetation, probably three-quarters at least are endemic. These include many that are prized as garden shrubs, for instance, the evergreen veronicas (*Hebe*), the daisy bushes (*Olearia*), the South Sea myrtle (*Leptospermum*) or, for the alpine and herbaceous gardens, *Celmisias*, the giant forget-me-not (*Myosotidium nobile*) from Chatham Islands, and the white buttercup *Ranunculus lyallii*. But these latter exemplify a marked feature of many native New Zealand species, namely that they are often difficult to maintain in cultivation.

When the Europeans first came to New Zealand the natural plant communities clothed most of both islands and consisted mainly of evergreen forests and tussocky grasslands. The original vegetation still remains in some places. In the higher rainfall areas of the North Island, for example, occur the famous Kauri forests dominated by the giant conifers. Here too, especially in the gullies, are to be seen the magnificent groves of tree ferns sometimes attaining a height of 20 to 30 ft. In the areas of lower rainfall in the South Island evergreen forests are dominated by the southern beeches (*Nothofagus*).

Other characteristic forest trees are the rimu (*Dacrydium cupressoides*), the totara and kahikatea (*Podocarpus* species) and the tawa (*Beilschmiedia*).

In coastal regions notable features were the areas largely occupied by New Zealand flax or flax lily (*Phormium*, *q.v.*). In the South Island especially, vast areas were originally occupied by natural grasslands, the most conspicuous constituent species being the large tussock-forming grasses, the species of *Danthonia*, *Festuca novae-zealandiae* and *Poa caespitosa*.

With the advent of the Europeans and the subsequent extensive development of sheep farming, the areas occupied by the primitive vegetation have been very greatly diminished; moreover, excessive grazing has often led to serious erosion problems. This replacement of the continuous carpet of natural vegetation by increasingly open conditions, depending on the degree of exploitation, has provided habitats for colonization by species introduced through overseas trade. By 1940 about 500 such alien species appeared to have become established and of these nearly half are now either abundant or common.

The relationships of the flora of New Zealand are best indicated by the geographical distribution of the constituent genera, numbering about 390. Of these 10% are endemic, about one-quarter have Malayan affinities and 80% are confined to Australasia. A small number of species (about 4%) are found in the subantarctic area though not in other parts of Australasia. (E. J. S.)

5. Animal Life.—The terrestrial vertebrates of New Zealand are remarkable for their high degree of endemism and for the prevalence of primitive forms. The only indigenous mammals are several species of bats. Birds were originally abundant; there are 251 recent indigenous species, of which 161 breed in New Zealand. The forest-dwelling types include many of ancient Malayan origin while others have more recent Australian affinities. From long isolation many birds such as the kiwi (*q.v.*), huia, fern-bird, saddleback and kakapo now have no near relatives among overseas birds. Through advancing settlement and competition with introduced species, the huia and the native quail and thrush are extinct, while the stitchbird, kaka, kiwi and kokako (crow) are very rare. In 1948 colonies of the large flightless rail *Notornis* (takahe), formerly thought to be extinct, were discovered in Southland. Certain species adapt themselves to changing conditions; the tui, pukeko, morepork owl, pipit and grey warbler are becoming re-established and no doubt other species would rapidly increase if effectively protected. Among water birds the cormorants are especially characteristic, with 16 species and subspecies, mostly endemic. The New Zealand region seems to have been the centre of distribution of the penguins. All but one of the recent genera are represented while the fossilized remains are of the oldest and largest forms known.

Of the native reptiles the lizardlike tuatara (*q.v.*) is most remarkable in being the only survivor of an otherwise extinct order. No longer present on the mainland, it still flourishes on several outlying islands. Turtles and snakes are represented only by a few marine forms straying from tropical waters.

Geckos include about ten species, all endemic, and peculiar as the only known viviparous forms. Species of the widely distributed Pacific genera *Gehyra* and *Lepidodactylus* have been recorded. The remaining lizards are small skinks of two genera, *Leiolopisma* and *Sphenomorphus*. The only indigenous amphibian is a small primitive frog, *Leiopelma*, whose three species are rare and extremely local. The common frog is *Hyla aurea*, which, with the whistling frog (*Hyla ewingii*), was introduced from Australia. The fresh-water fishes are comparatively few. Notable genera are *Galaxias* (native trout), *Neochanna* (mudfish), *Gobiomorphus* (bully), *Prototroctes* (smelt) and *Retropinna*. *Galaxias attenuatus* breeds in tidal waters and is fished locally as white-bait. There are two species of eels and a lamprey (*Geotria australis*) which, like several of the fishes, has affinities with South American forms.

The terrestrial invertebrate fauna is markedly incomplete. The forest-dwelling *Peripatus* (Onychophora, *q.v.*) is widely distributed but distinctly local. The most abundant insects are the beetles, flies and lepidopterans. The moths lack most of the higher groups and have South American rather than Australian affinities. Butterflies are represented by the families Nymphalidae and Lycaenidae; but only four species are common. Anopheline mosquitoes do not occur. Among arachnids the katipo spider (*Latrodectus katipo*) is dangerously venomous, but scorpions are absent. There is a peculiar fresh-water crayfish, *Paranephrops* with several species.

Resolution, Kapiti and Little Barrier islets are sanctuaries for the native fauna. The law requires that, as far as possible, native flora and fauna shall be preserved and introduced flora and fauna exterminated in the national parks. These parks (Egmont, Tongariro and Urewera in the North Island, and Abel Tasman, Arthur's Pass, Fiordland, Westland, Mount Cook and Nelson Lakes in the South Island) have a total area of 7,153 sq.mi. of which Fiordland National park occupies 4,724 sq.mi. (W. R. McG.)

II. HISTORY

European settlement of New Zealand began in the late 18th century; its Polynesian history goes back to the early Christian centuries. In the 19th century the country became predominantly British in the face of determined resistance from the indigenous Maori tribes; subsequently the two races achieved considerable harmony. Upon land bought or wrested from the Maoris the settlers established a society dependent upon agrarian resources and overseas markets. In these circumstances a small population (less than 2,500,000 by the 1961 census) became prosperous and contented.

Discovery.—Little is known about the time or the manner of arrival of the first inhabitants, except that they came over the sea from the north. Chronologies based upon Maori oral traditions cannot be trusted. Recent archaeology indicates a much longer Polynesian occupancy than had earlier been supposed; other studies point to accidental drift voyages as the means of settlement. No more is certain than that the Maoris represent the southernmost point reached by Polynesian expansion in the Pacific. (*See* also OCEANIA.)

The Polynesian period has been divided into an early "Moa-hunter" and a later "Classic Maori" phase, but the transition from early to late is unexplored. In the South Island, if not elsewhere, the first Polynesians found moas (flightless birds) in immense numbers on tussock grasslands. Here was their major food supply. The "Classic Maori" found later by Europeans had only faint memories of the moa, and was an agriculturalist. The 18th-century Maori population was most dense in the warmer northern parts of the country, where the Maori (*q.v.*) variant of Polynesian culture had reached its high point, particularly in the arts of war, in canoe construction, in building, weaving and agriculture. Estimates of the extent of the Maori population vary widely; it was probably not more than a few hundred thousands. Numbers were to drop sharply in the first century of European influence, from the late 18th to the late 19th centuries.

The first European to discover New Zealand was a Dutch sailor, Abel Janszoon Tasman, who sighted the coast of Westland in Dec. 1642. His sole attempt to land brought only a clash with a South Island tribe in which several of his men were killed. After his voyage, the western coast of New Zealand became a line upon European charts and was thought of as the possible western edge of a great southern continent.

In 1769–70 James Cook (*q.v.*) completed Tasman's work by circumnavigating the two major islands and charting them with a remarkable degree of accuracy. His first contact with the Maoris was violent, but harmonious relations were later established. On this and on later voyages, Cook, with the explorer and naturalist Joseph Banks, made the first systematic observations of Maori life and culture. Cook's journal, published as *A Voyage Towards the South Pole and Round the World* (1777), brought the knowledge of a new land to Europeans. He stressed the intelligence of the natives and the suitability of the country for colonization, and soon colonists, as well as other discoverers, followed Cook to the country he had made known.

Early European Settlement.—Apart from convicts escaping from Australia and sailors seeking asylum with Maori tribes, the first European New Zealanders sought profits—from sealskins, timber New Zealand flax and whale oil. Early New Zealand was an offshoot of Australian enterprise in whaling and other activities; Sydney, New South Wales, founded as a convict settlement in 1788 became a base for South Pacific whaling, and Kororareka (now called Russell), in the far north of New Zealand, became a stopping place for American, British and French deep-sea whalers. Around both islands Australian firms set up tiny settlements of land-based bay whalers. Traders supplying whalers drew Maoris into their economic activity, buying provisions, supplying trade goods, implements, muskets and rum. Initially the Maoris welcomed the newcomers; while the tribes were secure, the European was a useful dependent.

Maoris went overseas, some as far as England. A northern chief, Hongi Hika, amassed presents in England, which he exchanged in Australia for muskets; back in New Zealand he waged devastating war on hereditary enemies. The musket traveled south; a series of tribal wars, spreading from north to south, displaced populations and disturbed landholdings, especially in the Waikato, Taranaki and Cook strait areas. Europeans were soon to found colonies in these unsettled regions. Missionaries quickly followed the traders. Between 1814 and 1838 Anglicans, Wesleyans and Catholics set up stations. Samuel Marsden, Henry Williams, Octavius Hadfield and a French Catholic bishop, Jean-Baptiste-François Pompallier, were important leaders. Success was initially slow, but by the mid-19th century most Maoris adhered, for varying reasons, to some form of Christianity.

All these newcomers had a profound effect upon Maori life. Warfare and disease reduced numbers; new values, pursuits and beliefs destroyed tribal structure. Christianity cut across the sanctions and prohibitions which had supplied social cohesion. A capitalist economy, to which Maoris were introduced both by traders offering new inducements (for instance the brief demand for flax) and missionaries bringing new agricultural techniques, altered the whole material basis of life. At first in the north, and later over the whole country, a process of adjustment began which has not yet been completed. By the late 1830s, chiefly through the Australian link, New Zealand had been joined to Europe. Settlers numbered at least some hundreds, and there were certain to be more. Colonization schemes were afoot in Great Britain, and Australian graziers were buying land from the Maoris. These circumstances determined British policy.

ANNEXATION AND FURTHER SETTLEMENT

In 1838 the British government decided upon at least partial annexation. It commissioned William Hobson, a naval officer, as lieutenant governor and consul to the Maori chiefs in July 1839; he became governor in 1841. Hobson, in the event, annexed the whole country, the North Island by the right of cession from the Maori chiefs and the South Island by the right of discovery. From June 1839 to May 1841 New Zealand was legally part of New South Wales. Before declaring the annexation of New Zealand, Hobson went through a process of discussion with the northern chiefs from which emerged the so-called treaty of Waitangi (Feb. 1840). Under this instrument, Maoris ceded sovereignty to the crown in return for protection and guaranteed possession of their lands; they also agreed to sell land only to the crown. Hobson promised an investigation into past "sales" of land to private individuals to ensure fair dealing. This treaty imposed a strong moral obligation upon the British government to act as guardian to the Maoris.

Even before annexation had been proclaimed, the first organized planting of an English colony was under way. The New Zealand Association, founded in 1837 to colonize on the principles laid down by Edward Gibbon Wakefield (*q.v.*), sent a survey ship, the "Tory," in 1839. The agents on board were to buy land in both islands around Cook strait. The company moved hastily because its founders were aware that British annexation was likely, and would entail a crown monopoly of land sales and a consequent increase in price. "Purchases" were effected in great haste before Hobson could bring to an end such private transactions. Little effort was made to seek out the true Maori owners; this would have been difficult as Maori ownership was communal and titles had been disturbed by the musket warfare of the early part of the century. The company, combining skilful propaganda with outright trickery and brutality, enforced its claim to the land upon which New Plymouth, Wanganui, and Wellington in the North Island and Nelson in the South Island were founded in the 1840s. Later, through the crown, it secured other areas in the South Island where Otago (1848) and Canterbury (1850) were planted by separate associations. Meanwhile, Hobson moved the seat of government south from the Bay of Islands, bringing Auckland into existence (1841).

In the early 1840s settlement and government began to alarm the Maoris. In the Cook strait area a formidable chief, Te Rauparaha, obstructed settlement. Near the Bay of Islands there was open warfare and Kororareka was repeatedly raided. Neither Hobson (d. 1842) nor his successor Robert FitzRoy (*q.v.*) pos-

sessed the means or the resolution demanded by the situation. George (afterward Sir George) Grey (*q.v.*), who became governor in 1845, had money and troops, and the will to use them. His victories brought a peace which lasted from 1847 until 1860. Hone Heke, the northern leader, was thoroughly defeated (1846), and in the south a likely uprising was prevented. Racial strife had been accompanied by economic distress. In the mid-1840s the nascent economy was depressed until the Australian gold rushes of the 1850s offered a market for foodstuffs to the New Zealand farmer, settler and Maori alike.

By the end of the 1840s racial and economic trouble gave way to political agitation. The leading settlements, apart from Auckland, began to campaign for representative government in place of Grey's personal rule. He, while refusing to give way, helped to draft the New Zealand Constitution act (1852) which was designed to meet all the settler demands. He sought not to prevent the introduction of self-government, but to delay it until he had determined both native and land policy. He wished to begin the rapid assimilation of the Maoris (with whom his relations were excellent) to the British pattern. He also wished to bring in a land policy which would safeguard the small farmer against the great owner. He believed he had secured these goals by the time of his departure at the end of 1853.

Responsible Government.—When the Constitution act came into operation New Zealand was divided into six provinces, Auckland, New Plymouth (Taranaki), Wellington, Nelson, Canterbury and Otago, each with a superintendent and a provincial council. The central government consisted of a governor, a legislative council nominated by the crown, and a lower house, elected upon a low property franchise for a five-year term. This general assembly did not meet until 1854; it then embarked upon a quarrel with the acting governor, Colonel Robert Henry Wynyard, which was not ended until the achievement of full responsible government, *i.e.*, a system under which the governor could act in domestic matters only upon the advice of ministers enjoying the confidence of the elected chamber. Henry Sewell and James FitzGerald, of Canterbury, led the representatives in this struggle, against the opposition of E. G. Wakefield, who, having first moved the resolution for responsible government, then secretly opposed it, while serving as extra-official adviser to the acting governor. The colonial office conceded responsible government in 1856. The next governor, Thomas Gore Browne, reserved Maori affairs to the competence of the governor alone.

For most purposes, during the 1850s, New Zealand was administered not by central but by provincial institutions. These authorities (nine in number by the time of their abolition in 1876) directly affected the settler through their administration of land and control of immigration and public works. The native department, directly under the governor, bought land from the Maoris; the provincial governments settled it, regulated immigration, built roads and bridges. Until the wars of the 1860s the central legislature was less important, though its ultimate authority remained.

Each province disposed of a revenue arising from land sales, and upon this revenue depended its strength. Canterbury and Otago, with hardly any Maoris, grew wealthy, spending their money upon communications, immigration and education. Other provinces were either less fortunate or less wise, and enjoyed smaller success. In the North Island numerous and anxious Maoris held on to desirable land. Here most land available for settlement had been taken up by the end of the 1850s, a good deal of it by speculators, and some of it given away to attract immigrants. The island remained largely without roads until the 1870s, so impecunious were its governments. But by that time the major obstacles to settlement had been removed—the continuing power of the tribes. This was the result of a decade of war.

Racial Conflict.—In the 1850s race relations deteriorated. The settler population and the demand for land, especially pastoral land, increased. Many Maoris, fearing for their future, became reluctant to sell more land. In the Taranaki province, where the land shortage was acute, both settlers and those Maoris willing to sell were opposed by Wiremu Kingi, chief of Te Atiawa. In the Waikato, where good land was coveted by settlers and speculators, an elderly chief, Te Whero Whero, was elected "king" in 1858 largely by the Waikato and Maniopoto tribes, and "reigned" as King Potatau I. This "king" movement, and also the unrest in the Taranaki headed by Wiremu Kingi (the two movements remained distinct from each other) were opposed to further land sales.

The likelihood of conflict was not reduced by any particular wisdom in government policy. Gore Browne was guided in native policy by the head of the Native Land Purchase department, Donald McLean, who, responsive to settler demands, increased pressure upon potential sellers. Grey's caution, and his recognition that a chief could veto sales proposed by any section of his tribe, were forgotten. McLean sowed a rich harvest of distrust. Christopher Richmond, the member of cabinet in charge of native affairs, was also a Taranaki representative, fully responsive to the needs of his settler neighbours. The central ministry, theoretically unconcerned with native policy, could not, despite the promise of protection made to the Maoris in the treaty of Waitangi, neglect a matter so vital to the colony's future. In 1859 the representative of the crown unwittingly supplied the occasion for the outbreak of civil strife.

Gore Browne accepted an offer to sell from a Taranaki subchief, Te Teira, and ignored the veto imposed by the paramount chief, Wiremu Kingi. Early in 1860 troops were used to dislodge Kingi from the land in question, the Waitara block. A decade of fighting began. In 1861 Grey was sent back for a second term as governor in the hope that he would again prove to be a peacemaker. In fact he accelerated the extension of conflict. Fearing that Auckland was menaced by the followers of the Maori king, he took defensive measures which could easily be interpreted as acts of aggression. Thus fighting spread from Taranaki to the Waikato. Imperial troops, colonial militia, Maori allies (for not all the tribes supported the Maori nationalist movement) had no easy task, but their victory could not be postponed for long. By the mid-1860s Maori resistance in the Taranaki and Waikato was ended. But the King tribes were by no means crushed, and the chance that they would embark upon war again haunted the colony for many years.

In the later 1860s the fighting was of a different character, in which religion acted as a last, desperate stiffener of Maori resistance. *Pai marire*, a bizarre and bloodthirsty amalgam of Christian and primitive beliefs, was the first of many cults in which the Maori, rejecting the religion of settler and missionary, put his own imprint upon Christianity. Toward the end of the decade, Te Kooti organized resistance on the east coast. He was the founder of another religious cult as well as a guerrilla of some note; his adaptation of Christianity, *Ringatu*, still had thousands of followers in the mid-20th century. Te Kooti was never finally defeated, but by the early 1870s he was forced to retreat into the "King country" (the centre of the island) where he devoted the rest of his long life to religious leadership.

An uneasy peace settled upon the colony in 1870. Casualties had not been high, but the loss of life was serious for the tribes concerned. Especially in those areas in which the Maori king retained some authority, defeat led to a sullen withdrawal from European civilization. Resentment was deepened by a punitive policy of land confiscation adopted by the victors, a policy improper in its nature and made worse in some places by undiscriminating application to "guilty" and "innocent" tribes alike. The Maori future looked black. By the 1862 Native Land act private land transactions between settler and Maori had been legalized, and during the next 40 years the Maoris lost most of their best land. Many years were to elapse before Maori numbers, morale and confidence could revive.

Development of the Colony

Economic growth in the North Island had been considerably retarded by the wars. Meanwhile, during the same period, the South Island, especially Canterbury and Otago, had grown increasingly prosperous. Pastoral farming expanded steadily and the discovery of gold, first in Otago and then on the west coast, led to a sudden boom in production and trade. Population rose as diggers poured in; economic life quickened as gold brought prosperity

less to the digger than to bankers, merchants, land sellers and farmers supplying provisions. The South Island share of the European population jumped from about 40% to 60% during the 1860s. The North Island did not recover its previous lead until the 20th century.

Attempts by other provinces to emulate the development of Canterbury and Otago normally ended in embarrassment (in one case in bankruptcy) as money was recklessly borrowed and spent. To preserve the colony's reputation the central government in 1867 banned further provincial borrowing. About the same time depression struck the greater part of the country, especially the South Island, where the first alluvial gold had by then been worked out. The South Island was thus looking for a stimulus, while the ending of the wars now made further development possible in the North Island. It was widely agreed that only the central government could adequately revitalize the economy.

In 1870 a development policy was provided by Julius Vogel (*q.v.*), the colonial treasurer who was convinced (not altogether accurately) that New Zealand was bursting with potential resources needing no more than the stimulus of capital and labour for their exploitation. He borrowed overseas capital for public works on an unprecedented scale and swelled the labour force with assisted immigrants. Not all his schemes were wisely conceived; the prosperity of the mid-1870s was more an investment boom than a solid growth of productivity. But the colony ended the decade with a doubled population (about 500,000) and the beginnings of efficient internal and external communications. Roads, bridges, railways and telegraph systems had been built, and overseas shipping services improved. Private lending agencies contributed to the boom, and in a heady atmosphere land values and interest rates climbed alarmingly. The public debt greatly increased, and many of the men who had acquired land were in desperate financial straits. Falling overseas prices for farm products (chiefly wool and wheat), a declining gold output, a cautious note in government finance, and widespread unemployment marked the 1880s. Emigrant ships discharged their passengers at ports where unemployment was already rife. There had been growth in the 1870s, but it was succeeded by a depression which lasted till 1895.

Vogel abolished the provincial governments in 1876. They had earned his enmity by refusing to allow their lands to be used as security for public works, and by blocking a forest conservation scheme. Essentially, they became outmoded when, in the early 1870s, the initiative in development passed to the central government. Provincial governments had been set up to colonize their districts; when the centre assumed this function they lost their *raison d'être*. Abolition came fairly painlessly; it was an affront more to local pride than to local prosperity. Only in Otago was there a strong attempt to resist change. Thereafter, provincial interests were long pursued by the respective delegates in the general assembly, whose achievements were in no way diminished by the lack of particularist (provincial) institutions.

The governments of the 1880s, though led by men of some ability and imagination, such as Sir Robert Stout and Sir Harry Atkinson (*q.v.*), did not deal effectively with the depression. The time-honoured remedy, spending loan money on development, was not fully given up until 1887. The basic problem was to find productive work for the country's labour force; closer land settlement was the remedy suggested in the 1880s and applied in the 1890s. Great areas, especially in the South Island, had fallen to large owners; these "monopolists" were attacked by the radicals, though probably the pastoral industry could not have been established under any other system. William Rolleston, minister of lands from 1852 to 1884, first proposed that the state should help men to become small farmers as state tenants; John McKenzie and the Liberal government applied this remedy with vigour in the 1890s. But closer settlement and intensive farming did not succeed until small farmers had a product to export and gained a good price for that product. Refrigeration and rising world prices provided the answer. It became possible in the 1880s to send to Great Britain refrigerated cargoes of butter, cheese and meat; this encouraged the spread of small-scale intensive farming.

The Liberal Era 1891–1912.—The energetic Liberal government led by John Ballance (*q.v.*) which took office in 1891 accelerated the process of change. It opened more land (much of it bought from the Maoris), it established farmers on perpetual state leaseholds, it provided generous credit for land purchase and for improvements. So came into existence great dairying and meat producing areas, especially in the North Island. Dairy, meat and also wool prices rose in about 1895 and stayed generally high until about 1920.

This economic stimulus was not limited to farmers. Urban distress had been serious in the 1880s, for many recent immigrants had been townsmen who had stayed in New Zealand towns on arrival. The ultimate cure for their distress was for the towns to share in the farmers' high prices. Urban New Zealand depended upon the prosperity of the country. But other remedies were considered, and some of them were applied. In the 1880s there was serious discussion of insurance against sickness, poverty and old age; the Old Age Pensions act of 1898 was the first measure of social security. Tariff protection to foster industrial employment was halfheartedly applied in the late 1880s. Revelations of oppression in industry led, in the 1890s, to a labour code to protect workers.

But the chief Liberal industrial policy, formulated by William Pember Reeves, minister of labour from 1892 to 1896, was to encourage trade unions and to introduce, in the Industrial Conciliation and Arbitration act of 1894, a conciliation and compulsory arbitration system intended to end industrial unrest and give the unions the means of protecting their members. The growth of unions was stimulated by the fact that only through them could the workers use the system. Reeves's act, amended and occasionally suspended, but still essentially his own handiwork, has never been repealed. It has enabled the worker in good times to resist wage cuts and to press for increases; but it has not managed to prevent cuts and unemployment when falling overseas prices have brought depression to New Zealand. It has not been strikingly radical in effect; employers and governments have used it to break strikes, such as that of miners at Waihi in 1912. It has built up the power of those majority elements in the unions which prefer coming to terms with capitalism to any effort to destroy it. Some occupations, such as transport, cargo handling, meat processing and mining, have fostered unions keen to relinquish arbitration for direct action, but they have been in a minority, and seldom, in the long run, successful. Farmers and governments have usually acted with severity in disputes affecting the movement of exports.

The Liberal era, from 1890 to 1912, transformed political life. Previously politics had not been marked by neat party divisions. Local advantage had determined political behaviour in the development period during and after the 1870s; men had argued over the scope and details of policies, and had advanced the claims of locality and province for a proper share of largesse. Acute depression ended development, and with it the politics of local advantage. In 1890 the Liberals began to act as a more or less unified party. Their 20 years in office, the success of their land and labour policies, and the formidable qualities of leadership discovered in Richard John Seddon (*q.v.*), premier from 1893 to his death in 1906, welded the Liberals into a fairly coherent parliamentary and popular party.

Seddon was a portent of a new age. In 1893 this energetic goldfields trader-turned-politician provided a sharp contrast to the gentlemanly premiers who had preceded him. But his crudeness assisted rather than hindered the attainment of a popularity none of them had known. He was devoted to political success and skilled in the manipulation of the means of success—parliamentary procedure, patronage and party organization. By the time of his death he had established a kind of elective despotism over the country.

The 20th Century

Seddon's successors, in his own and in other parties, were of the same stamp—men of the people devoted to a political career. Politics ceased to be a duty of the well-to-do amateur. The Liberal government, under Sir Joseph Ward (*q.v.*), survived Seddon

for six years. In 1912 it fell before a new party, Reform, led by a dairy farmer, William Ferguson Massey (*q.v.*), prime minister until 1925. Based on prospering farmers and townsmen, especially of the North Island, and closely connected with their professional organizations, it was more narrowly sectional than the Liberals had been. Except for views borrowed from the Liberals, it had little positive policy. Reform made much of a promise to enable the state leaseholder to buy the freehold of his farm at original valuation; this promise was an emotional rallying cry for conservatives fearing land nationalization and complete socialism. Only a minority of farmers were state tenants, and not all of these bought the freehold when the Reform government gave them the chance.

While the Liberals lost support in rural areas, they were further weakened by urban left wing defections which eventually led to a separate Labour Party. Four Labour members were returned in 1911. The initiative, on the right and on the left, was passing to other parties, and the Liberals were gradually eclipsed. The period before World War I was one of discontent and anxiety. Prosperity, though still considerable, had somewhat declined. The farmers were disturbed by what they took to be the threat of socialism, detected in the radicalism of a Liberal minority, but chiefly in the rebirth of direct action in some trade unions. This change in temper arose from labour dissatisfaction with wage levels achieved under arbitration, and from the growth of syndicalist and socialist ideas. After 1906 the Arbitration court refused to grant further increases of real wages. Discontent flared up in the strikes of 1912–13, the biggest occurring on the waterfront when the farmers' government, headed by Massey, vigorously repressed a strike movement which had some of the overtones of social revolution.

World War I and the Inter-War Years.—New Zealand supported Great Britain in World Wars I and II, chiefly by sending men overseas and producing food and wool. In World War II the Japanese brought danger close to New Zealand's shores; in the earlier conflict the peace of the Pacific was seldom disturbed.

New Zealanders served in the Dardanelles campaign at Gallipoli, and subsequently in France. In these battles they began to learn that they were a distinctive branch of the British people. The infantry "digger" of 1914–18 came to symbolize those qualities which the country most respects—courage, endurance and resourcefulness. New Zealand lost many of her young men, a serious loss for succeeding decades.

At home the war brought prosperity, as export markets were assured and prices good. Domestic unity was hardly shaken by the antiwar feeling of a handful of left-wingers. Massey remained prime minister, but in the wartime coalition government (1915–19) Ward and the Liberals carried great weight. Reform stayed in office till 1928, led after Massey's death in 1925 by Joseph Gordon Coates (*q.v.*). The party survived the first postwar depression, but not that of the mid-1920s. Led by Ward the Liberals, under the new name of United Party, were victorious in 1928; they thus had to face the deepening depression of 1929–30. After Ward's death (1930) and at the height of the depression, Reform and United formed a new coalition (1931) under the premiership of George Forbes, which lasted till an electoral landslide in 1935 brought in a Labour government.

Some postwar developments were of great importance. In external affairs, Massey led a delegation to the peace conference, signed the treaty of Versailles, and so committed New Zealand to membership in the League of Nations. New Zealand thus began to acquire the status of a sovereign state, though Massey denied this consequence. The Liberals, especially Seddon, had already taken steps toward autonomy within the empire. At the series of colonial and imperial conferences from 1887 onward, New Zealand had followed Canada and Australia in asserting its right to a voice in certain foreign policy issues. Seddon argued vehemently against British reluctance to acquire more Pacific islands, while permitting German influence to grow in Samoa. New Zealand legislation to restrict Asian emigration was sharply and obstinately at variance with British policy. Western Samoa, which New Zealand had captured from the Germans in 1914, and over which it was granted a mandate in 1920, also provided occasions for British and New Zealand differences.

Reform leaders professed little love for the principle of autonomy which, in the 1920s, came to dominate commonwealth relations. New Zealand took part in the conferences leading to the statute of Westminster in 1931, but did not adopt the statute till 1947. But the substance of autonomy had been enjoyed long before.

The major domestic achievement of the Reform administration was a system of export marketing agencies in which authority was shared by producer and state. These failed in their short-term objective—to sustain farmers' returns while prices fell—but they laid the foundations of a collectivist marketing structure which has continued to expand.

The leading domestic phenomenon was the rise of Labour. The New Zealand Labour Party was established in 1916; in the 1920s it came to dominate working class urban electorates. But complete success eluded it. It had little to offer the rural voter until 1928, when it offered easier credit, and then the revitalized Liberals (United) offered an attractive alternative quite free from the taint of extreme socialism which still clung to Labour. The United Party went back to the old remedy of massive expenditure of borrowed money. In fact the prospect of electoral success had by this time caused the Labour Party to substitute for its socialism a series of welfare and credit proposals. The formation of the coalition between Reform and United in 1931 made Labour the official opposition. Industrial labour, notably sections influenced by semi-syndicalist ideas, was a restive ally for the party. But unemployment, the suspension of the arbitration system in 1932 and a nationwide series of wage cuts drove the two wings of the labour movement together. Trade unionists had now learned that their welfare depended upon political power. Politicians could abolish arbitration, their main defense against poverty, and other politicians would be necessary for its restoration. The new solidarity played a large part in the Labour victory of 1935.

J. G. Coates was the most energetic and least conservative coalition minister. His attempts to counter depression concentrated upon the rehabilitation of the farmer as a step toward the revival of the whole country. In order to increase export receipts he devalued the New Zealand pound from £110 to £125 per £100 sterling; he protected the farmer against foreclosure, and he set up a credit agency, the Mortgage corporation. He also established the Reserve Bank of New Zealand. When overseas prices began to recover in 1934 the country was financially strong.

But he had done little for the multitude of unemployed. Unenviable conditions in towns and relief camps led to outbreaks of rioting and violence, to widespread discontent, and to the Labour victory. Successful in the towns, Labour also won in many rural areas, especially in the dairying districts. Prices for dairy exports were slowest to recover, and the dairy farmer was drawn by Labour promises of a guaranteed price for dairy produce and cheap and plentiful credit. The victory was particularly notable in terms of seats, for a right-wing third party (the Democrat Party) split the conservative vote to Labour's advantage. However, a contest in 1938 without the Democrat Party had the same result, and the opposition (the successors of Reform and United now renamed the National Party) was rendered temporarily ineffective.

The new ministers, among whom the most notable were Peter Fraser (*q.v.*) as minister of health and education, and Walter Nash as minister of finance, showing great energy and genially led by Michael Joseph Savage, had the good fortune to govern a country to which prosperity was fast returning. The farmer was enjoying increased earnings, the worker increased wages and shorter hours. Jobs were multiplied by a massive public works and housing program; attempts were made to stimulate secondary industry, and to diversify the economy to make it less vulnerable to overseas conditions. The education system was revitalized. In 1938 the Social Security act provided a state medical service, extended the pension system and increased benefits. The expansion of industry was accelerated after the outbreak of World War II in 1939.

World War II and After.—The alacrity with which New Zea-

land went to war in 1939 showed that dominion autonomy had not weakened the country's ties of sentiment with Great Britain. At first the war resembled that of 1914; troops were sent to Egypt to train for the European conflict. There they were directly involved by the enemy advance in North Africa and the Balkans, and saw action in Greece, Crete, North Africa and Italy before the final Axis collapse. After 1941 New Zealand was directly threatened by Japan, and New Zealand forces were also engaged in the Pacific. They were not withdrawn from the European fighting and well before the end of the war the double strain upon the country's manpower, together with the demands of home production, enforced a reduction of commitments in the Pacific.

The Pacific theatre was dominated by the U.S. whose forces, after the loss of Singapore (1942), provided New Zealand's sole defense. U.S. troops were stationed in New Zealand, and New Zealand forces fought under U.S. command. The fact that disaster was averted by U.S. and not by British troops imposed a certain strain on New Zealand's loyalties. For generations security had been guaranteed by British power; now it was conferred by a foreign, though friendly, power. External relations in the postwar period reflected this new situation, chiefly through the ANZUS pact (1951), a defensive alliance between Australia, New Zealand and the United States.

At home the total economy was mobilized in the war effort. Controls, already considerable by 1939, were extended to cover every aspect of economic life. Conscription and direction sent manpower either into the armed forces or to essential occupations; heavy taxation, war loans, bulk purchase, and controlled marketing kept the economy in a firm grip. These devices also served to keep inflation in check; together with price control and wage restraint they amounted to a complete policy of economic stabilization. These controls were applied by a Labour government which remained in power until 1949. Savage died early in the war. Fraser, his successor as prime minister, inherited a large share of the tasks of war administration and peacetime reconstruction. In economic affairs, the leading minister was Nash. No full coalition was formed, but for a few months in 1942 a war cabinet, on which some National M.P.s had seats, among them Coates (d. 1943) and Sidney (afterward Sir Sidney) Holland (*q.v.*), existed alongside the normal cabinet.

Holland led the revival of the National Party which was marked in the elections of 1943 and 1946 and culminated in victory in 1949. Discontent with controls and with the rising cost of living were among the factors which caused opinion to swing away from Labour. Subsequently, the two parties remained fairly evenly balanced. The National government benefited from its vigorous handling of a serious waterfront dispute in 1951, but in later elections its majority narrowed until Labour returned to office in 1957. In 1960, however, the National Party, now led by Keith Holyoake, was returned to power, which it maintained for the next two elections. By the time of the 1966 election the ideological differences between the two parties had narrowed. That the economy had to be controlled, secondary industry encouraged, and the welfare state maintained ceased to be matters for debate. But the nation's prosperity was precarious, and this led, especially in rural areas, to the emergence of a Social Credit movement, which in 1966 won its first parliamentary seat.

The most striking postwar development took place in international affairs. Not only did the U.S. come to supplant the U.K. in New Zealand's thinking about military security, but also New Zealand began to play a relatively independent role in world politics. This latter development in fact began before World War II, when the Labour government's attitude to the League of Nations was coloured by an idealism which clashed with prewar British policy, especially over the Ethiopian issue. This independent spirit was carried by Fraser to the formation of the United Nations organization. During the war Fraser had insisted upon an independent voice in the councils of the Allied powers, especially where the fate of New Zealand troops was concerned. At the formation of the United Nations at San Francisco in 1945 he became a notable spokesman for the small powers and made a large impression upon the deliberations of the Trusteeship council. None of these developments weakened New Zealand's close affinity with Great Britain, nor its loyalty to the Commonwealth of Nations. Independence and close identity were found to be compatible.

Geography and insecurity shaped New Zealand's postwar foreign policy. With Australia, New Zealand claimed a voice in the settlement of the South Pacific through the Canberra Agreement of 1944. This regional concern also appeared in its role in the South Pacific Commission, and in the transfer of authority in Western Samoa, successfully completed when that country became independent in 1962. New Zealand also became deeply involved in Southeast Asia. From 1951, through the Colombo Plan, it provided assistance to many Southeast Asian countries. More militantly, New Zealanders fought in Malaya, Korea, and Vietnam; further, New Zealand became a member of the Southeast Asia Treaty Organization (SEATO) and supported U.S. initiatives in that region. This reflected the fear felt at the growth of Communist power in Asia. Thus the independent spirit of the immediate postwar years was modified to a greater dependence on Western powers during the 1950s and 1960s.

Two major social problems confronted New Zealand in the second half of the 20th century: to find a productive occupation for a growing population, and to preserve harmonious relations between the two races. The country was still an exporter of primary products and an importer of manufactured goods and industrial raw materials. But farming absorbed a decreasing share of the labour force, and traditional farm exports and their markets proved less reliable. To maintain full employment and to strengthen exports, the country began to diversify at home, to explore new products, and to seek new markets. The threat of British entry into the European Economic Community (Common Market) was an incentive to economic reconstruction.

The Maori population had been increasing with greater speed than the total population, and a great number of Maoris, especially younger people, had moved into the towns. In the 1950s the government began an effort to raise the economic and social standards of the Maoris. By the 1960s their standard of living was not yet, on the average, comparable with the European standard, and forethought was necessary to secure the harmonious integration of the two races. Full legal equality existed, and social harmony was common. But there were instances of prejudice and discrimination. In the long run the solution to the problem may be found in the merging of the two races. (W. H. OL.)

III. POPULATION

Since the European settlement of New Zealand in 1840, the white population has risen from about 1,000 to 2,676,919 (1966 census, excluding island territories). The two significant population trends have been the increasing proportion resident in the North Island—a reflection of the markedly different range of resources available in the two islands; and the increasing urbanization—a reflection of the changing character of the economy. The existence of land suitable for sheep grazing and the discovery of gold initially favoured the settlement of the South Island, which by 1871 contained 62% of the 256,393 white inhabitants. But the ascendancy of the North Island was assured by the establishment of dairying and fat-lamb farming upon the huge tracts of forest land which had been cleared. The mounting contribution made by manufacturing industry to the economy during the period 1930–60 underlined this superiority. In 1966, 70% of the population resided in the North Island. With 70% of the workers engaged in manufacturing, the North Island was dominant also in the industrial sector, the Auckland employment district alone accounting for 28.5% of the total employed.

Although New Zealand is primarily a pastoral country, earning overseas exchange almost wholly by the sale of pastoral produce, it has a highly urbanized society, and only 17% of the total labour force is engaged in primary industries. In 1911 the population was divided equally between rural and urban districts but at the 1961 census 63.6% were classed as urban dwellers, though 70% would have been a more realistic figure. The principal urban areas are Auckland (*q.v.*; 548,293), Wellington (*q.v.*; 167,859) and Hutt (114,628) in the North Island; and Christchurch (*q.v.*; 247,248)

Area and Population of New Zealand

Statistical Area	Area (sq.mi.)	1956 Census	Density	1961 Census	Density
Northland	4,883	83,330	17.1	86,391	17.7
Central Auckland	2,155	441,069	204.7	514,507	238.8
South Auckland Bay of Plenty	14,187	302,304	21.3	349,624	24.6

and Dunedin (*q.v.*, 105,003) in the South Island. Thirteen other urban areas had populations exceeding 20,000, of which Hamilton (*q.v.*, 50,505) and Palmerston North (*q.v.*, 43,185) were the largest.

The vital statistics of the European population display the trends common to the western countries. The death rate and the infant mortality rates have shown constant decreases, except for a slight increase in death rate since 1946 attributable to the aging population. The death rate per 1,000 of population is 9.0. From a peak of 41 births per 1,000 in 1876 the birth rate gradually decreased until it reached its lowest point in 1935 with 16. Following World War II the rate remained fairly stable at 24–25 births per 1,000. Combined with immigration, which over the period 1956–61 gave an average net increase exceeding 11,500 annually, this rate produced during the 1950s an average annual increase of 2.3%, one of the highest in the world.

The Maoris.—Susceptibility to European diseases and the social disorganization resulting from European contacts caused the Maori population to decline from 56,049 in 1857 to 42,113 in 1896. Thereafter it increased; and did so spectacularly after the 1920s. In 1921 Maoris numbered 56,987; by 1961 there were 167,086, but they represented only 6.9% of the total population. Following World War II the Maori birth rate remained at the high level of 46 per 1,000. The death rate declined considerably in the first half of the 20th century and now compares favourably with that of the Europeans. But the Maori infant mortality rate (44.5 per 1,000 births) is higher than the European (19.7) and the favourable death rate is markedly influenced by the youthful character of the Maori population as a whole. Thus while 47% of the Maoris are under 15 years of age the corresponding figure for the European population is 30%. Similarly, persons of 60 years of age and over account for 13% of the European and only 3½% of the Maori population.

Few Maoris dwell in the South Island. Most live in the more northern parts of the North Island, especially in the Auckland land districts. The Maori population remains largely rural in character (76.23%) and consequently most Maoris are employed in the primary industries. Urban drift is apparent, especially among the younger Maoris, Auckland with 19,847 Maoris in 1961 being the main centre of attraction. In 1926, 3,457 Maoris lived in towns; by 1961 the Maori population of the major urban areas had reached 55,681. The department of Maori affairs estimated that intermarriage was responsible for reducing the proportion of full-blooded Maoris to 20% of the total Maori population. (*See* also MAORI.)

Population Totals.—The total population, Maoris included, at the following census dates, was: 1858, 115,462; 1881, 534,030; 1901, 815,853; 1921, 1,271,664; 1936, 1,573,810; 1951, 1,941,366; 1956, 2,176,224; 1961, 2,414,984. The population of the island territories at the census of 1961 was 25,252 and that of the trust territory of Western Samoa (which became an independent state in 1962) was 114,427.

Immigration.—Persons wholly of British birth and parentage or wholly of European race and colour are given verbal permission to enter New Zealand on arrival, subject to good health and character and possession of a valid passport. Such immigrants do not need written permits, visas, guarantees of work nor any prescribed sum of money. Other categories of immigrants require written permits from the immigration division of the department of labour.

The New Zealand government in 1947 introduced an assisted passage scheme for single persons from the United Kingdom aged 20–35. In 1951 the scheme was amended to include single persons up to age 45, certain categories of married British immigrants and, after the conclusion of agreements with the countries concerned, of a number of non-British single men and women. In the period 1946 to March 1962, 58,783 migrants settled under these schemes and 274,070 unassisted migrants took up permanent residence.

Religion.—According to the 1961 census, the adherents of the main denominations were distributed as follows: Church of England 34.6%, Presbyterian 22.3%, Roman Catholic 15.1%, Methodist 7.2%. Of the overwhelmingly Maori Christian sects Ratana (23,126 adherents) and Latter-day Saints (17,978) were the strongest.

In 1857 the Anglican Church of the Province of New Zealand was inaugurated in full communion with Canterbury. Government is by a general synod, which elects the archbishop-metropolitan or primate from among the diocesan bishops; thus the primate's see is not fixed in any one city. There are nine dioceses (including two with jurisdiction over Melanesia and Polynesia) and a separate bishopric (Aotearoa) for the Maoris. The Roman Catholic Church is organized in three dioceses subject to the archiepiscopal see of Wellington. (S. H. F.)

IV. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution.—New Zealand was constituted a dominion in 1907. Although the Statute of Westminster (1931) was not formally adopted until 1947 by the New Zealand parliament, the dominion had freedom to conduct both its internal and external affairs as it saw fit. In accordance with parliamentary legislation Queen Elizabeth II was proclaimed in Wellington on May 29, 1953, "by the Grace of God, of the United Kingdom, New Zealand and her other Realms and Territories Queen, Head of the Commonwealth, Defender of the Faith." This now declared the British monarch's specific and separate sovereignty over New Zealand, as also over other commonwealth realms. The sovereign is represented by the governor general, whom the former appoints after consulting the New Zealand government. Representing a constitutional monarch, the governor general must be guided by the advice of the New Zealand cabinet; while he does not "govern" and his functions are formal, his signature affixed to an act of parliament or order in council expresses legislative or executive decision.

2. Central Government.—There were in the early years six distinct settlements—Auckland, Wellington, Nelson, New Plymouth, Canterbury and Otago—between which communication was for long irregular and infrequent. To meet their political needs the Constitution act of 1852 made them into provinces, with elective councils and superintendents subordinated to one colonial legislature. In 1876 the provincial system was abolished and full control passed to the legislature, usually known simply as parliament, which consisted of the legislative council (the upper house) and the house of representatives (the lower house). The members of the legislative council were appointed for seven years by the governor general on the advice of the cabinet. Women became eligible for appointment in 1941. As in the case of the United Kingdom house of lords, the legislative council could not initiate or amend taxation and revenue bills, and most legislation was first introduced in the lower house. In 1951, however, the legislative council was abolished.

The house of representatives has 80 members, four of whom are Maori. After each population census the 76 European electorates are readjusted according to population distribution, and following the 1961 census there were 52 European seats for the North Island and 24 for the South Island. In 1937 the normal life of parliament was fixed at three years. Women became eligible as members in 1919 and public servants in 1936, the latter with the provision that if elected they immediately ceased to be public servants. An elector must be a British subject resident for one year in

New Zealand and for three months in the electoral district in which he claims to vote.

Registration became compulsory in 1924. The Electoral Amendment act of 1937 introduced a secret ballot for Maori voters, who enjoy the same electoral privileges as non-Maoris in electing the representatives of the four Maori electorates. In 1948 a further amendment was made to provide for the registration of Maori voters.

Executive administration is conducted on the principle of the British parliamentary system, that is, executive power is vested in a cabinet (the members of which, with the governor general, also constitute the executive council) responsible to the elected legislature—the house of representatives. The cabinet, chosen from members of the majority party in the house, consists of the ministers or "political heads" of departments of the government. The Maoris are usually represented by one member in the cabinet. Members of the house of representatives are paid.

3. Local Government.—With the abolition of provincial administration in 1876 (*see* above) the dominion was divided into 63 counties, with provision for elective councils to deal with such primary needs as road and bridge building. For local administration the 63 counties were later subdivided into 121 and, in addition, there were 143 borough councils (for areas not greater than 9 sq.mi. having a population of at least 1,500), 11 dependent town districts (where there were 50 householders in an area of not more than 2 sq.mi.) and 15 independent town districts (having a population of 500). Besides the 121 counties, and the boroughs and independent town districts within them forming separate administrative entities, there were numerous autonomous, overlapping districts formed from parts of counties (concerned with roads, drainage and rivers) and others made up of groups of adjacent districts

ADMINISTRATIVE LAND DISTRICTS OF NEW ZEALAND

of other types united for a common purpose. By 1962 there were 952 local authorities functioning.

The provincial districts of Auckland, Hawke's Bay, Taranaki and Wellington in the North Island, and Canterbury, Marlborough, Nelson, Otago and Westland in the South Island are merely historic divisions which serve as convenient units for a primary geographical breakdown. The 12 land districts into which the country is divided for the administration of crown land correspond to the provincial districts except that Auckland is split into North Auckland and South Auckland, Hawke's Bay into Hawke's Bay and Gisborne, and Otago into Otago and Southland. *See* separate articles on the districts.

4. Political Parties.—After the coalition in 1931 of the Liberals and Reformers, only two parties were represented in parliament: the Labour party; and the National party. Other parties, such as the Social Credit party, contested elections but failed to gain representation. The Labour party, like its counterpart in the U.K., derives its strength chiefly from trade unionism and the urban industrial electorate, while the National party depends mainly on rural interests, merchants and employers. But the policies of both parties make it necessary for them to win the support of a large middle-class element. The parties base their policies and programs largely on annual conferences attended by their members of parliament and by the district representatives of the party organizations. (W. B. Pn.; A. T. Cl.)

5. Labour Legislation.—As a result of the legislation of the Liberal government which came into power in 1891 New Zealand acquired world fame as a land of advanced social legislation while still in the pioneer stage of economic development. The labour code, established principally by the Industrial Conciliation and Arbitration act of 1894, provided for the settlement of industrial disputes by judicial means and not by strike action and enabled working conditions to be modified to meet changes in the economy without constant recourse to acts of parliament. The system of compulsory arbitration was modified to the point of abolition during the depression of the 1930s. It was restored by an amending act of 1936 which also empowered the court to fix basic wage rates for adult workers and, where practicable, to fix the work week at 40 hours (exclusive of overtime). Union membership was made compulsory until 1961, when the legislation was modified. During World War II strikes and lockouts were illegal. The position of the unions is also regulated by the Trade Union act of 1908, largely based on the corresponding British act of 1871. The unions that have exerted the greatest pressure are those of the transport workers, miners, seamen and waterfront workers. As a result of the serious waterfront strike of 1951 legislation was passed to ensure democratic control of unions. It provided for the election of officials by secret postal ballot and gave the state power to require a secret ballot to be taken at any stage during a strike. After 1944 all workers had a minimum paid holiday period of 14 days annually.

6. Social Security.—New Zealand's Old-Age Pensions act (1898) was the first such measure in any British country. Widow's pensions were introduced in 1911; pensions were granted in 1915 to miners incapacitated through miner's phthisis or other occupational disease; in 1926 allowances were granted to families having more than two children and limited incomes; blind persons and chronic invalids also received pensions. The Social Security act of 1938 increased the rates of the various noncontributory civil pensions and placed them on a universal contributory basis. It also introduced a universal superannuation scheme under which benefits were paid irrespective of income received or property owned. In 1945 family benefits were made payable for each child irrespective of income or number of family. In 1948 many New Zealand social security benefits were put on a reciprocal basis with those in Australia and family benefits only were made reciprocal with the United Kingdom. A reciprocal agreement for other benefits took effect from April 1, 1956. New Zealanders pay 1*s.* 6*d.* in each £1 of income to the Social Security fund which is also supplemented from general revenue.

Hospitals and Health.—Before 1938 the expenses of hospital boards were met by payments from local ratepayers, government

subsidies and contributions from those patients who were able to pay. By the Social Security act the responsibility for the patient's share was transferred to the Social Security fund. The contribution of local ratepayers was reduced in the mid-1950s and after 1958 the entire cost was borne by the state.

Under the social security scheme every person is entitled to medical treatment. Medicines prescribed are free. Maternity benefits include antenatal and postnatal advice and treatment, attention at confinements and treatment and maintenance in hospital. In private hospitals part of the fee for treatment and maintenance is covered by the Social Security fund.

Housing.—Through the state advances department, created in 1894, the government lent money for the purchase of homes and the improvement of farms. In 1934–35 the department was reconstituted as the Mortgage corporation, some private share capital being subscribed, but in 1936 the State Advances corporation was founded, with the elimination of private share capital and the liberalizing of advances. The government undertook direct home building in 1937. While actual erection was by private builders the purchase of land and the designing and letting of houses were carried out by the state. From 1950 tenants were given the opportunity of purchasing these state houses. The housing shortage became acute during World War II and continued after the war.

7. Justice.—The chief justice of New Zealand and a number of puisne judges constitute the supreme court and court of appeal. There are also three special courts—arbitration, compensation and land valuation. Magistrates' courts have both civil and criminal jurisdiction, but more serious criminal cases are not tried summarily but are sent to the supreme court for trial or sentence. Maoris may use their own language in court. The police force, which is a national organization, and the national police training school are maintained wholly by the central government. In 1962 New Zealand appointed its first "ombudsman," an official who examines complaints against the state.

8. Education.—The Education act of 1877 made state education in New Zealand free, secular and compulsory between the ages of 7 and 14 (in 1944 raised to 15). It is controlled by a state education department and local education boards.

Kindergartens.—Children between the ages of three and five may be enrolled at free kindergartens maintained by the Free Kindergarten association. The government makes annual grants toward the support of the kindergartens, but the system is far from universal. In the 1960s there were about 15,000 children on the rolls in about 200 free kindergartens.

Primary Schools.—Entry to primary school is permissive from the age of five. All state primary schools are coeducational. The syllabus of instruction includes elementary science, agriculture and cultural subjects. Older boys receive instruction in woodwork and metalwork at manual-training centres, and older girls are taught domestic subjects. In country districts where the numbers do not warrant separate secondary schools, older pupils attend district high schools, which are under the same control as the primary schools. In addition, intermediate schools provide varied and enriched courses for older children to help them decide on their lines of further education.

Postprimary Schools.—In 1936 free postprimary education to the end of the year in which he is 19 was offered to every child completing a primary-school course or attaining the age of 14. About 94% of children leaving public primary schools proceed to full-time postprimary schooling. Postprimary (secondary) schools are termed grammar schools in Auckland, colleges in Wellington and high schools in the North Island and over most of the South Island. A secondary and a technical school amalgamated under a single governing body is known as a combined school. Technical schools fall roughly into two types: those in the small centres distinguishable from secondary schools only by a more strongly developed practical side; and large technical schools in the main centres—where city secondary schools provide an academic curriculum. In 1938 the government assumed responsibility for vocational guidance at postprimary schools.

Rural Education.—Country children, as far as practicable, receive the same educational facilities as town children. Small rural schools have been consolidated and school buses or free railway passes are furnished. Correspondence classes are conducted for those in remote areas, and broadcasting is much used. Country teachers are better paid, and every city teacher, to qualify for promotion, serves three years at a country school. The teaching of agriculture is a special feature in rural schools, and projects are undertaken by boys' and girls' agricultural clubs.

Private Schools.—In 1922 registration of private schools was made compulsory and standards of efficiency and suitability were imposed. The majority of the private primary schools are conducted by the Roman Catholic Church. That denomination and the Anglican and Presbyterian Churches maintain their own secondary schools, generally boarding establishments. Some of the private secondary schools are endowed and run on English public-school lines and the headmasters of some of the boys' schools belong to the Headmasters' Conference of Great Britain. Of such schools Christ's college, Christchurch (1850), is the oldest. Others are King's college, Auckland (1896), and Wanganui Collegiate school (1854).

Maori Education.—In 1879 the department of education took over direct control of Maori education. The system has contributed much to the progress of the Maoris. More than half the Maori children attend public schools with white children. The remainder attend Maori schools which number about 150, with a primary enrollment of about 12,000. Maoris are entitled to free secondary education in postprimary schools and in the 11 Maori secondary schools and to postprimary education of a practical nature in 10 Maori district high schools. The Maori has complete equality in citizenship with Europeans and a time can be foreseen when Maori schools will be absorbed by the general system.

Higher Education.—The University of New Zealand, founded 1870 as an examining body and refounded 1926 as a federal university with constituent universities and university colleges, was dissolved by act of parliament effective Jan. 1, 1962, and its constituent institutions became autonomous universities: University of Auckland (1882), Victoria University of Wellington (1897), University of Canterbury (1873) at Christchurch and University of Otago (1869) at Dunedin. Although each provides the customary degree courses in arts and science, Auckland specializes in architecture, engineering and fine arts; Victoria in political science, public administration and social science; Canterbury in engineering and fine arts; and Otago in medicine, dentistry, home science, mining and physical education. The two agricultural colleges that had been associated with the University of New Zealand became university colleges of agriculture: Lincoln college (1878) became a constituent college of the University of Canterbury; Massey University College of Manawatu, at Palmerston North, founded 1963 by merger of Massey College (1926) and Palmerston North branch of Victoria University of Wellington (1960), became associated with Victoria. An extramural branch of Auckland became independent in 1964 as the University of Waikato.

Adult Education.—The Workers' Educational association was the pioneer of adult education classes, working with the then university colleges through tutorial classes. A National Council of Adult Education supervises grants to the university areas where local directors of adult education organize adult classes in a variety of subjects. Similarly, postprimary schools extend the night classes to cover nonvocational subjects.

Educational Research.—With the financial assistance of the Carnegie Corporation of New York, the New Zealand Council for Educational Research was founded in 1933, given statutory existence in 1944 and since 1945 has received government support. Research is also fostered through the assistance of traveling grants under schemes provided by the Imperial Relations trust of the United Kingdom and the U.S. Fulbright grant scheme.

9. Defense.—In the South African War of 1899–1902 New Zealand sent ten contingents of mounted rifles numbering 6,495 officers and men. In 1909 compulsory training in peacetime was introduced and in 1914 New Zealand joined in World War I. A total of 98,950 men went overseas, serving in many parts of the world, notably at Gallipoli (where the title Australian and New Zealand Army corps was condensed to the famous "Anzac") and

in France; 16,697 lost their lives on active service.

Compulsory military training in peacetime was suspended in 1930 and New Zealand faced the beginning of World War II with a voluntary territorial force together with the New Zealand division of the Royal Navy (established 1920) and the Royal New Zealand Air Force (established as a separate service in 1937).

World War II.—New Zealand immediately joined the United Kingdom when Germany attacked Poland. In June 1940 both home and overseas service were put on a compulsory basis. The New Zealand second division (as the new expeditionary force was called) suffered severe casualties in 1941 in Greece and in Crete where the defense of the island was entrusted to its commander, Maj. Gen. B. C. (later Lord) Freyberg. Later in the year the division took part in the advance into Libya. In June 1942 it played a decisive part, at Minkar Kuaim, in stemming the Axis advance into Egypt. It was an assaulting division at El Alamein and was prominent in the pursuit of the Axis forces until their surrender in Tunisia. In Oct. 1943 the division crossed to Italy where it saw further hard fighting—particularly at Monte Cassino—until the end of the war.

The 3rd division, formed for action in the Pacific, took part in operations in the Solomons. The New Zealand naval forces (designated the Royal New Zealand Navy in 1941) took an active part in hostilities from Dec. 1939 when the New Zealand cruiser "Achilles" joined in the battle of the River Plate against the German pocket battleship "Admiral Graf Spee." Seven squadrons of the Royal New Zealand Air Force served in Europe with the R.A.F. and 26 with the U.S. forces in the Pacific. In all, 135,000 New Zealanders served overseas, 10,130 were killed, 19,345 wounded and 8,086 taken prisoner. Although conscription did not apply to the Maoris, 7,000 of them served voluntarily.

Apart from its fighting men, New Zealand's main contribution was in the maintenance of supplies of meat and dairy produce on which the U.K. depended. To assist the large U.S. forces stationed in New Zealand and elsewhere in the Pacific from 1942, substantial assistance was given by New Zealand under reciprocal aid both in defense construction and the supply of foodstuffs.

Postwar.—In 1949 all male New Zealanders were made liable for a 14-week period (altered to 10½ weeks in 1956) of military training on becoming 18, followed by 60 days' service over the next three years. The introduction of compulsory training made possible the organization and training of a division in peacetime.

In fulfillment of its obligations under the United Nations charter New Zealand sent troops and warships to join the United Nations forces in Korea. New Zealand also supplied some officers for the Fiji military forces. Following the Southeast Asia Defense treaty of Sept. 1954 and the commonwealth prime ministers' conference of Jan. 1955, there was a redirection of New Zealand's defense effort, when the country's commitments in the middle east were transferred to the southeast Asia area.

In 1958 compulsory military training was abolished but in 1961 a form of selective national service for the army was reintroduced. Close co-operation on defense existed between New Zealand, Australia, the U.K. and the U.S. In the mid-1960s a small New Zealand force was serving in Malaysia. (A. T. Cl.)

V. THE ECONOMY

A. Production

The economy of New Zealand is extremely dependent on specialized production, especially of primary products, on their disposal overseas and on the large volume of maritime commerce entailed. The thriving trade is the basis of the high standard of living.

During the 1950s the net value of output of the primary-produce processing and other manufacturing industries exceeded that of the farming industries. By 1960 the former represented more than 20% of net national income at factor cost. Employment statistics suggest that agriculture and manufacturing are of about equal importance in the economy: more than a quarter of all those in active employment (23% of them females) are employed in manufacturing; 16% are employed in the primary industries (about 14% in agriculture and livestock production and the rest in forestry, fishing, hunting, mining and quarrying). Nearly 60% of the population are engaged in building and construction, transport, trade and commerce and services.

1. Agriculture.—New Zealand has essentially a pastoral agriculture, based primarily on introduced pasture grasses, the maintenance of productive swards and the support of large numbers of domestic livestock. No other country has so swiftly and so completely and successfully been converted from a pre-European forested land into a land of productive pasture. No other country has nearly so much livestock in relation to its human population.

Of the total area of 66,390,700 ac. of New Zealand proper (including the minor islands) 43,666,746 ac. are in occupation (excluding land within borough boundaries and in holdings of less than 10 ac.). Of the occupied area, more than 21,000,000 ac. are in cultivation, including nearly 19,000,000 ac. in sown grasses and clovers used for grazing, hay, seed or silage. Of 23,316,416 ac. of unimproved occupied land, more than 13,000,000 ac. are in native tussock and other grasses, much of it used for grazing. Thus almost 70% of the occupied land (45% of the total area) is devoted directly to the support of livestock. In addition much of the arable crops is used to feed livestock. Less than 1% of the occupied land is devoted to cereal crops; less than 2% to green, root and other fodder crops; and only 16,000 ac. to orchards. In addition, nurseries and market gardens and specialized crops (grapes, hops, passion fruit, etc.) take 17,000 ac. and private gardens 80,000 ac.

Although the acreage of farmland occupied and of sown grasses and annual crops changed little after 1900, the number of sheep and cattle (though not of pigs and horses) increased remarkably, indicating the improved carrying capacity of farmland. Dairy cows increased from 634,000 in 1911 to about 2,000,000 in the 1960s, and sheep from 24,000,000 to nearly 50,000,000. The growth of livestock thus kept pace with the growth of human population but the carrying capacity of the land was doubled. No more men are employed on the land to handle twice the number of sheep and three times the number of cattle kept in 1911. Of importance in this increasingly efficient farm production have been a high degree of specialization; the lavish use of artificial fertilizers (especially lime and superphosphates); the breeding of new and improved grasses and clovers; the discovery and elimination of soil deficiencies; careful selection of breeding stock for performance rather than appearance; the emphasis in pasture management on intensive rotational grazing practices; careful conservation of surplus spring and early summer herbage by the mechanized making of hay and silage; and, latterly, the widespread use of aircraft for top dressing with artificial fertilizer, especially of inaccessible hill-country pastures.

Intensive dairy farming on single-family farms of 75–100 ac. closely subdivided, usually in mild, coastal areas and at lower elevations, is characteristic of the North Auckland peninsula, the Waikato, the Bay of Plenty, Taranaki and parts of the Manawatu. Most dairy cows are grade (nonpedigree) Jerseys. Annual exports of dairy produce are about 160,000 tons of butter, 100,000 tons of cheese and 75,000 tons of processed milk products (dried milk, casein, etc.).

Farms with emphasis primarily on breeding and rearing sheep are fewer, much more variable in size and generally much larger than dairy farms. They occur in all occupied portions of the country: in the windswept, peaty Chatham Islands, in the tussock alpine high country of the South Island, on the deforested and fast-eroding hill country inland of Poverty bay and on the subtropical, winterless gumland soil of North Auckland. The fattening of prime "Canterbury lamb" may also be practised on dairy farms. The tussock grazing lands—crown leaseholds—are often held in blocks as large as 50,000–80,000 ac. and carry 10–20 fine-wooled sheep per 100 ac. Typically North Island hill country, on which pastures of rye grass, browntop or the native danthonia and white clover have replaced the indigenous bush, is subdivided into farms of 500–5,000 ac. and carries Romney flocks, reared for both wool and meat, at a density of 1–5 ewes per ac.

The Canterbury plains and downland and parts of east Otago

and Southland—drier leeward South Island situations—have characteristically a mixed crop and livestock farm economy in which some combination is made of cash crops (wheat, oats, barley, peas, flax and grass and clover seed), fodder crops (turnips, lucerne, chou moellier, lupins, rape) and rotational pastures, either for grazing a ewe flock, for fattening store lambs or for the support of a small dairy herd (especially in Southland).

Fruit growing and horticulture, overshadowed by the large-scale export farm activities, have in favoured localities proved successful. Abundant sunshine and economic factors (including transport costs and access to internal markets, processing factories or ports) explain the prominence of Hawke's Bay (Hastings), Nelson, central Otago and the suburban districts. About 2,000,000 bu. of apples and pears are exported annually and following World War II there was a remarkable expansion in the canning, preserving and quick-freezing of both fruit and vegetables.

2. Forestry.—The forest industries are of growing significance to the economy and are based on two distinct types of forest—the remnants of the indigenous forest ("bush") and the planted exotic forests. The scattered acres of indigenous forests contain little tall and millable timber and are suitable only for regulating stream flow and erosion control. The exotic plantations of nearly 1,000,000 ac. are concentrated largely on the volcanic plateau in rapidly maturing stands of Monterey pine (*Pinus radiata*) and other North American conifers planted mostly between 1926 and 1935. Kaingaroa state forest (260,000 ac.) is claimed to be the world's largest artificial forest. It was planted with conifers in the 1920s–1930s on infertile pumice soil in the centre of South Auckland. Exotics account for nearly two-thirds the annual cut and the proportion is increasing. Numerous small and often temporary mills handle the cut of indigenous timbers, while a few large units cutting 20,000,000 board feet annually process the exotic cut.

Timber resources assumed vastly increased importance with the establishment in South Auckland between 1939 and 1959 of modern integrated pulp and paper industries. These have brought new communications and towns to a region long neglected, and contribute significantly to New Zealand's economy. By the 1960s timber products ranked as important in New Zealand's exports as the traditional product, cheese.

3. Fisheries.—New Zealand has a long coastline but a small and narrow coastal shelf. Much of the west coast is exposed and has few sheltered harbours. Fishing is done chiefly from east-coast ports (Auckland, Thames, Timaru, Gisborne, Napier, Wellington, Kaikoura, Lyttelton, Akaroa and Bluff) and off eastern shores. Most fish is caught in shallow water by motor trawlers. The most important of the wet fish caught are Australian snapper (*Chrysophrys auratus*), tarakihi (*Cheilodactylus macropterus*), hapuku (groper, or *Polyprion oxygeneios*), blue cod (*Parapercis colias*), flounder and gurnard. Crayfish, oysters, whitebait and whales assume economic importance. A shore whaling station operates in Tory channel (Queen Charlotte sound) and crayfish tails, exported to the United States, are a significant dollar earner. The east-coast waters of the North Island are renowned for big-game fishing and Lakes Taupo and Rotorua for brown and rainbow trout which were successfully introduced.

4. Mining.—To the Maoris, nephrite (greenstone) and obsidian were the most important minerals. In the period of European settlement first gold and then coal proved of outstanding significance. Gold provided capital and attracted population for the development of the country. Coal, even in the days of large hydroelectric plants, continues to supply a significant but declining proportion of the energy required. Important reserves include manganese, tungsten, uranium, titanium ironsands and bauxite clays. The ilmenite sands on the west coast of the South Island are estimated to contain 43,000,000 tons of ilmenite, and the black iron sands on the Taranaki and Auckland coast as far north as the Manukau river are estimated to contain 800,000,000 tons of titanomagnetite assaying at 50–59% iron and 5–10% titanium. About 3,000,000 tons of coal are produced annually, mainly on the Waikato, in Westland and in Southland. Gold production is declining and annual output is only about £N.Z. 350,000.

5. Power.—Mountainous, well watered and favoured with natural lake reservoirs, New Zealand is generously provided with water power and with suitable sites for generating hydroelectric power. But such sources are badly distributed, with the greatest potential in Fiordland and the Otago-Southland lake district while the main demand comes from the populous northern half of the North Island. Petroleum production is negligible, so that petroleum figures prominently among the imports of a country which in relation to population has more oil-burning motor vehicles than all except two other countries. Coal remains an important source of energy—especially for industrial and domestic use, and for gas and by-product manufacture. The 1950s saw the harnessing of underground sources of geothermal steam for electric power generation at Wairakei in the thermal belt of the North Island.

Hydroelectric generating stations are owned and operated by the government, which supplies power in bulk to regional and urban public supply authorities. In the 1960s the installed capacity of the government hydroelectric stations totaled nearly 1,500,000 kw., more than half of it on the Waikato river, and two-thirds in the North Island. Electricity generated for public supply totaled almost 9,000,000,000 kw.hr. or about 3,500 units per head of population. This is a high figure in view of the limited development of heavy industries, and in fact two-thirds of the consumption is not in factories but in homes and on farms. Domestic demand alone takes almost 50% of the supply, most of it for water and space heating.

In the early 1960s tests at oil wells drilled near Kapuni in Taranaki confirmed the existence of a natural-gas reservoir estimated to be capable of yielding about 100,000,000 cu.ft. of natural gas daily. Distillate from the gas was to be refined at Whangarei. If gas could be piped to Wellington and Auckland it was expected to meet half New Zealand's needs.

6. Industries.—Industrial development in New Zealand has long been hampered by the small size of the market, the lack of basic raw materials, successful competition from overseas, the ease of importing in exchange for primary-product exports and the availability of return shipping space for manufactured goods.

World War II and the shortages it occasioned stimulated industrial output. Encouraged by government policy, monetary exchange controls, import licensing, the development of hydroelectric resources, the immigration of skilled workers, the influx of overseas capital, the growth of the internal market (both in wealth and in size), the growing tendency to process primary products before export, the availability of new raw materials like softwood timber and domestic pulp for newsprint manufacture, factory industries made such strides in the period 1940–60 as to surpass primary industry both in general economic importance and in the numbers employed. Although during the period the population increased by nearly 50%, the volume of industrial production increased nearly threefold and its employees doubled in number. This development relied increasingly on imported raw or partially processed materials. But manufacturing is still organized on a relatively small scale. Nearly two-thirds of the 9,000 manufacturing establishments had individually ten workers or fewer in the 1960s, when manufacturing industries absorbed 190,000 persons (including 48,000 females) out of a total employed population of 900,000. Farming and other primary industries then employed 144,000 persons. Industrial employment is distributed among the urban centres approximately in proportion to total population, with the largest single concentration in Auckland.

The most important are the food industries, including meat freezing and preserving and butter, cheese and other milk-product manufacturing. These employ nearly one-fifth of those engaged in manufacturing and contribute nearly 40% of value of manufacturing output. In numbers employed other industries rank in the order: transport equipment assembly and repair; clothing and footwear; machinery; timber products (excluding furniture); printing and publishing; and mineral products. (K. B. C.)

B. Trade and Finance

New Zealand has always depended on overseas trade for its development; about 30% of the national income is derived from exports. Although secondary industries play an increasing part, ...

main exports continue to be agricultural and pastoral products—a development that began toward the end of the 19th century with the introduction of refrigerated shipping. The value of total trade per head of population is among the highest in the world, amounting to about £N.Z.250 (exports and imports combined) in the 1960s.

New Zealand is thus particularly sensitive to changes in world economic conditions. Prosperity largely depends on export and import prices, which are determined by market conditions outside New Zealand. Moreover, exports are confined to a relatively narrow range of products which are subject to considerable price fluctuations. Export prices have sometimes dropped 15–20% in one year, thus necessitating a corresponding reduction in imports, though the reduction may be tempered by drawing upon external exchange reserves or by temporary overseas borrowing.

1. Imports.—More than 80% of New Zealand's imports normally consist of articles wholly or mainly manufactured, a large proportion of them being goods (such as vehicles and tractors) that could not be produced economically in the country. In addition, many imports of manufactured or semimanufactured goods form the raw material of further factory processes in the country (*e.g.*, cotton piece goods). The principal imports are textile piece goods and drapery, metals and machinery, sugar, tea, alcoholic liquors, tobacco, paper and stationery, oils, motor vehicles and accessories, chemicals and drugs and manufactured fertilizers.

Most of New Zealand's imports come from the more highly industrialized countries, nearly 40% coming from the U.K. The next most important suppliers are Australia, Asian countries, the U.S. and European countries.

Customs Tariffs.—New Zealand is a moderate tariff country and about half its imports enter free of duty. Customs tariffs maintained are a general tariff, a most-favoured-nation tariff at lower rates, and preferential tariffs at still lower rates applying to imports from Commonwealth of Nations countries. The preferential tariff margin, which fostered much of the development of imports from other Commonwealth of Nations countries, is subject to periodic negotiations in the General Agreement on Tariffs and Trade (GATT) to which New Zealand is a party. Tariffs are administered by the customs department, which collects about 15% of total taxation by this method.

Import and Exchange Controls.—These controls may be applied to meet serious declines in overseas funds resulting from falling export receipts. If the prices of principal export commodities fall heavily, the country cannot easily provide all the overseas funds normally required to pay for imports. Control of imports by licensing was introduced in 1938 to give priority to essential imports and to keep payments within the funds available. This system continued throughout World War II and the early postwar years. By 1951 most of the licensing control was removed. A similar system, in the form of exchange allocations operated through the banks, was reintroduced following a balance of payments crisis in 1952. Relaxation was almost complete by 1958 when import licensing was again applied and it was substantially tightened in 1961. The application of import and exchange controls is a matter for consultation by New Zealand with the other parties to GATT.

2. Exports.—About 90% of the total value of exports derives from wool, meat and dairy produce. Wool usually constitutes one-third of total exports by value, dairy produce and meat about one-quarter each.

New Zealand wool is principally of crossbred variety, although fine wools are also grown. Dairy produce consists mainly of butter and cheese, but includes dried milk and casein. In the meat trade, New Zealand is famous for high quality lamb and mutton, together with beef, veal and pork. Most of this is exported in frozen form, but better quality beef is merely chilled so that it reaches its destination more like fresh meat.

Other traditional exports are hides, skins and pelts; fish and fish liver oils; apples; peas; grass and clover seeds. Newer exports are forest products, most of which go to the Australian market as timber and paper products, particularly newsprint, kraft paper and pulp.

Wool has always been competed for at auction by a number of countries. The U.K. has been the main traditional market for wool, meat and dairy produce, but other major markets have been developed in Europe, North America, Australia, Asia and the far east. There is an expanding trade in the products of the exotic timber industry, including pulp and paper.

3. National Finance.—Income tax consists of two parts: a flat rate social security income tax of 1*s.* 6*d.* in the pound on all salaries, wages and other income; and a graduated ordinary income tax. All wage and salary earners have tax deducted at the source on the "pay as you earn" system. Other principal sources of revenue are customs duties, beer duty, sales tax, estate and racing duties, interest, profits from trading, and departmental receipts. The largest single revenue item is the income tax. Government revenue amounts to about 35% of national income.

Government Expenditure.—The most costly item of expenditure is represented by the social services. The growth of this program each year has been considerable and represents over 50% of total government expenditure. The item included expenditure on health and public hospitals, education, war pensions and social security. The government contribution toward the social services reflects the extent to which the conception of the welfare state has expanded.

Other expenditures include interest and repayment of debt; works and other capital expenditure; subsidies to stabilize the cost of living in consumer goods; maintenance of public works and services; and expenditure on roads. The remainder represents the cost of general government administration, including defense.

Investment.—The population is increasing at a rate of more than 2% annually and construction work and capital investment must maintain high levels to meet the demand for more production from farms, forests and factories. New Zealand invests more than 20% of its gross national product each year in the provision of capital assets. House and commercial building is at a high level; electrical generating facilities are being doubled in less than ten years; communications are being extended and improved; provision is being made for increasing numbers of students at schools and universities. About 13% of the gross national product goes to private investment and 9% to public investment.

Government capital projects in 1963–64, for example, costing £N.Z.81,000,000 included: electricity; land settlement; house construction; education buildings; railways; telephones and telegraphs; and forest development. The program is financed partly from revenue, reserves and miscellaneous receipts, but principally by borrowing through long-term internal and overseas loans.

Public Debt.—The outstanding public debt in 1962 for the first time exceeded £N.Z.900,000,000. Of this about 84% was held in New Zealand (53% by government departments and 31% by the public), 14% in the U.K. and the remainder in the United States. Except for £N.Z.240,000,000 raised for war purposes, most of the debt was incurred for productive projects and development and is represented by revenue-producing assets such as railways, hydroelectric plant, telephones and housing.

(G. D. L. W.; A. C. Ss.)

4. Banking.—The banking institutions of New Zealand are the Reserve Bank of New Zealand, five trading banks, the Post Office Savings bank and eight trustee savings banks. The Reserve bank, which began operations on Aug. 1, 1934, is state owned. As the central bank, it is authorized to control credit, currency, the transfer of money to and from New Zealand and the disposal of export receipts held overseas. It also has the duty of maintaining a high and stable level of activity in New Zealand insofar as this can be effected fiscally. Between 1939 and 1950 the minister of finance could issue directives to the bank on any aspects of central banking practice or policy. In 1950 the law was amended to require the bank to implement resolutions of parliament in respect of its functions or business. The right of note issue was transferred from the trading banks to the Reserve bank on its establishment. The bank also issues and regulates the supply of coin and since 1936 has managed the public debt.

Two of the trading banks, the Bank of New Zealand and the National Bank of New Zealand, are incorporated by acts of the

New Zealand parliament. All the share capital in the former, which had been partly state owned, was acquired by the government in 1945. It conducts more than 40% of banking business. The other three banks are predominantly Australian institutions. All five banks maintain branches and agencies throughout the country.

Following the assumption by the Reserve bank in 1934 of the sole right to issue notes, the trading-bank notes were withdrawn from circulation. Until 1950 the Reserve bank was required to maintain a minimum reserve of 25% of the aggregate amount of the notes and other demand liabilities. This obligation was abolished in 1950 and the bank was required to hold such reserves as, in the opinion of the board of directors, would provide a reasonable margin for contingencies. "Reserve" is defined as gold coin and bullion, sterling exchange, net gold exchange and net holdings of currencies freely convertible into sterling. From 1933 to 1948 exchange rates were based on a selling rate of £N.Z.125 = £100 sterling but from Aug. 1948 the New Zealand pound was at parity with sterling.

In 1938, to meet a serious fall in overseas reserves, control over foreign exchange was introduced in conjunction with export and import licensing regulations. The exchange control system was extended in 1940 as a war measure and continued with modifications after the war. Under the system, administered by the Reserve bank with the trading banks acting as its agents, foreign currency receipts for export must be paid to a bank; payments for imports are not subject to exchange restrictions (though, as mentioned above, the imports themselves may be subject to licensing); other payments within the sterling area are not restricted except capital exports by New Zealand residents and travel allowances; remittances to countries outside the sterling area are treated on their merits; interest, dividends and profits may be remitted to any country but capital movements are strictly controlled; the export of money is subject to permission but the importation of money is not limited; dealings in nonsterling securities held by residents are subject to Reserve bank approval and the bank is empowered to acquire such securities if necessary.

In pursuance of its function of controlling credit in New Zealand, the Reserve bank introduced in 1942, with the co-operation of the trading banks and as an official measure, a selective control over bank advances aimed at combating speculation and other activities inconsistent with the war effort. This control was continued after the war to avoid expenditure for nonessential purposes or for financing capital expenditure for which other funds were available. The policy was subsequently modified to meet changing conditions and in 1952 was supplemented by increasing the cash balances which the trading banks were required to hold at the Reserve bank. Up to 1952 each bank had to maintain a balance of not less than 7% of its demand liabilities and 3% of its time liabilities. In subsequent years these ratios varied with the trend upward and in the early 1960s stood at about 30% and 10% respectively. The Reserve bank's discount rate is 7%.

In the 1960s the number of open accounts in the Post Office Savings bank reached more than 2,000,000 or about 80% of the population, and the deposits totaled more than £N.Z.350,000,000. Interest at 3% is paid on all deposits. The first of New Zealand's eight trustee savings banks was established at Wellington in 1846. The other seven of these nonprofit savings institutions are at Auckland, Christchurch, Dunedin, Hamilton, Hokitika, Napier and in the Waikato. In the 1960s they had more than 500,000 depositors with savings amounting to more than £N.Z.100,000,000.

In addition, all the savings banks carry national savings accounts which cannot normally be withdrawn for two or three years. They pay 3½% interest and were originally opened in 1940 to help meet war expenditure. In the 1960s these accounts totaled about £N.Z.50,000,000.

5. Coins and Currency.—Gold, silver and bronze coins of Great Britain and Australian gold coins were legal tender in New Zealand until 1935 with Australian silver and bronze in free, though not legal, circulation. New Zealand silver coins were introduced in 1933 and bronze coins in 1939, with denominations and standards of fineness as in the U.K. After 1947 cupronickel coins replaced silver. The Reserve bank issues notes in denominations of 10*s*., £N.Z.1, £N.Z.5, £N.Z.10 and a few £N.Z.50.

(D. L. Ws.; G. D. L. W.; A. C. Sb.)

C. Transport and Communications

The irregular dispersion of population through two broken and mountainous islands has made the provision and operation of modern systems of transport difficult and expensive. Most external trade is by sea. Coastal shipping between a large number of small ports, each serving small and often isolated coastal communities, persisted until the advent of modern roads and motor vehicles in the 1930s.

1. Roads.—Motor vehicles in New Zealand increased from 180,000 in 1930 to 950,000 by 1960, equivalent to one motor vehicle to every 2.5 persons, or one private automobile to every 4.4 persons—higher ratios than in any country outside North America. This growth occurred despite the necessity of importing petroleum products and vehicles and despite high import duties and gasoline tax. Of the 57,000 mi. of formed roads in the country more than 13,000 mi. are part of the national highway system and are the direct financial responsibility of the National Roads board. About 15,000 mi. are tar-sealed or concreted. Dual carriageway highways to motorway or expressway standards have been constructed on the approaches to the main metropolitan centres. With the continued increase in the number of motor vehicles and the high level of taxation on gasoline, the National Roads board, which administers about £N.Z.25,000,000 collected annually in motor taxation, has undertaken increased responsibility for the cost and design of highways and relieved the burdens of the local authorities and ratepayers.

Urban traffic volumes increased so rapidly after 1950 as to cause formidable problems. Express motorways were penetrating the heart of the cities. Multistoried parking buildings were constructed in Auckland. Commercial road services for passengers and freight cover the North and South islands.

2. Railways.—New Zealand railways date from 1863, though the decade 1870–80 saw the most energetic railroad building program. The 3,400 mi. of railways built to a gauge of 3 ft. 6 in. are owned and controlled, with a few minor exceptions, by the state. The route mileage is about equally divided between the two islands. Traffic volumes are much heavier in the North Island, and 40% of freight ton-mileage is carried on the Main Trunk line between Auckland and Wellington. In ton-miles, coal, timber, artificial fertilizers, livestock, cement, petroleum products and agricultural lime are the principal items of freight. The densest traffic, passenger and freight, is carried on the relatively short sections of line between Auckland and Frankton (Hamilton), Wellington–Paekakariki, Wellington–Upper Hutt, and Christchurch–Lyttelton. These last three sections, and the steeply graded 8½-mi. section between Arthur's Pass and Otira in the South Island, are electrified; the remainder of the system is about equally divided between steam and diesel traction.

3. Shipping.—New Zealand is linked by regular shipping services to most parts of the world. By direct routes Great Britain can be reached via the Panama canal in 33 days or via South Africa in 35 days; the voyage can also be made via Australia, the Suez canal and the Mediterranean. Regular Pacific services connect with Vancouver, Can., and San Francisco, Calif., via Honolulu, Hawaii and Suva, Fiji. Trans-Tasman services take 3½ days between Sydney, Austr., and Auckland or Wellington. An overnight ferry service between Wellington and Lyttelton (Christchurch) was in 1962 supplemented by a service carrying railway wagons (freight cars), motor vehicles and passengers between Wellington and Picton. New Zealand's mercantile fleet consists of about 500 vessels. The chief ports are Auckland, Wellington, Lyttelton and Port Chalmers (Dunedin).

4. Air Transport.—The terrain of New Zealand renders surface transport relatively slow and costly. Cook strait imposes further difficulties. Hence internal air transport, especially of passengers and mails, has proved most rewarding. The government-owned National Airways corporation operates a close network of

domestic services on which its aircraft fly more than 8,000,000 mi. annually carrying mail and about 600,000 passengers; figures which in relation to its size and population make New Zealand one of the most air-minded of nations. There are 22 airfields in regular commercial use, half of them with all-weather runways and night-flying facilities.

In addition, aerial work operators use aircraft for spreading fertilizer (about 500,000 tons annually), in distributing seed, poisoned rabbit bait, insecticides and weed killers and in dropping supplies, wire, fence posts and other equipment. Since operations started in 1949, more than 20,000,000 ac. (nearly one acre in every three) have been top-dressed with fertilizer from the air.

Tasman Empire Airways Ltd. (TEAL) and three other airlines provide New Zealand with international services. Besides operating trans-Tasman schedules it provides a feeder service from Auckland to Nandi, Fiji, connecting with trans-Pacific services and with Papeete, Tahiti. Other airlines (Canadian and U.S.) link Auckland with San Francisco, Los Angeles, Calif., and Vancouver. TEAL shares the trans-Tasman route with Qantas and BOAC. By 1959 for the first time the number of passengers entering or leaving New Zealand by air exceeded those arriving and departing by sea. International air services to New Zealand also carry freight and mail.

5. Newspapers and Broadcasting.—Improvements in transport have broken down New Zealand's isolation but New Zealanders are still avid readers of cabled news in the press. The four main metropolitan centres have both morning and evening newspapers with a daily circulation of 750,000. In addition about 35 other dailies are published in smaller towns. Transport difficulties have prevented the establishment of a national daily press but there are three national illustrated weeklies with a total circulation of about 500,000 and numerous weekly or monthly trade and technical papers.

Broadcasting is a government monopoly and was administered as a department of state under a minister of broadcasting until 1962 when a nominally independent broadcasting commission was established. About half of the 34 medium-wave and 2 short-wave radio transmitters broadcast commercial programs. In metropolitan centres there is always a choice of two radio programs and sometimes four. Regular television broadcasting began in Auckland in 1960 and was followed by programs broadcast from transmitters in Christchurch, Wellington and Dunedin. Both radio and television rely largely on "canned" programs from records, tape recordings, videotapes and films.

NEXØ, MARTIN ANDERSEN (1869–1954), Danish novelist who describes working-class life with warmth and unshakable faith in the virtues of the proletariat, was born June 26, 1869, into a working-class family in Copenhagen. As a boy he worked on a farm and as a cobbler's apprentice. He attended high school from 1891 to 1893 and during 1894–96 traveled in southern Europe following an attack of tuberculosis. He taught for several years, but after 1901 he was able to earn his living as a writer. During 1923–30 Nexø lived on Lake Constance and from 1951 to 1954 in eastern Germany. He died at Dresden, June 1, 1954.

Nexø's early works are stamped with the decadence of the 1890s, especially the novel *Dryss* ("Drizzle"; 1902), though his collection of short stories, *Skygger* (1898), contained realistic descriptions of working-class life. A trip to Spain, described in *Soldage* (1903; Eng. trans., *Days in the Sun*, 1929), substituted for his pessimism a belief in the people, the labour movement and the international solidarity of the proletariat—concepts which became dominant in his life. His epic novel, *Pelle Erobreren* (4 vol.,

1906–10; Eng. trans., *Pelle the Conqueror*, 1913–16), describes the progress of a worker—"the unendowed man"—from poverty on the land to an artisan's life in a little provincial town and to trade unionism in the city. Nexø's other great novel, *Ditte Menneskebarn* (5 vol., 1917–21; Eng. trans., 1920–23), is the chronicle of a woman's destiny, fraught with suffering and sacrifice. During this period Nexø also wrote short stories collected in *Muldskud*, i–iii (1922–24).

After the Russian Revolution, Nexø sided with the Soviet Union, which he visited often and praised in his travel book *Mod Dagningen* (1923). His communism antagonized Danish public opinion. His later works include four volumes of reminiscences (1932–39) which are among the most human and best-written memoirs in Danish literature. *Morten hin Röde* (1945) and *Den fortabte Generation* (1948) continue the story of Pelle with a Communist interpretation of political events between the wars.

His motives and ideals, the universal appeal of his subjects and the warmth of his style made Nexø the best-known Danish author after Hans Christian Andersen, and his books have been widely translated.

NEY, MICHEL, Duc d'Elchingen and Prince de la Moskowa (1769–1815), French army officer, one of the emperor Napoleon I's marshals, a military hero whose death sentence made him a martyr against the forces of reaction and political expediency, was born at Saarlouis on Jan. 10, 1769, the son of a cooper. Speaking German (his mother's language) as well as French, he worked for a time as a lawyer's clerk before enlisting in a French hussar regiment in 1788.

Ney rose to high rank in the French Revolutionary Wars before reaching the summit of his greatness in the Napoleonic Wars (*qq.v.*). His former colonel took him as aide-de-camp in 1792. A captain in 1794, he was picked out by J. B. Kléber as a hussar "partisan," and he led light cavalry and infantry in all the actions of the army of Sambre-et-Meuse to 1797, becoming general of brigade in 1796. Under Jean Bernadotte's command, he boldly took Mannheim by surprise in March 1799. He was then promoted general of division to command André Masséna's "vanguard" in Switzerland, but was wounded on May 27, near Winterthur. In August he was transferred by Bernadotte, now minister of war, to Mannheim. In temporary command in chief, he formed the small army of the Rhine in mobile brigades, with which he acted offensively as a typical hussar leader.

A division under J. V. Moreau in 1800 was Ney's first command of infantry of the line in battle; he was conspicuous at Hohenlinden. Napoleon Bonaparte, as first consul, received him cordially in May 1801; and Josephine arranged his marriage to Aglaé Auguié next year. Ney was put in charge of the political and military organization of Switzerland from Oct. 1802 to Dec. 1803; thence he was sent to command the camp at Montreuil.

On May 19, 1804, Ney was made a marshal of the empire. An admirable trainer of troops, he formed the fine VI corps which served under his orders till 1811. In 1805 his brilliant attack across the Danube at Elchingen (for which in 1808 he was created duc d'Elchingen) made the surrender of Ulm inevitable, after which he was sent to clear the Tirol flank. His premature attack at Jena in 1806 and his rash advance almost to Königsberg in Jan. 1807 were criticized by Napoleon, and his action at Eylau was ineffective; but he led the decisive attack at Friedland and was described by the emperor as the "bravest of the brave."

Ney was sent to Spain at his own request in Aug. 1808, hoping for the command in chief, and rallied King Joseph's troops on the Ebro (*see* Peninsular War). He resumed his corps in Napoleon's operations and occupied Galicia and the Asturias temporarily. He resented Masséna's supreme command (1810) and was pained by the losses of his corps; at last, after a most skilful retreat from Portugal, he refused to obey Masséna and was removed by him from his command.

In Aug. 1811 Ney was at Boulogne camp, forming the new III corps for the invasion of Russia. In 1812 he commanded the centre at Borodino and was created prince de la Moskowa (the Moskva river) on the evening of the victory. In the retreat he was a tower of strength, animating the rear guard with his sublime courage. Near Smolensk he was cut off, and his escape across the frozen Dnieper to rejoin Napoleon made him the hero of the army. At Kovno on Dec. 13 he stood in the ranks musket in hand; and he brought the last remnant to Königsberg. The strongest corps of the army of 1813 was given to him; and he commanded two corps in the battle of Bautzen—with less success than was expected. But on Aug. 23 he was called to command three corps detached before Berlin. His defeat at Dennewitz on Sept. 6 showed that he could not command an army, and in 1814 he had only 2,000 of the young guard under Napoleon's direct command. He was the most prominent of the army leaders who confronted Napoleon at Fontainebleau to demand his abdication in April 1814, though the marquis de Caulaincourt, his colleague, thought that Ney exaggerated his account of their interviews and did not want the return of the Bourbons.

Ney's conduct made him a peer and governor of Besançon for Louis XVIII under the first Restoration, but he felt the loss of his grants and was insulted by the attitude of the returned *émigrés* toward his wife at court. Hearing that Napoleon had landed again in France on March 1, 1815, he concentrated the Besançon troops with the famous declaration that the usurper should be brought to Paris in an iron cage; but on March 13, on the impulse of the moment and certainly not by premeditation, he received Napoleon's envoy, and the next day he publicly declared himself for Napoleon. He was received kindly but had no command. The army was already marching when Napoleon called him to the front. He arrived on June 13 without horses or staff and, on June 15, was sent to take charge of the two corps on the left wing. Much controversy has raged over Ney's strategy and tactics in this improvised command at the battle of Quatre Bras (*see* Waterloo Campaign).

At Waterloo, Ney was a battle leader again, not a general. He did not co-ordinate the French attacks; and when he took the initiative of engaging the whole heavy cavalry Napoleon observed that this was premature, as Ney's action at Jena had been. With the cavalry he rode in four charges up to the British squares; and he was dismounted for the fifth time in the last desperate attack of the guards. When all was lost his courage was extinguished; he made no attempt to rally the troops and left the army at once. On June 22 he shocked opinion by a despairing speech in the chamber of peers and on July 6 he left Paris with a passport to Switzerland. He decided, however, to take refuge in the Cantal, where he was arrested on Aug. 5. On hearing this news, Louis XVIII exclaimed "By letting himself be caught he has done us more harm than he did on March 13!"

Neither the king nor his ministers could resist the clamour of the ultraroyalists for blood. The duke of Wellington would not intervene. Though the court-martial declared itself not competent to try a peer, the result of trial by the peers, which began on Nov. 21, was a foregone conclusion (the young duc de Broglie—the future statesman of the July monarchy—alone voted for acquittal); but neither the members of the court-martial nor the peers were forgiven by public opinion. On Dec. 7, 1815, Ney was shot in the Luxembourg gardens, in Paris. He met his death with a soldierly dignity which effaced the memory of his political vagaries and made him, next to Napoleon, the most heroic figure of the time.

NEZ PERCÉ, a tribe of Sahaptin (*q.v.*) lineage on Snake river in Idaho and Oregon. The population was estimated at 6,000 in 1805. There were 1,534 on Lapwai reservation, Idaho, and 83 on Colville reservation, Wash., in 1906; the total Nez Percé population in the 1960s was estimated at 1,500, including about 1,150 reported from the reservation in Idaho. In 1877, under Chief Joseph, they fought the United States, winning some engagements and engaging in a notable but finally unsuccessful re-

treat almost to Canada. They were the largest and easternmost Sahaptin tribe and most affected by influences from the Plains Indians. *See* also CAYUSE; IDAHO: *History*.

NGADJU, Dayak people of southern Borneo (Kalimantan); in older ethnographies they are also called Biadju. In the 1960s they numbered about 80,000 of whom 20,000 were Christians. They inhabit the middle and lower reaches of the Kahajan, Kapuas, Barito and Katingan rivers and also the Sampit region and the upper Serujan. Settlement in the latter areas was made first by those employed as minor government officials; relatives followed, as traders, and thus the Ngadju achieved social and economic, and sometimes numerical, superiority over the original population. Their language has become the *lingua franca* of all southern Borneo, apart from the predominantly Malay coastal region.

Formerly, the villages consisted of one single longhouse, partitioned into a number of rooms for each family. The longhouse was governed by elected elders; a man came to dwell in his wife's house. Present-day villages consist mainly of separate family dwellings. These villages are impermanent, as the Ngadju practise shifting agriculture. Rice is the main crop, yams being a subsidiary, in case of failure of the rice crop. Where rattan is cultivated as a trade crop, permanent settlements arise. Trade consists mainly of bartering forest produce, supplied by inhabitants of the interior, for manufactured goods obtained from Malay or Chinese shopkeepers. The forms of wealth traditionally prized most highly are bronze gongs and large glazed earthenware jars; both objects also have a cosmological significance.

The native religion has an elaborate priestly theology; it recognizes a supreme "total" divinity, which appears in an upperworld and an underworld aspect, with the hornbill and the water serpent as its principal manifestations. In the most important ritual, the *tiwah* (feast of the dead), priestesses convey the souls of the dead to their final abode by long incantations in the spirit language. Long cycles of sacred tales are also important in the rich oral literature. *See* also BORNEO: *The People: The Dayak Peoples*; DAYAK.

(P. E. DE J. DE J.)

NGAMI, LAKE, a shallow depression at the southeastern (southwest) corner of the 4,000-sq.mi. inland delta of the Okovango (*q.v.*) river in Ngamiland in the northwest of Bechuanaland protectorate, southern Africa. It lies 43 mi. by road from Maun, the chief town of Ngamiland, and 320 mi. from the railway through the eastern part of the protectorate. The lake was discovered by David Livingstone in 1849. Lying 3,000 ft. above sea level, it is 40 mi. long and 6–10 mi. wide.

Ngamiland is part of the great sandy Kalahari desert (*q.v.*). Around Lake Ngami the country is well timbered with scrub and long thorn trees and supports a large cattle population. The local village is Sehitwa, midway along the northern margin of the lake.

The flow of water within the swamps of the inland delta is complex, and outflow normally follows annual floods which begin in March at the head of the delta and reach the base, near Maun, about four or five months later. The Taokhe, the largest southflowing channel of the delta, is said to have been the main source of supply to the lake, but, because of blockages caused by extensive papyrus growth in the channels among the swamps, water has not reached the lake from the Taokhe since 1887. The lake is fed with floodwater from the combined Kunyere and Nghabe rivers which drain toward Lake Ngami and follow a northeast-southwest course along lines of parallel faults that form the base of the delta. These channels join at Toteng at the northeastern end of the lake. Inflow varies greatly from year to year, and is generally insufficient to maintain perennial water in the lake.

Lake Ngami has no natural outlet. If it became filled, the Kunyere and Nghabe valleys would be submerged, and any excess water would be deflected into the Botletle river, 12 mi. south of Maun.

(W. G. BD.)

NGONI (ANGONI). About 500,000 people (as of the 1960s), belonging to about a dozen groups scattered throughout eastern Africa, call themselves Ngoni. They, like the Zulus, belong to the Nguni branch of the Bantu people. Each group of Ngoni has a history of migration from the vicinity of Zululand (*q.v.*), south Africa, in about 1820–35, and their common name is derived from a praise title current in the Zululand area. The growth of the Zulu empire under Chief Shaka (Chaka) caused many refugee parties and bands led by his rivals to move outward from Zululand in search of more favourable conditions. Some, like the Fingo who entered Cape Colony (Cape of Good Hope), and the Tlokwa under Chief Mantatise, remained in the south; others, like many Ngoni, went north. Chief Zwangendaba led his Ngoni party to Lake Tanganyika, where it split into three, and the descendants of his group (the Ngoni cluster proper; pop. 350,000) are located in northern Nyasaland, in Northern Rhodesia, and in Songea and Kahama districts of Tanganyika. Chief Soshangana's Ngoni went to Gazaland, Portuguese East Africa. Mzilikazi, one of Shaka's generals, took his party of Ndebele (*q.v.*) to Southern Rhodesia, and it is probably from him that the Maseko Ngoni, now in southern Nyasaland, broke away.

Each Ngoni group formed a small independent state with a central administration based on hereditary patrilineal succession. It raided its weaker neighbours for some of its food supply, and when the fertility of its own cultivated area was exhausted, the group as a whole moved elsewhere, seeking fresh fields and pastures at the expense of new enemies.

The superior Ngoni military organization, based like that of the Zulu on universal conscription into age-set regiments, enabled them to capture many of the people whose lands they seized or pillaged. Some captives, particularly in Tanganyika, were sold to Arabs as slaves, but many were assimilated into the tribe, some achieving high rank in the army and administration. Despite losses through continual warfare, the population increased greatly, leading eventually to splits in the state and dispersal of rival segments.

Internally each state, at least among Zwangendaba's people, was divided into numerous segments, many of which were under the nominal leadership of queens. Smaller segments controlled by lords were likewise each subdivided among the several wives of the lord. Selected captives were appointed lieutenants of their lord, were placed in command of his dependents and might succeed him if he had no son. The large compact villages, with their central cattle barns, were built fairly close to one another, each village containing about 2,000 or 3,000 inhabitants. A belt of empty no man's land surrounded the settled area, isolating it from the territories of the tribes raided by the Ngoni.

At the end of the 19th century Portuguese, British and German forces invaded the hinterland where the Ngoni had been virtually unchallenged for 50 years. By 1910 all Ngoni groups had come under white control. The high density of population consonant with their former life of migratory brigandage has, under settled conditions, caused serious shortage of land, accentuated in some instances by alienation of land to whites. *See* also NGUNI.

(J. A. Bs.; X.)

NGUNI, the largest cultural and linguistic division of the Bantu of southern Africa numbering 6,500,000 in the 1960s. They are cattle-herding, subsistence farmers who live in patrilineal homesteads or kraals (*umuzi*) which combine into localized exogamous clans. Nguni traditions say that they came from farther north and divided into four main stocks: Xhosa (*q.v.*), Ntungwa, Lala and Mbo. By 1900 tribes derived from these stocks were distributed in the three cultural and territorial areas of: (1) the southern Nguni, known to Europeans as Kaffirs; *e.g.*, the Xhosa, Tembu and Mpondo of the Transkei region of Cape of Good Hope

(pop. 2,380,000); (2) the Transvaal Nguni, called by their Sotho neighbours Ndebele (pop. 144,000); (3) the Natal Nguni (pop. 2,048,000). Warfare among the latter resulted in the ascendancy of the Zulu nation and produced migrations from Natal of Nguni under various military leaders (*see* ZULULAND). Those who moved north combined with the various non-Nguni people they conquered to become: (4) the Swazi (*q.v.*) nation formed by Sobhuza and his successor Mswazi (pop. 410,000); (5) the Ndebele (*q.v.*) nation of Southern Rhodesia (pop. 300,000); (6) the Shangana nation of Gazaland, Portuguese East Africa (Mozambique), formed by Chief Soshangana (pop. 400,000 in South Africa, figures not available for Portuguese East Africa); (7) the Ngoni (*q.v.*) cluster of chiefdoms which derive from Chief Zwangendaba and which are distributed in Nyasaland, Northern Rhodesia and Tanganyika territory (pop. 350,000). Less successful Ngoni migrants to the west became dispersed in the southern Nguni area as the Fingo (Mfengu), Bhaca, Xesibe and other tribes.

NIAGARA, FORT, a historic fortification in Niagara county, N.Y., U.S., on the east bank of the Niagara river where that river flows into Lake Ontario. As the strategic key to the Great Lakes it was a major military objective in the Anglo-French contest for the interior of the North American continent in the 18th century. As early as 1678–79, La Salle established a trading post there, and in 1687 the French erected Ft. Denonville, only to abandon it the following year. Ft. Niagara was built by the French in 1725–27 and rebuilt in 1756, as tension mounted over control of the Ohio valley. A British force captured the fort on July 24, 1759, in one of the most decisive battles of the French and Indian War (*q.v.*). Gen. John Prideaux, the British commander, was killed on the field and Sir William Johnson took his place. The British enlarged the fort after the war and during the American Revolution used it as a base for raids into the Mohawk valley. Along with other British posts on soil nominally American by the peace of 1783, it was not evacuated until 1796. During the War of 1812 the British under John Murray captured the fort in 1813. From its return to the United States on March 27, 1815, until Dec. 31, 1945, it was garrisoned by the regular army, except for the years 1826–36. Later the vicinity was designated Fort Niagara State park.

NIAGARA FALLS, a city and port of entry of Welland county, Ontario, Can., on the left bank of the Niagara river opposite the falls, 43 mi. S.E. of Hamilton. It is connected with the U.S. town of Niagara Falls on the opposite bank by the renowned Rainbow and Whirlpool Rapids bridges. First named Elgin in 1853, then Clifton in 1856, the town became known as Niagara Falls in 1881. The first suspension bridge across the gorge at Niagara Falls was completed in 1855 by John Augustus Roebling (*q.v.*). In 1904 Niagara Falls was incorporated. Pop. (1961) 22,351. Its importance is largely due to the cataract, a tourist attraction and major source of electrical power for Ontario. Manufactures include chemicals, fertilizers, abrasives and refractories, silverware, cereals, machinery and sporting goods. Queen Victoria park, of the provincial Niagara Parks commission, extends along the bank of the river and includes the unique Oakes Garden theatre and carillon tower. (F. G. R.)

NIAGARA FALLS, a city and port of entry of Niagara county in western New York, U.S., is located about 20 mi. N.N.W. of Buffalo at the great falls of the Niagara river, opposite Niagara Falls, Ont.

Each year the city accommodates more than 2,000,000 visitors to the falls, which have proved to be one of the most durable and popular tourist attractions in the world. At night the falls are illuminated by multicoloured floodlights from Victoria park on the Canadian side. Behind the façade of a busy tourist mecca, however, is a thriving industrial community which converts the power of the great river into useful products enjoying both local and national importance. Electrochemical and electrometallurgical industries predominate, with chromium silicon, silicon carbide, carbon and graphite, caustic soda, chlorine, fluorine and hydrazine accounting for a major part of their output. Paper products, rocket components, storage batteries, foods and business forms are also produced. Most of the industries are located in an L-shaped section which lies along the upper Niagara river east of the city and then northward along its eastern margin.

The falls, which Jacques Cartier (*q.v.*) heard about but did not visit on his voyage of 1535, were first described by Father Louis Hennepin (*q.v.*), a Franciscan missionary who saw them in 1678. As the only break in the all-water route between the St. Lawrence river and the upper Great Lakes, the area around the falls had great strategic value in colonial times. A French fort was built in 1745 and another (Little Niagara) in 1751 to supplement Ft. Niagara (*see* NIAGARA, FORT) at the mouth of the river. In 1759 both forts were burned by Chabert Joncaire, French master of the portage, to prevent their falling into British hands. Under Joseph Schlosser, a German captain in the British army, Ft. Schlosser, part of which has been restored, was erected in 1761. Augustus Porter who purchased the area around the falls and established a gristmill in 1805, saw in the mighty cataract power that would some day build a thriving city, and so he named his settlement Manchester after the great English industrial centre. Manchester, with Ft. Schlosser, was burned by the British on Dec. 19, 1813 during the fighting on the Niagara frontier in the War of 1812, and thereafter remained a small rural community which seemed to be caught in the backwash of its larger neighbour, Buffalo. The opening of the Erie canal in 1825 seemingly doomed the region to the life of a rural tourist centre, for traffic which had once moved over the portage from Lewiston below the falls to Ft. Schlosser dwindled and disappeared, apparently taking with it any hope of an industrial future. In 1847, Porter tried to interest speculators in an attempt to build a canal for hydraulic power from the river above the falls to a point roughly one mile downriver from the brink. He failed and others went bankrupt digging that canal, completed in 18[illegible] through the tough Onondaga limestone that underlies the region. Jacob Schoelkopf bought the "ditch" in 1877 and began to sell the water to mills along the bank downstream from the falls. In 18[illegible] he installed a small generator at the base of the cliff and the true future of Niagara Falls, hydroelectric power, was found. Another great step was taken when Edward Dean Adams (1846–1931) formed the Niagara Falls Power company in 1886 to develop the potential of the falls. During World War I the Schoelkopf holdings were merged with Adams' company and the modern era of industrial growth really began. To protect their aesthetic value, the amount of water which may be diverted from either the U.S. or Canadian (Horseshoe) falls is limited by international treaty. In addition, Goat Island, which separates the U.S. and Canadian falls, several smaller islands and Prospect park, 10 ac. on the brink of the gorge, were set aside as a state park in 1885.

In 1892 Manchester, by that time renamed Niagara Falls, and the downstream village of Suspension Bridge, formerly Niagara City, were merged and incorporated as the city of Niagara Falls which in 1916 adopted a council-manager form of government. Niagara university (Roman Catholic, 1856) is located in the suburbs.

A wagon and foot bridge was constructed across the gorge in 1848 and the first railway bridge, a suspension type by John Augustus Roebling (*q.v.*), was completed in 1855. The falls have been the scene of many daring exploits since Sam Patch leaped 100 ft. into the gorge from a specially built platform in 1829. Several persons have safely plunged over the Canadian falls or ridden through the whirlpool (about 1½ mi. below the falls) in barrels. In 1859 and again in 1860 (on the occasion of the visit of Edward VII, then Prince of Wales) Charles Blondin, a French acrobat, performed on a tightrope stretched across the gorge. Probably the most amazing occurrence at the falls, however, happened in 1960 when seven-year-old Rodger Woodward was accidentally swept over the falls and survived with little injury.

Horseshoe Fall, adjoining the left (Canadian) bank, and the American Fall (centre right), alongside the right bank. The river, spanned by Rainbow Bridge (centre), flows north through the gorge toward Lake Ontario

NIAGARA RIVER AND FALLS, flowing in a northerly direction from Lake Erie to Lake Ontario, a distance of about 28 mi., constitute part of the boundary between the United States and Canada, separating the state of New York from the province of Ontario. It is the drainage outlet of the four upper Great Lakes, whose aggregate basin area is about 260,000 sq.mi. The mean discharge of the river at its head is about 196,200 cu.ft. per second, with a range from a low monthly mean in winter of about 119,000 cu.ft. to a high monthly mean in summer of about 245,000 cu.ft. per second.

For a distance of about 5 mi. from its head the river flows through a single channel; then it is divided into two channels by Strawberry and Grand islands, the eastern or U.S. channel being about 15 mi. long and the western or Canadian channel being about 12 mi. long. At the foot of Grand Island these two channels merge into one about 3 mi. long, extending to Niagara falls (*see* below). Downstream from the falls the gorge section of the river is 7 mi. long; the river then flows across a lake plain for a distance of 7 mi., to Lake Ontario.

The river is navigable from its source in Lake Erie to the upper rapids, a distance of 20 mi. in which the river descends about 10 ft. From the head of the rapids to the brink of the falls the river descends 50 ft.; then it drops 167 ft. in the falls and descends 98 ft. farther in the lower rapids of the Niagara gorge. In the last 7 mi. the river descends less than a foot, and this section (from Lewiston, N.Y., to the mouth) is navigable. The total descent of the river, from Lake Erie to Lake Ontario, is 326 ft.

Niagara Falls.—The falls of Niagara are justly celebrated for their grandeur and beauty, and are viewed every year by over 2,000,000 visitors. The falls are in two principal parts, separated by Goat Island. The greater division, adjoining the left (Canadian) bank, is called the Horseshoe fall; its height is 158 ft., and the length of its curving crest line is about 2,600 ft. The American fall, adjoining the right bank, is 167 ft. high and 1,000 ft. broad.

The water is free from sediment, and its clearness contributes to the beauty of the cataract. In recognition of the importance of the waterfall as a great natural spectacle, the province of Ontario and the state of New York retained or acquired title to the adjacent lands and converted them into public parks.

Excellent views of the falls are obtained from Queen Victoria park on the Canadian side; from Prospect point on the U.S. side at the edge of American fall; and from Rainbow bridge, which spans the gorge about 1,000 ft. downstream from Prospect point. Visitors may cross from the U.S. shore to Goat Island by footbridge, and may take an elevator to the foot of the falls and visit the Cave of the Winds behind the curtain of falling water. The Horseshoe fall has been receding, or migrating upstream, at the average rate of nearly five feet per year in historic time.

Geologic History.—The shaping of the gorge and the maintenance of the falls as a cataract depend upon peculiar geologic conditions. The rock strata in the Niagara gorge are nearly horizontal, dipping southward only about 20 ft. to the mile. The uppermost layer of hard Niagaran dolomite is underlain by soft layers which are easily worn away, and this provides the conditions for keeping the water constantly falling vertically from an overhanging ledge during a long period of recession.

The river came into existence late in the Glacial or Pleistocene epoch (*q.v.*) when the margin of a great continental ice sheet melted back and exposed the escarpment of Niagaran dolomite rock, allowing the discharge from the Lake Erie basin to pour over it. Recession of the falls created the Niagara gorge, which extends about 7 mi. upstream from Lewiston to the present falls. The age of the gorge, when calculated by dividing its length by the average rate of recession of the falls in recent time, is about 7,000 years. Other considerations led some geologists to estimate an age as great as 25,000 years. Determinations of the age of the last glacial ice advance in the area suggest, however, that the Niagara river is about 10,000 years old. Continued recession of the falls toward Lake Erie will ultimately cause the drainage of that lake but such an event is not expected to occur within the next 25,000 years.

The Niagara gorge runs 2½ mi. N.N.E. from the Horseshoe fall to the railway bridges, and this stretch is known as the Maid-of-the-Mist pool. It has a descent of only five feet, and is navigable by excursion boats. Downstream, the river flows one mile northwest through the narrow, Whirlpool Rapids section to the Whirlpool; this section differs from the rest of the gorge because there the river intersects an old channel which was formed before the last glacial ice advance and was later filled with glacial drift. At the Whirlpool the gorge makes a 90° bend to the northeast and extends two miles, then runs one-and-one-half miles north to the foot of the Niagara escarpment at Lewiston, N.Y.

Navigation.—Water-borne traffic from Lake Erie passes through the upper single channel and the U.S. channel to Tonawanda, N.Y., to enter the New York State Barge canal. That canal, with a 12-ft. minimum depth, connects with the Hudson river and has branches which connect with Lake Champlain and with Lake Ontario.

The principal shipping between Lakes Erie and Ontario, however, passes through the Welland Ship canal which lies a few miles west of the Niagara river. It extends from Port Colborne, Ont., on Lake Erie, about 27 mi. north to Port Weller, Ont., on Lake Ontario. The minimum depth in the canal is 27 ft., and the ships which pass through it include vessels engaged in trade between the upper Great Lakes and Europe. (*See* WELLAND SHIP CANAL; SAINT LAWRENCE SEAWAY.)

Hydroelectric Power.—Canada and the U.S. agreed, in a treaty signed in 1950, to reserve sufficient amounts of water for flow over Niagara falls to preserve their scenic value. The agreement provided for a minimum daytime flow during the tourist season of 100,000 cu.ft. per second, and a minimum flow of 50,000 cu.ft. per second at all other times. All water in excess of these amounts, estimated to average about 130,000 cu.ft. per second, was made available for diversion for power generation, to be divided equally between the U.S. and Canada. The total hydroelectric capacity of the river was fixed at about 3,600,000 kw. This was developed by power plant installations, completed or under construction by 1960. The power plants receive water diverted from the river above the falls and carried to them by open channels or tunnels, and they discharge the water into the gorge at various places below the falls. Much of the energy was used in nearby electrochemical industries for the manufacture of aluminum, ferrosilicon, carborundum, artificial graphite, liquid chlorine, calcium carbide, cyanamide and other products. The remainder was transmitted to various cities for miscellaneous uses. The maximum distance to which this power was transmitted was somewhat in excess of 200 mi.

The principal cities located along the river are Buffalo, N.Y., at the eastern end of Lake Erie; Tonawanda, N.Y., the western terminus of the New York State Barge canal; Niagara Falls, N.Y., and Niagara Falls, Ont., situated beside the falls and gorge; Lewiston, N.Y., at the mouth of the gorge; and Niagara-on-the-Lake, Ont., at the mouth of the river.

Fort Niagara, a 288-ac. U.S. military reservation on the east bank at the mouth of the river, is on the site of a blockhouse built by the French in 1678–79. It includes Old Fort Niagara, which was built by the French in 1725–27 and is still standing. (J. L. Hr.)

NIAMEY, the capital of the Republic of the Niger, west Africa, is situated on hills above the left bank of the Niger river, in the southwest corner of the republic. Pop. (1959) 30,030. Before it became a capital in 1926 it was merely a collection of villages inhabited by Djerma (Zarma) cultivators; latecomers were Yoruba from Nigeria, Hausa, and people from the republics of Dahomey and Togo, including traders, weavers, smiths, leatherworkers and cloth merchants. There are few industries (oil works, brick factories, repair shops), but Niamey is commercially important because of its position at the intersection of east–west–south

land routes and the Niger. It also has an important airport.
(J. D.)

NIAS, largest of the chain of islands west of Sumatra, Indonesia, lying immediately north of the Mentawai (*q.v.*) group. Administratively it is a *kabupaten* (regency) of the province of Sumatera-Utara (North Sumatra). The island is 80 mi. long and nearly 30 mi. wide, with an area of 1,569 sq.mi. The topography is hilly, with rocky or sandy coasts, often dangerous for landings. Geological structure is much like that of western Sumatra, but there are no volcanoes; earthquakes do occur. Highest elevation is 2,300 ft. The island is densely populated, especially in the valleys of the south and around the chief town and port, Gunungsitoli on the east coast. Population in 1961 was 314,829.

The indigenous population belongs to the early (Proto-) Malay stock and speaks dialects of a distinct branch of the Malayo-Polynesian language family. Most of the people are animists, but some, especially in the north, are converts to Islam and Christianity. Marriage is exogamic and wives are bought. At death, a man's wife and property pass to his brother. Land belongs to the settler and is inherited in the direct line. A council of notables assists hereditary chiefs in administration. The Dutch, who began trading there in 1669, suppressed slave trade.

In North Nias villages are small, situated on hilltops, each enclosing a stone-paved rectangle. In South Nias the villages are larger and include a bathing pool. Those on high sites have broad paved stairways with remarkable sculptures. Megalithic monuments and wooden sculptures, common all over the island, are more elaborate in the south; they honour the dead or represent fertility symbols. The houses, built on piles, contain several families, the private quarters adjoining the large communal room. The chief's house is very large with high roof and massive pillars and beams, often skilfully carved. The main crops are yams, sweet potatoes, rice and maize, grown on temporary fields. Pigs and chickens provide most of the meat. Copra is the export commodity. The Niasese are good craftsmen in gold and silver. A road, mainly a trail, runs around the island and connects with another road through the centre. There is no good port, and ships calling at Gunungsitoli must anchor offshore. (J. O. M. B.)

NIBELUNGENLIED, the generally accepted name of a German epic poem written about A.D. 1200, although *Der Nibelunge Nôt* would appear to have been an earlier title. Neither is entirely satisfactory as an indication of the content of the poem; that this was felt at an early date is shown by the superscription of one of the manuscripts, from the early 14th century: "the book of Kriemhild."

The story as we have it has a long history behind it, and as a result contains a number of disparate elements which have not always been completely reconciled; the following summary of the contents, while aiming at presenting the story as a consecutive and coherent whole, does not seek to suppress inconsistencies where they are prominent. The word *Nibelung* itself presents difficulties. In the first part of the poem it appears as the name of Siegfried's lands and people and his treasure, but throughout the second it is used as an alternate name for the Burgundians. A possible explanation is that the Nibelung treasure is, after Siegfried's death, acquired by the Burgundians.

The Story of the Poem: Siegfried and Kriemhild.—The poem begins with two cantos (*Aventiuren*) which introduce respectively Kriemhild, a Burgundian princess of Worms, and Siegfried (*q.v.*), a prince from the Lower Rhine. The action begins in Canto 3, which describes Siegfried's determination to woo Kriemhild, in spite of his parents' warning of the dangerous nature of the suit; his departure; and his arrival at Worms. There Hagen, the henchman of King Gunther (Kriemhild's brother), identifies Siegfried, even though he has never seen him, and gives a brief account of his former deeds—the killing of a dragon, from which resulted Siegfried's horny skin, and the acquisition from two quarreling brothers of their treasure. Siegfried does not mention his suit, but challenges Gunther to fight to defend his lands; a reconciliation is achieved (but not before some hard words pass, with Siegfried twice addressing Hagen in challenging tones), and Siegfried stays at the court. Messengers arrive from the Danes and Saxons, declaring war, but Siegfried offers to lead the Burgundians and distinguishes himself in the battle. Kriemhild is delighted, and during the festivities on the warriors' return the two meet for the first time. Their mutual affection has the opportunity to develop during Siegfried's subsequent residence at the court, where he occupies a privileged position.

At this point an entirely new element is introduced, which is to dominate the action for a long time: the story of the wooing of Brunhild (*q.v.*). News from overseas reaches the court of Worms which tells of a queen of outstanding strength and beauty who may only be won by a man capable of matching her in athletic prowess. Gunther expresses his intention of wooing her but he is warned by Siegfried of the danger to which he would expose himself. Hagen suggests that Gunther allow Siegfried to help him; Gunther accepts the suggestion and Siegfried agrees, on condition that Gunther promise him the hand of his sister Kriemhild if he succeeds. Throughout the expedition Siegfried takes charge, even more decisively than he did in the Danish-Saxon war, and gives instructions on the conduct of the expedition down to the smallest details; his ability to pilot the expedition to Brunhild's abode on Isenstein is a variant of the well-known motif in medieval German literature of the much-traveled warrior who is able to give advice and help to the master with whom he has taken service. It is in the same tradition when one of Brunhild's followers singles out among the newcomers one who "looks like Siegfried." This is no surprise to Brunhild because of the very nature of her vow, which was to marry only the best and bravest. Siegfried, however, presents himself not as the wooer, but as Gunther's vassal; and in the ensuing contests Gunther goes through the motions of deeds in fact performed by Siegfried in his cloak of invisibility. When Brunhild is defeated she accepts Gunther as her husband. After an interlude in which Siegfried goes to his own "Nibelung" lands—where his treasure lies—to fetch some followers, he is sent on ahead to Worms to announce Gunther's victory and his impending arrival with his bride. Siegfried and Kriemhild also are married, as promised, but Brunhild remains ill at ease, ostensibly because she is hurt at seeing her sister-in-law married to one who is, as she has been told, a vassal of Gunther's. After a period during which Siegfried returns with Kriemhild to his own domains, they are invited, at Brunhild's request, to Worms. During this visit the two queens quarrel over precedence. In the course of the quarrel Kriemhild reveals to Brunhild the treachery which had been practised on her when Siegfried entered the bridal chamber invisibly to overcome her resistance to Gunther.

It is at this point that the figure of Hagen becomes prominent. He seizes the opportunity of coming to the defense of the injured Brunhild and takes the initiative in plotting vengeance. The plan is to entice Siegfried away from the court so that he can be killed, but it is first necessary to ascertain where and how he is vulnerable. Hagen succeeds in ingratiating himself into Kriemhild's confidence, and learns the secret of Siegfried's one vulnerable spot; he also strikes the fatal blow.

It is noteworthy that during and after these events Brunhild slips almost unnoticed out of the story, and the death of Siegfried is seen not so much as vengeance by her, but rather as a blow struck by Hagen, who was becoming suspicious of Siegfried's growing power; all emphasis is on Kriemhild's grief and her hatred of Hagen. Siegfried's funeral is conducted with great ceremony. Kriemhild decides to remain at Worms with her mother and younger brothers, but for long remains estranged from Gunther and Hagen. Hagen persuades Gunther to attempt a reconciliation, so that they may have the benefit of Siegfried's treasure, and Kriemhild agrees to make peace with Gunther. The treasure is then brought to Worms but Hagen, seeing that Kriemhild is distributing it, and fearing the influence she may gain, seizes it and sinks it in the Rhine.

The Fall of the Burgundians.—The preceding events close what is generally known as the first half of the poem; the second is simpler in structure. Etzel, king of the Huns, who is widowed, sends messengers to Worms to ask the hand of Kriemhild. Gunther is willing, in spite of Hagen's warnings, and Kriemhild agrees

when she sees the possibilities for vengeance this match could offer her. After many years she persuades Etzel to invite her brothers to his court, and is particularly insistent that Hagen shall come. Hagen suspects Kriemhild's motives and warns his masters against accepting, but he only succeeds in persuading them to go armed; and it is not until they have crossed the Danube that they are convinced. On their arrival Kriemhild's plan is quickly revealed and. although there is much large-scale fighting, the poet makes clear the essentially personal nature of the conflict; the climax is reached when Hagen—as the last survivor of the Burgundians and, though bound, still defiant—faces Kriemhild, who kills him when he still refuses to reveal where Siegfried's treasure is hidden. She in turn is executed by Hildebrand, who is at Etzel's court with his master Dietrich von Bern (*q.v.*). "Daz ist der Nibelunge nôt" ("that is the story of the destruction of the Nibelungs [or Burgundians]") are the final words; and they are an apt description of the second half of the poem.

The Elements in the Story.—In this story some elements of great antiquity are discernible. In the first part one recognizes the story of Brunhild, which retains its separate existence in Old Norse literature; there are also the brief allusions in Canto 3 to the two ancient stories of the heroic deeds of Siegfried; and finally the whole of the second part is the story, albeit with a different motivation, of the Fall of the Burgundians which exists in an older form in the *Eddaic* poem *Atlakvida* ("Lay of Atli"). It was the great merit of the scholar Andreas Heusler to isolate the stories of Brunhild and the Fall of the Burgundians as the two mainstays of the action. It is, however, no mere formal joining together of two separate stories, which is what they originally were; the poet sought by various devices to combine the different elements into a meaningful whole in which the component elements would be integrated. One of the major alterations is in making Kriemhild, and not Etzel, as was originally the case, send the treacherous invitation; but this must have been done much earlier, for Saxo Grammaticus refers to the recital, in 1131, of the poem of the "well-known treachery of Kriemhild against her brothers." Once this step had been taken it would not be difficult to envisage a combination of the Burgundian and the Brunhild stories into one; for, although the emphasis in the latter was on Brunhild, Kriemhild suffers a blow through the death of her husband which she may well be expected to wish to avenge. Other inconsistencies and contradictions, which could not be revealed in the summary above, emphasize the long history of the subject matter. Karl Lachmann's view that it is a collection of 20 originally separate short poems was held, and debated, for many years; it was, however, superseded after the appearance of Heusler's principal work, in which he demonstrated the central position of two themes, and explained the difference in length between the old short lays and the long epic in terms of a different style of narration.

Heusler's views on the role of these two stories in the history and structure of the poem found such general acceptance that the importance of the other elements, with which he also dealt, tended to be overlooked. After about 1940, however, attention was concentrated on them, perhaps excessively. An example of these elements is the scene in which Siegfried meets his death. In the Norse versions, particularly in the older ones, the death of Siegfried is dismissed in a few words as a fact which has to be recorded, and this is perfectly consonant with the theme of the original story, in which Brunhild was the principal character and Siegfried the means by which her problem arose. The role Siegfried plays in the corresponding part of the *Nibelungenlied* is still comparable. Much is made, it is true, of his conduct of the expedition and of the part he plays in the actual contests, but from the time of Brunhild's arrival at Worms he becomes a passive participant, until the plot for his death is hatched. From this moment all attention is concentrated on him and Kriemhild. After Hagen has elicited his vital secret from Kriemhild there follows a carefully constructed scene in which she confesses her premonitions and tries to dissuade Siegfried from participating in the hunt which has been arranged: she claims to have had dreams which point to her husband's sudden death. He, however, with unquestioning confidence in his own powers and—note the dramatic irony—equally confident of the friendship of all, brushes aside her objections and goes out, utterly happy, to what is to be his last hunt. This picture of a young hero, in the fullness of his powers and at the height of his happiness, is further developed in the hunt itself, culminating in a boisterous practical joke which he plays on his fellows. In the final act, the race to the spring, he again demonstrates his physical superiority and, in his refusal to drink until Gunther has drunk, his meticulous regard for courtly precedence. By this very delay he gives Hagen the opportunity to strike the fatal blow while he is bending over the water. There is no source in Germanic antiquity for the details which make this scene so effective, and the poet would appear to have had his inspiration from a contemporary Romance epic *Daurel e Beton*.

Similarly there is a scene in the second half which also serves to heighten the tragedy by relieving the tension. The purpose of the journey of Gunther and his followers is known to the audience from the beginning; and although the participants, apart from Hagen, at first suspect nothing, the tension rises as they proceed. It is, however, relieved by a few days' rest at Bechelaren, where the party is entertained by the margrave Rudeger and his wife and daughter. The idyllic nature of the interlude is stressed by the betrothal of the youngest of the Burgundian princes Giselher and the margrave's daughter; it is agreed that the marriage shall take place on their return. The effectiveness of the scene has long been universally recognized, and in 1945 Friedrich Panzer suggested a source, not a literary one, but an event in 12th-century history. In 1189, when passing through Hungary on his crusade, the emperor Frederick I was festively entertained by King Bela of that country and his wife, and the marriage of Frederick's second son with King Bela's daughter was arranged; the marriage was to take place on the return of the emperor and his son from the crusade in which, in fact, both met death. Panzer has drawn attention to possible contemporary literary and topical historical sources for other incidents.

Both approaches have proved fruitful in determining the author's theme, or whether in fact he had a single theme, and in estimating his poetic achievement. It cannot be disputed that the second part of the poem deals with the disaster that overcame the Burgundians, or Nibelungs (and to that extent the title *Der Nibelunge Nôt* is apt), nor that this disaster was the deliberate purpose of Kriemhild. It is preceded by a story in which Siegfried plays a prominent part, and to the extent that Siegfried is Kriemhild's husband and attention is concentrated on his death, the events of this first part may be considered integrally connected with those of the second. There are other indications that it was the poet's intention to present the story in this way: Kriemhild is the first person to be introduced and the poem ends when she is killed. She is introduced, too, in a way which leads one to believe that she is to play an important role. The poet's treatment of Brunhild is consonant with such a purpose; her story once existed in its own right and ended when her honour was satisfied, but in the *Nibelungenlied* the death of Siegfried is presented in the very different light discussed above. Further, there is the attention paid to Hagen. Early in the story his words to and about Siegfried indicate anger and resentment; he takes the initiative in the plot against him and strikes the blow, earning Kriemhild's uncomprising hatred by having tricked her into revealing his one vulnerable spot. Particularly striking is the scene in the second part where, on their arrival at the court of the Huns, Hagen remains defiantly seated before Kriemhild, with Siegfried's sword ostentatiously laid across his knees. To what extent this concentration on Kriemhild and on the enmity between her and Hagen was already present in the sources must remain a matter of conjecture, but the consistency with which it is carried through would seem to suggest that it was the poet's intention to stress the theme.

Dating and Manuscripts.—The poem was written in the classical period of medieval German literature, but it holds a special position in it. A characteristic feature of the literature of that period is the emphasis on the current "courtly" virtues of

moderation and refinement of taste and behaviour. The *Nibelungenlied*, with the violence of its emotions and its uncompromising emphasis on vengeance, bears unmistakably the mark of a different origin: the heroic literature of the Teutonic peoples at the time of the migrations. The basic subject matter also goes back to that period, for there can be no doubt that the story of the destruction of the Burgundians was originally inspired by the overthrow of the Burgundian kingdom at Worms by the Huns in A.D. 437, and the story of Brunhild and Siegfried may have been inspired by events in the history of the Merovingian house of the Franks about A.D. 600. Much of the heroic quality of the original stories has remained in the poem, particularly in the poet's conception of Hagen in the second half. Nevertheless, to judge by the manuscript transmission, which can be traced through three whole centuries, the poem became and remained popular in spite of its "out-of-period" characteristics. The most important of these manuscripts are the Hohenems-Munich (*A*), the St. Gallen (*B*) and the Hohenems-Lassberg (*C*). Lachmann regarded *A* as the best and based his edition on it; Holtzmann and Zarncke later made the same claim for *C* and used that; but the consensus now favours *B*, on which the standard edition of Karl Bartsch is based. *C* is the earliest and was written in the early 13th century. Some of the later manuscripts make quite substantial alterations to the subject matter, but even *A*, *B* and *C* show differences which go beyond mere verbal variation, including a difference of over 100 in the number of strophes.

See also references under "Nibelungenlied" in the Index.

BIBLIOGRAPHY.—The literature on the poem is enormous, and forms the subject of special bibliographies: *see* T. Abeling, *Das Nibelungenlied und seine Literatur* (1907; with a supplement, 1909); and M. Thorp, *The Study of the Nibelungenlied* (1940). The standard edition is *Der Nibelunge Nôt, mit den Abweichungen von der Nibelunge Liet, den Lesarten sämmtlicher Handschriften und einem Wörterbuch*, edited by K. Bartsch (1870 *et seq.*); on this is based the smaller edition, with commentary, *Das Nibelungenlied*, re-edited by H. de Boor (1956). Two excellent monographs covering the whole problem are: A. Heusler, *Nibelungensage und Nibelungenlied*, 3rd ed. (1929; reprinted as 5th ed., 1955); and F. Panzer, *Das Nibelungenlied* (1956). Very helpful for detailed study of the elements of the story (*e.g.*, the figures of Siegfried and Brunhild) is the section, "Nibelungensagen," in H. Schneider, *Germanische Heldensage*, vol. i (1928). An English trans. of the poem by M. Armour is in Everyman's Library (1908). (K. C. K.)

NICAEA (modern IZNIK, in the *il* of Bursa, Turkey), an ancient city of Bithynia in Asia Minor, on the Ascanian lake (Iznik Golu). It was built on an old deserted site by Antigonus Monophthalmus (316 B.C.?) but soon afterward Lysimachus changed its name from Antigonia to Nicaea, calling it after his wife. Probably soon after Lysimachus' death (281) it was incorporated in the kingdom of Bithynia, whence it passed to the Romans (74). It flourished under the Roman empire, being on one of the main roads through Asia Minor, and continually disputed the title of metropolis of Bithynia with the provincial capital, Nicomedia.

After Constantinople became the capital of the empire, Nicaea grew in importance. It gave its name to the two ecumenical Councils of Nicaea (A.D. 325 and 787) and the Nicene Creed (*see* COUNCIL). The Seljuk Turks gained possession of it *c.* 1080 and it was the capital of the sultanate of Rum until its recapture in 1097 during the first crusade. After the capture of Constantinople by the Latins (1204) Nicaea became the seat of the Byzantine emperor Theodore I Lascaris and his successors until the recovery of Constantinople (1261). It was finally taken by the Ottoman Turks under Orkhan (1331) and continued to be of some importance, particularly for the production of polychrome pottery (*see* POTTERY AND PORCELAIN: *Islamic Pottery of the Near and Middle East*). Ruins of the Byzantine walls survive at the modern village of Iznik.

Nicaea was also the name of the Greek settlement founded at an unknown date from Massilia (Marseilles) on the site of modern Nice (*q.v.*).

NICAEA, COUNCILS OF. Two ecumenical councils of the Christian church were held at Nicaea (modern Iznik, Turkey). The first (also the first ecumenical council) was convoked by the emperor Constantine I in 325 and was concerned primarily with Arianism. The second Council of Nicaea (787) dealt chiefly with iconoclasm. *See* COUNCIL.

NICARAGUA (REPÚBLICA DE NICARAGUA), the largest country of Central America, lying between Honduras and Costa Rica which form its northern and southern boundaries respectively, and reaching from the Caribbean sea on the east to the Pacific ocean on the west. Its area, which is still undetermined because of incomplete surveys, is generally put at 53,398 sq.mi. The coast line extends about 300 mi. on the Caribbean, and 200 mi. on the Pacific. The Honduran boundary starts at Cabo Gracias a Dios, follows the Coco river inland and then at about 86° W. takes an imaginary line to the upper waters of the Negro river, which it follows to the Gulf of Fonseca. The Costa Rican boundary is, under treaties of 1858, confirmed in 1888 and settled in 1896, a line 2 mi. S. of the San Juan river and Lake Nicaragua.

PHYSICAL GEOGRAPHY

Geology.—Between Lake Nicaragua and the Pacific are Miocene lavas, calcareous shales and sandstones. In the Nicaraguan lowland, from the Gulf of Fonseca southeast to the mouth of the San Juan river, basic rocks are Miocene marine sediments, covered at both ends with Pleistocene and recent alluvium, and on the western margin by lavas and ashes of 30 Pleistocene volcanoes extending northwest to southeast from Cosigüina to Madera in Lake Nicaragua; highest volcano is Viejo (5,545 ft.). The central highlands are made up of Tertiary and of igneous and metamorphic rocks, overlain with volcanic ash in the northwest, Precambrian and Cretaceous intrusive granites in the north and northeast. The eastern lowlands consist of Pleistocene sediments, recent alluvium and areas of igneous rocks, sandstones and shales.

Relief and Drainage.—Level plains in western Nicaragua are fairly well drained by many short rivers flowing into the Pacific and into Lakes Managua and Nicaragua. The central highlands, 7,000 ft. high in the west, are rugged; eastward are lower undulating, plateaulike areas. From the divide, long rivers flow eastward: Coco (*q.v.*), navigable for 200 mi.; Grande, navigable in its lower course; Escondido, navigable 60 mi. to Rama City; and San Juan, navigable 100 mi. to Lake Nicaragua. The flat eastern plains have large swamps and coastal lagoons.

Climate.—The mean annual temperature in the eastern lowlands is 80° F., with little variation. The western lowlands have mean monthly temperatures of 80° to 86° F. Above 3,000 ft. they average 10° F. lower. East of the central highlands divide where there is no distinct dry season, annual precipitation decreases from 255 in. near San Juan del Norte (Greytown) to 100 in. on the Coco river. On the western flanks of the central highlands annual rainfall decreases sharply, from 80 in. to 53 in. in the lowlands; slopes of volcanic mountains receive 15 to 25 in. more; the period December through April is very dry.

Vegetation.—In the eastern lowlands and eastern parts of the central highlands, which are rainy all year, natural vegetation consists of slash pine, covering an expanse 40 to 100 mi. wide from Grande river to the northern boundary, and elsewhere, broadleaved evergreen forests of many species. These forests contain 80% of Nicaragua's timber. The western central highlands and middle slopes of volcanic mountains have deciduous hardwoods (oak and others) and subtropical grasses. The western lowlands comprise savannas and, along streams, deciduous forests.

Animal Life.—Inhabiting rainy, hot areas are many species of reptiles: crocodiles, lizards (iguanas and others), snakes and turtles. In forested areas deer are common. Wild life also includes the puma, jaguar, monkey and peccary. Many species of water and land birds, fresh-water and salt-water fishes (including mollusks), rodents and insects are abundant.

GEOGRAPHICAL REGIONS

Nicaragua may be divided into four clearly defined regions: (1) volcanic mountains and hills near the Pacific; (2) around and east of these mountains, the low plains and lakes of the great depressions, stretching from the Gulf of Fonseca to the mouth of the San Juan river; (3) the broad area of rugged central highlands extending from Honduras to near the San Juan; and (4) east of these, rolling plateaus and Caribbean lowlands.

The first two regions are characterized by much level and gently

sloping land, rich volcanic and alluvial soils, annual precipitation of 53 to 80 in., a very dry season of from four to six months and high temperatures. Together they comprise 62% of the country's population, most of its large cities, modern transportation facilities and industrial establishments. They produce about 75% of the nation's agricultural products and minerals, including clays and cement-making materials. Fertile valleys in the western part of the central highlands, inhabited by about 30% of the country's population, produce about 25% of the nation's coffee, tobacco, corn, beans, cotton and animal products; and highland mines supply nearly 25% of the mineral production. The rolling plateaus and Caribbean lowlands, poorly drained near the coast, comprise nearly half the area of Nicaragua. Hot and rainy all the year, they are largely uninhabited except along the coast and rivers, but their tropical forests supply most of the forest products exported and consumed domestically. In these lowlands three commercial banana districts, important until 1936, were largely abandoned as a result of Panama disease. (C. F. J.)

HISTORY

By the 15th century there were several Indian tribes living along the Pacific coast, whose cultural and linguistic ties were with the northwest, and other groups at a lower cultural level in the central and eastern regions, whose associations were with the southeast. The country's name is said to have been derived from that of Nicarao, an Indian chief whose people lived on the shores of Lake Nicaragua. Christopher Columbus, on his fourth and last voyage to the New World, landed on the east coast near modern Bluefields Sept. 16, 1502. Twenty years later Gil González de Ávila, with about 100 Spaniards and four horses, marched overland from Panama along the Pacific coast—reaching beyond Lake Nicaragua—but retired when he encountered hostility. Two more years passed before the conquistadores returned.

Colonial Period.—Nicaragua was the first of the Central American provinces to become firmly Spanish. Granada and León were founded in 1524 by Francisco Hernández de Córdoba, acting for Pedro Arias de Ávila (Pedrarias Dávila), governor of Panama. When Pedrarias came to León in 1526 he executed Hernández on suspicion of intrigue with Hernán Cortés, then in Honduras. Pedrarias as governor of Nicaragua (1527–31) developed an export trade in Indian slaves (who were used in Panama), had Río San Juan explored and tried unsuccessfully to establish his rule in Honduras and El Salvador. León was designated the seat of Central America's first bishopric in 1531, and the port of El Realejo developed in 1533. Rodrigo de Contreras, son-in-law of Pedrarias, was the second governor (1535–44); during his rule the province was placed first under the jurisdiction of a new *audiencia* at Panama (1538), then transferred to another at Gracias a Dios, Honduras (1544). Dissatisfaction with the Spanish code of New Laws of 1542 (which ended the Indian slave trade) and the loss of the governorship in 1544 led to a rebellion by the two sons of Contreras in 1550. Nicaraguan Bishop Antonio de Valdivieso was murdered and León, Granada and Panama city seized before the uprising was halted.

The province of León along the Pacific developed quietly as an agricultural colony for the next 250 years, with a variety of products from farm and forest. Trade was carried on at El Realejo, and from Granada via Lake Nicaragua and Río San Juan. Ships were also built at El Realejo. Except for two periods of buccaneer activity (in the 1660s and 1680s), life for Spaniards in the province was relatively easy, there being a plentiful supply of Indian labour. The province was a part of the *audiencia* of Guatemala, whose president, until 1786, directly controlled many Nicaraguan Indian communities through appointment of *corregidores* to manage their affairs. León had its own governorship which, in 1786, was raised to the status of an intendancy. By that time Spaniards, Negroes and persons of mixed blood were common residents of the "Indian" villages: Chinandega, Matagalpa, Managua and Masaya.

The country to the east and north, called the district of Tologalpa by the Spaniards, had a separate history because of the lack of Spanish settlement. Negroes moving in from the West Indies gave parts of the coast a new racial complexion. Buccaneer visits were frequent but friendly, and by mid-17th century a few permanent settlements were formed, including that at Bluefields. Later in the same century Great Britain formed an "alliance" with the chief of the Miskito tribe (of mixed Indians and Negroes), and from 1740 to 1786 the Mosquito coast (*q.v.*), containing many English residents, was counted as a British dependency. The Spanish prevented in 1780 a British attempt to ascend the San Juan and establish a transisthmian route.
